Authors of Volume 16

Dr D. Brewer
Research Associate, Department of Ornithology, Royal Ontario Museum, Toronto, Canada.

J. L. Copete
Freelance ornithologist, Barcelona, Spain.

Dr R. M. Fraga
Researcher, National Research Council of Argentina CONICET, Diamante, Entre Ríos, Argentina.

Dr S. L. Hilty
Research Associate, University of Kansas Natural History Museum and Biodiversity Institute, Lawrence, Kansas, USA; and Victor Emanuel Nature Tours, Austin, Texas, USA.

A. Jaramillo
Senior Biologist, San Francisco Bay Bird Observatory, Milpitas, California, USA.

S. C. Madge
Freelance wildlife consultant and writer; also, President, Cornwall Bird-watching & Preservation Society, Cornwall, England.

Dr A. P. Møller
Research Director, Laboratoire d'Ecologie, Systématique et Evolution, Université Paris-Sud, Orsay, France.

Dr R. I. Orenstein
Freelance consultant, Mississauga, Ontario, Canada; also, Affiliate Professor, Department of Environmental Science and Policy, George Mason University, Fairfax, Virginia, USA.

Professor J. D. Rising
Emeritus Professor, Department of Ecology and Evolutionary Biology, University of Toronto, Toronto, Canada; also, Research Associate, Department of Ornithology, Royal Ontario Museum, Toronto, Canada.

Dr P. G. Ryan
Associate Professor, Percy FitzPatrick Institute of African Ornithology, DST/NRF Centre of Excellence, University of Cape Town, Rondebosch, South Africa.

Foreword

Climate Change and Birds

Introduction

Most ornithologists older than 40 and living in the northern hemisphere will be able to remember a time just a couple of decades ago when spring migrants arrived considerably later, and many species that now breed at high latitudes did not do so. When these ornithologists are polled about their concerns for the future, they identify climate change as one of the most important issues. Climate change is currently occurring at an unprecedented rate, with severe consequences not just for birds but for humans and all other living beings alike. The immensity of the effects of climate change is on a scale that defies imagination, from the extensive current melting of the ice in Greenland and the Antarctic to the retreat of numerous glaciers around the world (Figure 1). Sea levels rose rapidly by 15–20 cm during the 20th century (Figure 2), with dramatic implications for hundreds of millions of people living in coastal areas; future projections of sea level rise vary from a few tens of centimetres to several metres, depending on the rate of ice melt in Greenland and the Antarctic. Global temperature increased by 0·7°C during the last century, but hardly at all during the previous 900 years (Anon. 2007c). Reconstructed climate variables covering more than 1000 years clearly show that climate change in recent years has been unprecedentedly rapid, with concomitant biological change. Further to climate warming, additional effects of climate change include an increased frequency of droughts, hurricanes and altered seasons. These changes are attributed by the majority of scientists to the effects of man-made changes to the atmosphere due to greenhouse gases (Hurrell & Trenberth 2010), with more than 98% of scientists with the largest scientific impact agreeing on this assessment (Anderegg *et al.* 2010). Thus, so-called climate sceptics constitute a tiny minority of scientists with little or no standing in the scientific community at large.

Climate change biology is a young science. The first paper that addressed this issue for birds, by Peter Berthold, only appeared 20 years ago (Berthold 1991). Since then there has been a dramatic increase in research on this topic, and almost 300 papers on birds and climate change were published in 2010 alone. Most of this research is purely descriptive, which is natural for a phenomenon where the basics still need to be fully elucidated. However, a purely descriptive approach raises concerns about causation versus correlation, and the possible impact of unknown variables on what might at first sight look like causal relationships. Climate change has increased linearly in many parts of the world, but so too have numerous other factors, such as intensification of agriculture, forestry and fisheries, expansion of urban areas, and release of pollutants. Caution needs to be taken in investigating the role of climate change alone, since any of these factors on their own or in combination may also affect living organisms.

Because of its obvious utility to decision-makers and politicians, who want to know the consequences of climatic change, research to date has been increasingly based on predictions or projections of future climate. This may be problematic, because models often only include a single climatic variable as a driver, making it unlikely that the projections will fit any future empirical observations. Especially given the influence of climate change sceptics, it is important to make careful conclusions that can face reality. Climate change research being shown up as ill-substantiated or tendentious will not benefit anyone: scientists, amateurs, decision-makers and certainly not the general public who must cope with a changing world. It is with this perspective in mind that I have written this overview of what we know and do not know about birds and climate change.

In this review, I first describe the major recent changes in climate that have already occurred, including extreme climatic events, to set the stage for the biological phenomena. Second, I review information on the annual cycle of birds and its component parts in relation to climate change, describing its effects on the start of the reproduc-

tive season, nest-building, egg-laying date, clutch size, incubation and nestling periods, number of clutches, reproductive failure, temporal mismatch between reproduction and food availability, duration of the breeding season, and dispersal. Third, I present an extensive review of the effects of climate change on bird migration, emphasising timing and duration of spring and autumn migration, and recent changes in arrival dates (their distribution, consistency and evolution, and how they may be influenced by geographical variation, breeding and winter effects, phenotypic plasticity and sex differences). Fourth, I describe how morphological traits such as secondary sexual characters, colour and body size have changed in response to climate change. Fifth, I assess to what extent the responses of individual birds to climate change may have effects at the population level, including population dynamics, interspecific competition, predation, host-parasite interactions and extinction risk. Sixth, I analyse studies of range expansion including observed and projected changes in distributions and range margins, and dynamics at the edges of populations. Seventh, I discuss changes in bird communities, and how generalist species have become predominant and communities are becoming ever more impoverished. Finally, I relate climate change to conservation issues by identifying which species are particularly susceptible to climate change, and briefly suggest means by which climate change effects can be mitigated and hopefully reversed. I have tried to find examples from a broad geographical range of species and systems. However, long-term time series data on migration, breeding and many other aspects of the life of birds are specialities of the subtropical, temperate and arctic climates of the northern hemisphere, and as yet few data are available from the tropics and the southern hemisphere.

Climate in a changing world

Climate has always changed on the long time-scale of millennia, but rarely so much and so rapidly as during the last century (Figure 3). This is disturbing, because while all living beings should supposedly be able to adapt to gradual climate change, the current speed of change may exceed what is possible for adaptation both by natural selection, and by plastic adjustments of individuals to changing conditions during their lifetime (known as phenotypic plasticity). During the ice ages, climate changed due to changes in precipitation caused by shifts in the Intertropical Convergence Zone, and this sometimes occurred at an abrupt pace, with temperatures increasing by 2–4°C from one year to the next (Steffensen *et al.* 2008). Current climate change, by contrast, is mainly linked to CO_2 and other greenhouse gases such as methane, and has caused an overall climate warming of 0·7°C during the last 100 years. However, temperature increases are unevenly distributed across the globe, and increases are particularly dramatic at high altitudes and latitudes (Figure 4). Hurrell & Trenberth (2010) provide an extensive overview of climate change, and interested readers can find further references to different aspects of climate change in that source.

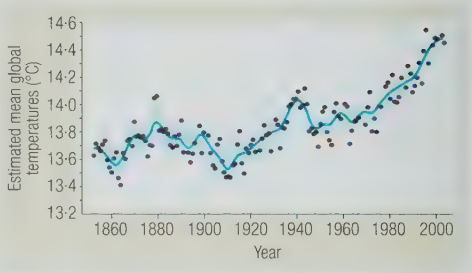

Figure 3
Change in mean temperature (°C) of the Earth during the last 150 years. Values are means, sliding averages (line) and 95% confidence intervals (wide band).
Adapted from IPCC (Anon. 2007c).

Climate change has been particularly marked in the Arctic. The diminution of the Arctic ice sheet since the 1970s has been unprecedented, with an average decrease of 7·4% per decade during 1978–2005. Since then, several years have set records in terms of ice melt, with a 20% reduction in ice cover in 2007 compared to 2005, which was the warmest year since measurements started in 1850. The effects of warming have been particularly pronounced for species dependent on or associated with sea ice. Likewise, effects of climate change in the Antarctic Peninsula have been marked; interestingly this has not been so for the Antarctic south of 65° S, where temperature has not shown any clear trends to date. In the Antarctic, changes are largely driven by the Southern Oscillation which governs sea surface temperatures and sea ice extent in the Southern Ocean, which in turn affects abundance of krill. The Southern Oscillation Index has shown a regime shift since the 1970s, resulting in less sea ice, with dramatic consequences for marine birds (Masson-Delmotte *et al.* 2003).

Climate change in the temperate zone has been almost as dramatic as in the Arctic. Temperature increases per decade have occurred unevenly in different geographical regions, and have been particularly strong in parts of Western Europe, Mongolia and China, but moderate or absent in large parts of North America, Eastern Europe and Russia. Decreases in snow cover in many regions of the northern hemisphere, especially in spring, have advanced spring phenologies. Precipitation has been increasing in eastern parts of North and South America, Northern Europe and Northern and Central Asia, while increasingly dry summers in Russia and North America have increased the frequency of forest fires.

In the subtropics, climate change has mainly affected temperature and precipitation: many areas are experiencing increasingly dry conditions and accelerating

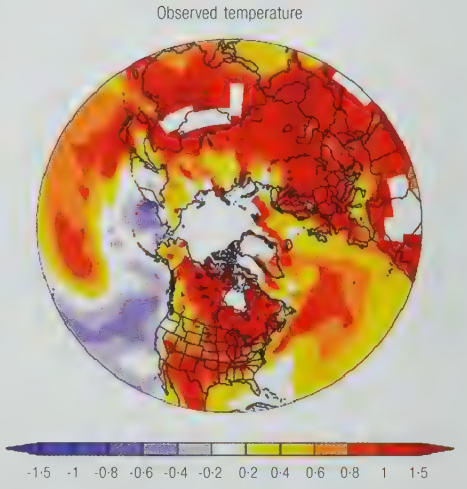

Figure 4
Temperature anomalies during 1998–2002 (°C) in different parts of the Earth.
Adapted from US Climate Change Science Program (Cook et al. *2010).*

desertification. Parts of the Mediterranean basin, the Sahel zone of Africa, southern Africa and southern Asia have all reported rises in desiccation.

In the tropics, climate change has been relatively modest in terms of temperature change. However, changes in sea level and the frequency of tropical storms are likely to have a negative effect on communities of birds in coastal areas, including many oceanic islands which have a disproportionately high fraction of endemic species. Indirect effects of climate change on birds in the tropics will arise as a consequence of displacement of human populations living in coastal areas, in concert with a projected expansion of such human populations.

Climate change may have its most profound effects on islands, where birds and other organisms have no other place to go. This is particularly serious because island bird communities contain disproportionately large fractions of endemic species. Many islands will become inundated completely owing to the rise in ocean levels, although rises in seawater levels will be uneven due to differences in water temperature.

The effects of climate change will also be particularly acute on mountain tops, where high-altitude species similarly have no other place to go once low-altitude vegetation and its associated fauna move up. Reductions in glaciers and ice caps were dramatic during the 20th century, and during the next century many glaciers in the tropics will disappear entirely.

Extreme climate change: Is it just more of the same, or is it different?

While there is no doubt that climate has changed dramatically during the last century, and in particular during the last couple of decades, there has been less research emphasis on extreme climate change. Not only will average temperatures and precipitation change, but extremes are predicted to become more frequent and pronounced. Extreme climatic events are defined by climatologists as rare events that occur at a frequency of 5% or less of the time as judged from the expected distribution of the climate variable (Anon. 2011b), and include droughts, heat waves and hurricanes. All of these are predicted to become much more common in most future climate scenarios (Anon. 2007c, Hurrell & Trenberth 2010). Already the frequency of heat waves has increased over the last 50 years, and there has also been a rapid increase in the number of warm nights. These changes have consequences for the tropical cyclones that since 1970 have increased in frequency and duration, although it needs to be borne in mind that older data before satellites became common may be of less rigorous quality (Trenberth 2007).

A consequence of extreme drought is increased risk of forest fires, as seen in large parts of Russia and Ukraine during the summer of 2010. The scientific study of the biology of extreme climatic events is in its infancy, precisely because such events by definition are rare. The obvious question arising is whether extreme events just constitute a continuation of the distribution of more commonly encountered events, or whether extreme events represent qualitatively different conditions that affect birds and other animals in a completely novel way (Møller 2011b).

Extreme climatic events are well known to biologists, as shown by effects of a violent snowstorm on House Sparrows (*Passer domesticus*) (Bumpus 1899) and powerful El Niño events on Darwin's finches (Grant, P.R. & Grant 2002a). Both of these events completely changed the phenotypic composition of the bird populations concerned, although they ultimately reverted to their former condition. Another common example is heavy mortality during migration (Newton 2007), as seen in Barn Swallows (*Hirundo rustica*) when passing mountain ranges in autumn, with dramatic consequences for life history and behaviour (Møller 2011b). Moreno & Møller (2011) recently reviewed the life history consequences of such extreme events and found that under normal conditions, complete reproductive failure occurred on average in 27% of breeding attempts; however, this rose to 79% during extreme events (Figure 5). Likewise, adult survival rate was three times worse during extreme events than under normal conditions. These findings clearly show that the intensity of selection is dramatically increased during extreme events, because only a small fraction of individuals will survive and reproduce and hence contribute to the next generation. Under such extreme natural selection, whether an individual survives or not often depends on the size of a given morphological character (known as "truncation selection"); for example, wing length may dictate survival during severe conditions on migration. This kind of selection has particularly strong effects on the composition of the population after a selective event.

Extreme climatic change may also increase variation in demographic parameters such as fecundity and survival. This has the effect of reducing the overall population

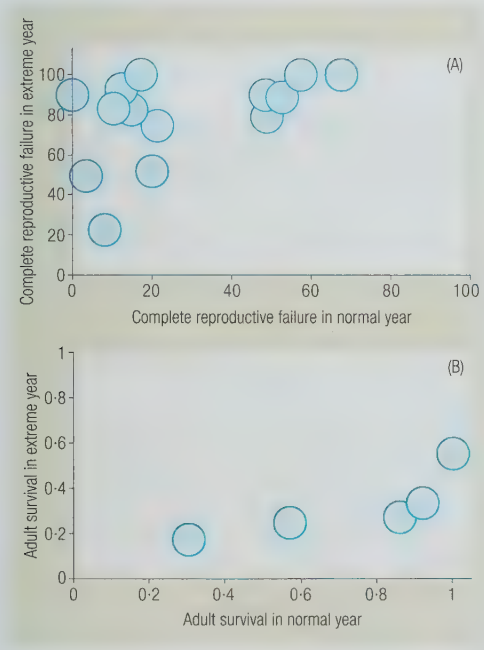

Figure 5
(A) Rate of reproductive failure and (B) adult survival rate of birds during extreme and normal weather conditions.
Adapted from Moreno & Møller (2011).

growth rate, even if mean rates of fecundity and survival remain unchanged. For example, European Shags (*Phalacrocorax aristotelis*) are coastal seabirds with high variation in annual survival rate caused by mortality due to severe winter storms (Frederiksen *et al.* 2008). A 43-year study revealed that survival rates varied greatly among years, especially in second-year birds and adults which were greatly affected by years with the strongest winds and heaviest rainfall. Shags and other cormorants do not have fully waterproof plumage as do other seabirds. This allows them to dive more efficiently, but also renders them very susceptible to the effects of cold and wet weather. Extreme weather conditions are predicted to increase in frequency, forecasting future population declines.

A particularly illuminating example of an extreme event is the heat wave that affected most of Western Europe, and France in particular, during 2003. This qualifies as an extreme event since temperature anomalies of up to +6°C occurred during April–August. It resulted in severely reduced primary productivity across Europe (Ciais *et al.* 2005) and an excess mortality of 2600 humans in France alone (Hémon & Jougla 2003). Intriguingly, bird species that were declining before 2003 declined particularly strongly in 2003, while increasing species increased particularly strongly in 2003 (Jiguet *et al.* 2006). It is therefore interesting to ask whether the natural thermal range of different species influenced how they responded to these temperature anomalies. To answer this question each species' thermal range was first determined from the range of temperatures experienced in the 50 warmest and 50 coldest grid cells within its European breeding distribution. This showed that bird species with the smallest thermal range suffered the largest declines in population size between 2003 and 2004, following the temperature anomalies of the summer of 2003 (Figure 6). These findings imply that the thermal ranges of birds reflect the past temperature fluctuations they have experienced in their evolutionary history, and thus their thermal adaptation to the environment. These findings also clearly imply that species with narrow thermal niches are particularly likely to be negatively affected by future heat waves. Indeed, modelling exercises suggest that future heat waves may lead to reductions in abundance and perhaps extinctions in many of the warmer parts of the world (McKechnie & Wolf 2009).

Effects of climate change on the annual cycle of birds

Numerous examples illustrate how dramatic changes have already occurred the in timing of reproduction and other annual events. These changes include an earlier start to singing by breeding birds in spring, advancing dates of migration and breeding, longer annual breeding cycles, and altered patterns of departure from the breeding grounds and, hence, autumn migration. Many birds can now be seen at times when and in places where they were previously never to be found. These observations raise questions about the organisation of the annual cycle, which is the subject of the next section. This is followed by a review of how climate change can affect when and where birds sing, as well as other aspects of the breeding cycle. Finally, this section is rounded off by discussing how climate change has caused reproductive timing to interfere with the other two major components of the annual cycle, migration and moult.

How rigid is the annual cycle and what determines the duration of its component parts?

All living organisms must schedule their life histories to fit within the time they have available. In birds this is reflected by the relative duration of reproduction, moult and migration in the annual cycle. Because the duration of each of these components increases with body mass, large-bodied species may come up against a threshold value at one year. If they are unable to fit these activities in less than a year, large species are forced either to reproduce every other year, to moult less than once a year, or partially to overlap migration and breeding with the start of gametogenesis (the production of gametes). The last mentioned means that sperm and egg production occurs during migration or arrival at the breeding grounds, while retaining energy reserves that allow an early start to reproduction (Hedenström 2006, Wingfield 2008). These trade-offs between different activities suggest that the timing of events in the annual cycle may be constrained, particularly in species with long migrations, moults or reproductive cycles. Species with very slow developmental rates of offspring, species with slow rates of moult (such as aerial foragers) and species with very long migrations may particularly suffer from constraints on the timing and duration of life history

events. Migrants are further constrained by typically short breeding seasons imposed by seasonal environments, especially when producing two or more clutches.

Moult and breeding, and moult and migration, rarely overlap, owing to the extreme costs of each activity. At northern latitudes, however, moult and breeding may overlap, and some passerines even become partly or fully flightless while breeding (Haukioja 1971b). On the other hand, some species of raptor, and other large-bodied species with prolonged moult periods, do extend moult across two or more years, apparently because fast moult is incompatible with prey capture (Rohwer, Ricklefs *et al.* 2009). These examples underscore the severe constraints on the timing of annual events.

The timing of moult determines when subsequent components of the annual cycle can take place. For example, migration with moulting feathers is energetically much more expensive than migration with full plumage. We currently know very little about changes in the timing of moult by migrants when their timing of migration has changed. Superficially, we should expect that earlier migration would allow moult to start earlier. However, Barn Swallows of Eastern European breeding origin wintering in South Africa have delayed their moult during the last eleven years, resulting in a delay in timing of spring migration (Møller, Nuttall *et al.* 2011). This would prevent an early departure from the South African winter quarters. The timing of the start of moult (as well as the maturation and regression of gonads) is under photoperiodic control, and therefore should not change if the photoperiod remains unchanged in the migrants' winter quarters. That is the case even when a photoperiodic response is fine-tuned by factors such as temperature at the breeding grounds (Dawson 2005, 2008). Moreover, migratory responses to climate change could be constrained by genetic correlations between timing of egg-laying and timing of autumn migration (Coppack *et al.* 2001), and between onset of autumn migration and timing of juvenile moult (Pulido & Coppack 2004). This is because these genetic correlations mean that selection for earlier laying would simultaneously result in selection for earlier autumn migration. Therefore, there are multiple mechanistic constraints on whether and to what extent the timing of moult can respond to climate change.

Start of the breeding season and singing

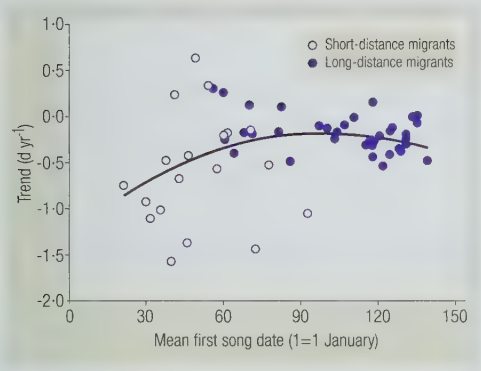

Figure 7
Rate of advance in date of first singing by birds in Parchim, Germany, in relation to migration distance. The line is the polynomial regression line. Adapted from Rubolini et al. *(2010).*

The start of the breeding season is commonly ascribed to increasing levels of hormones and their influence on reproductive behaviour such as singing and other sexual display. However, the empirical evidence suggests that these mechanisms can evolve to change in response to earlier springs. Schmidt & Hüppop (2007) analysed trends in first song dates of 56 resident and migrant bird species for 43 years during a period of rapid climate change. First song dates advanced by 0·3–0·6 days per year, similar to the advances in arrival date of migrants. A key conclusion from this unique dataset is that both migrants and non-migrants responded to climate change by advancing singing date. This suggests that migration appears not to impose a constraint on response to climate change by preventing long-distance migrants from responding to climatic changes at the breeding grounds until after spring arrival. Rubolini *et al.* (2010) compared changes in onset of singing in spring in short- and long-distance migrants using the same dataset. Species that migrated a distance of less than 4° latitude (450 km) advanced their first song dates more than long-distance migrants (Figure 7). This advancement was explained by increasing spring temperatures. However, species laying two or more clutches per year showed a stronger advance in first singing date than species laying only a single clutch. This result implies that more than a single clutch per year imposes a stronger selection pressure for earlier start of reproduction. Interestingly, the effect of temperature on first song date was unrelated to migration status. Taken together, these findings imply that the difference in the temporal trend between short- and long-distance migrants was mainly due to environmental cues regulating departure of migrants from the wintering areas, rather than to differential responses of first song date to local temperatures.

Climate change may also affect the environment that birds use for singing. Birds typically sing from exposed positions in the vegetation even when such positions make them vulnerable to predators. An important consequence of recent climate change is that bushes and trees are leafing much earlier in spring than just a couple of decades ago. This has consequences for the choice of song-posts, because early-sprouting foliage imposes greater interference to sound transmission, making it more favourable to sing from higher positions (Møller 2011a). Indeed, the average song-post height of various species of birds increased by 18% (or 1·2 m) between 1986–1989 and 2010 in a Danish study. These changes were absent for species singing in the herb layer, moderate for species singing in bushes, and most pronounced for species singing in trees, as expected from the effect of earlier leafing. In addition, species with increasing popu-

lation trends and species with sexually dichromatic coloration (and hence more intense competition for mates) were those that increased song-post height the most. These findings suggest that climate change can affect vocal behaviour of birds not only in terms of phenology, but also in terms of habitat use.

Nest-building

Nest-building takes up a significant amount of time in the reproductive cycle. A study of 200 European species found that females, males or both sexes spend from two to 105 days on the activity. Nests are sometimes much larger than required for containing and protecting eggs and young; nests of species in which both sexes contribute to building are on average twice as large as those of species where females build single-handedly (Soler *et al.* 1998). This implies that in some species nest size and building plays a role in mate choice and sexual selection. In the Barn Swallow, pairs consisting of a male with a short tail that is less attractive to females build larger nests than pairs with a long-tailed male. Interestingly, nest size has decreased over time by a factor of three owing to the negative effect of climatic conditions in North Africa on the survival of short-tailed, poor-condition males, which build larger nests over longer periods than long-tailed, good-condition males (Møller 2006). These findings suggest that not only is nest-building time-consuming and likely to constrain the speed of breeding, but also that it may be influenced by non-random selection imposed by climate change.

Laying date

Timing is everything when it comes to reproduction. Since timing of migration and timing of singing has advanced in response to climate change in many different bird species, it is not surprising that equally many species have started to lay eggs earlier, as in the striking case of the Northern Lapwing (*Vanellus vanellus*) (Both *et al.* 2005). Dunn & Winkler (2010) reviewed the literature and showed that 59% (against the random expectation of 5%) of 68 species mainly from Europe and North America have significantly advanced their laying date. Likewise, 79% advanced their laying date during the last decades when temperatures increased. The rate of advance was 0·13 days per year. This can be compared to the rate of advance of 0·39 days per year for phenology in general in the UK (Thackeray *et al.* 2010) and a rate of advance of 0·37 days per year for first arrival date of migrants (Lehikoinen *et al.* 2004). Because the rate of change for laying date is only a third of the rate of change for migration and for phenology in general, and because migration phenology is delayed compared to general phenology, these data suggest that the breeding date is lagging severely behind.

While there is general consistency in the advancement of laying date among species, implying that the same species respond similarly at different sites, there is also additional variation between populations of the same species. Several studies have shown heterogeneity in response between populations, with those encountering the largest degree of increase in temperatures also showing the strongest responses (Dunn & Winkler 1999, Sæther *et al.* 2003, Visser *et al.* 2003, Both *et al.* 2004, Both & te Marvelde 2007), even at very local scales of a few kilometres (Møller 2008b). This effect of temperature is causal, since experimental increases in temperature advance the breeding date of captive birds (Visser, Holleman & Caro 2009). Therefore, selection for earlier laying should increase as optimal conditions for breeding advance due to climate change.

Much of the variation in the advancement of laying date lies among species (rather than among different populations of the same species, for example), and some of this can be explained by differences in ecology. The single most important factor explaining advancement in laying date is the number of clutches produced per year (Dunn & Winkler 2010). While species with a single clutch advanced their laying date by 0·19 days per year, species with multiple clutches only advanced theirs by 0·06 days, or less than a third. This has been clearly shown for tits (Visser *et al.* 2003, Husby *et al.* 2009). This difference is expected because laying two or more clutches constitutes a more difficult problem, in terms of adjusting laying date to the peak of food abundance, than does laying a single clutch. Another ecological determinant of advancement in laying date is trophic level. Across all organisms, species at higher trophic levels, such as consumers of herbivores (predators) and super-predators (predators of predators), have shown slower phenological responses to climate change than species at lower trophic levels (Thackeray *et al.* 2010). Indeed, in birds, Dunn & Winkler (2010) showed greater advancement in laying date for herbivores (0·45 days per year) compared to insectivores (0·11 days per year) and carnivores (0·14 days per year), although these differences were not statistically significant (see also van der Jeugd *et*

al. 2009). Surprisingly, there was no difference in advancement of laying date in relation to migratory behaviour. Residents and short-distance migrants advanced their start of laying at a rate that did not differ from that of long-distance migrants. This lack of difference in laying date with respect to migration behaviour may appear to be contrary to what would be expected from the observed delay in arrival for long-distance migrants caused by climate change (Lehikoinen & Sparks 2010), and future research will be needed to resolve the effects of climate change on the simultaneous evolution of migration and breeding phenology.

It is usually advantageous to lay early, because early hatching coincides with the annual food peak while late laying prevents parent birds from benefiting from the annual peak in food abundance. In addition, early reproduction results in more time for offspring to develop independence before migration and/or moult. These benefits imply that there is a greater fitness advantage to early laying, and many studies have found such an affect. However, the pattern is not clear-cut. Dunn & Winkler (2010) reported that selection for early breeding has increased in recent years in only half the studies to date, in species as diverse as European Pied Flycatchers (*Ficedula hypoleuca*) (Figure 8; Both & Visser 2001), Great Tits (*Parus major*) (Visser *et al.* 1998, Charmantier *et al.* 2008), Barnacle Geese (*Branta leucopsis*) (van der Jeugd *et al.* 2009), Common Murres (*Uria aalge*) (Reed *et al.* 2009) and Arctic Terns (*Sterna paradisaea*) (Møller *et al.* 2006a). However, equally many studies have shown no evidence of change in directional selection (review in Dunn & Winkler 2010).

What evolutionary mechanism underlies such changes? Shifts in laying date could result either from evolutionary change (changes in the genetic composition of the population), or through phenotypic plasticity (individuals changing their behaviour according to environmental conditions). The foregoing studies have generally suggested that despite the fact that natural selection favours an advancement in laying date, there is no evidence of evolutionary change, and responses to selection have been entirely phenotypically plastic (Charmantier *et al.* 2008).

Egg-laying and clutch size

While the literature on phenology is extensive, there is much less information on change in clutch size. Because early laying and large clutches tend to go together both within and across species, we should expect increasingly earlier laying to be associated with increasingly larger clutch size. However, while studies of European Pied Flycatchers and Barn Swallows have shown such increases (Figure 9; Winkel & Hudde 1997, Møller 2002), studies of Collared Flycatchers (*Ficedula albicollis*), Great Tits and Common Blue Tits (*Cyanistes caeruleus*), Tree Swallows (*Tachycineta bicolor*), Eastern Bluebirds (*Sialia sialis*) and Red-winged Blackbirds (*Agelaius phoeniceus*) have not (Winkel & Hudde 1997, Winkler *et al.* 2002, Sheldon *et al.* 2003, Torti & Dunn 2005). Dunn & Winkler (2010) suggested three explanations for a lack of increase in clutch size. One possibility is that in warmer years it is easier for individuals to lay early, but this shift is not associated with an increase in clutch size because the association between clutch size and laying date has changed. Second, laying date may advance without clutch size increasing if a larger fraction of females of poor quality (who are unable to achieve large clutches) enter the population under such benign environmental conditions. A final possibility is that laying date has a greater impact on total fitness than clutch size, due to the negative effects of mistiming laying in relation to the food peak. Therefore, laying another or a few more eggs would delay hatching and run the risk of further mistiming. There have been no attempts yet to evaluate these alternative explanations.

An additional consequence of climate change for egg-laying is that the difficulty of finding sufficient resources to produce eggs should ameliorate as spring weather becomes warmer. One measure of this difficulty is the incidence of deviations from the normal rule of one egg being laid daily, since birds may skip a day if insufficient resources for egg production are available. Indeed, there was a decrease in laying interruptions in the Common Blue Tit by 0·58 days per egg during 1979–2007 (Matthysen *et al.* 2011). By contrast, no significant change was detected in Great Tits, as expected since a Great Tit's clutch is a smaller proportion of its body weight and therefore less costly to produce.

Duration of incubation and nestling periods

Changes in the duration of developmental periods may also allow birds subtly to adjust the timing of breeding in relation to changing environmental conditions. The

incubation period is largely determined by the developmental requirements of the embryo, which should be fixed in relation to climate change. Nonetheless, one study suggested that the incubation period of Great Tits has increased by on average two days in response to climate change; together with clutch size and onset of incubation, this enabled tits to fine-tune hatching date in relation to food peaks (Cresswell & McCleery 2003). Interestingly this effect was not statistically significant in a study of Common Blue Tits and Great Tits in Belgium (Matthysen *et al.* 2011), showing that different populations do not respond to climate change in the same way.

The only evidence to date on changes in nestling period also comes from tits: Matthysen *et al.* (2011) showed that in recent years, the duration of the nestling period has on average decreased by 1·5 days for Common Blue Tits, and by 1·3 days for Great Tits. Obviously neither the incubation nor nestling periods can dramatically adjust timing of breeding to altered phenology of food, although they may be contributing factors, as shown for incubation in Great Tits.

Number of clutches

Many species lay more than a single clutch per year, because the season is sufficiently long to permit multiple reproductive events. However, in order to benefit from a single annual food peak, the timing of these clutches may have to be relatively early for the first clutch and relatively late for the second clutch, compared to an optimally timed single clutch (Crick *et al.* 1993). This should particularly be the case for residents but less so for migrants, which are constrained by the twice-yearly migrations between breeding areas and winter quarters. If the problem of fitting two (or more) clutches into a single breeding season is an important factor determining reproductive success, then increasing spring temperatures should allow birds to space their clutches better, without sacrificing their own survival prospects. Indeed, warming springs have allowed Barn Swallows to start breeding earlier in recent years, thereby increasing the duration of the interval between first and second clutches by more than ten days during a period of only 40 years (Figure 10; Møller 2007a). This less "hectic" breeding schedule, with a longer time between the start of the first and the second clutch, allows females to recover from the large investment in first clutches. Pairs with a longer inter-clutch interval can increase their reproductive output without compromising the survival of reproducing females. This study shows that there is scope for changes in the timing of multiple reproductive events when climate changes.

Barn Swallow
Hirundo rustica
[Illustration by Hilary Burn]

Can climate change also influence the incidence of second clutches, as well as their timing? There is marked geographical variation in the frequency of second clutches among species, and even among populations within species. For example, the frequency of second clutches in the Great Tit ranges from zero in high-latitude populations, and populations in the UK, to more than a third in some other populations (Sanz 2002). Some studies have shown a decreased incidence of second clutches with increasing temperatures, while others have not. As noted above, populations that lay two clutches have to optimise the timing of laying of these two clutches, causing the first to be too early and the second to be too late for the main single food peak. For example, caterpillars are the main food source for breeding tits. Increasing spring temperatures will advance the development rate of caterpillars, causing an advancement in the date of the food peak, but also a reduction in the width of the food peak, thereby reducing the reproductive value of second broods. In this situation, when the width of the food peak is reduced, females should adjust their laying date of the first clutch to the food peak, delaying the laying date relative to the optimum when two broods are attempted, and in that way counteracting the effect of temperature on advancement of laying date due to advancement of the food peak. Visser *et al.* (2003) predicted that laying date should advance in populations with either no second clutches or a stable proportion of second clutches, because the first clutch laying date is not a compromise between the laying date of the first and the second clutch. They also predicted that laying date will have advanced to a lesser extent or not at all in populations with a decreasing frequency of second clutches. That was indeed the case for both Great Tits and Common Blue Tits: populations that experienced a decline in the proportion of second clutches experienced greater advancements in laying date (Figure 11). These findings suggest that exactly how birds might optimally adjust laying date to climate change depends on the trade-offs between optimal timing with respect to the food peak, and the frequency of multiple clutches.

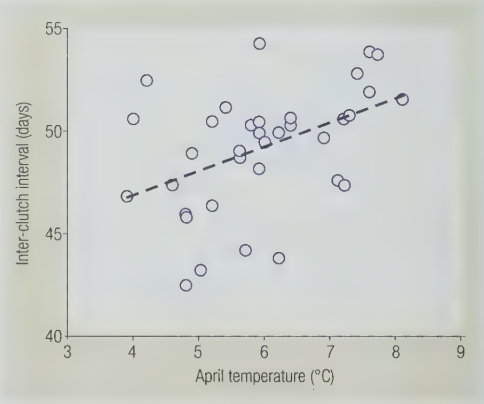

Figure 10
Duration of the interval (days) between start of laying of the first and the second clutch in the Barn Swallow (Hirundo rustica) *in Denmark in relation to April temperature (°C). The line is the linear regression line. Adapted from Møller (2007a).*

However, the patterns just described for tits may not be general. Barn Swallows and Northern House Martins (*Delichon urbicum*) show large differences in the frequency of second clutches among European populations, declining markedly with increasing latitude (Møller 1984). Although the breeding dates of both species have advanced consid-

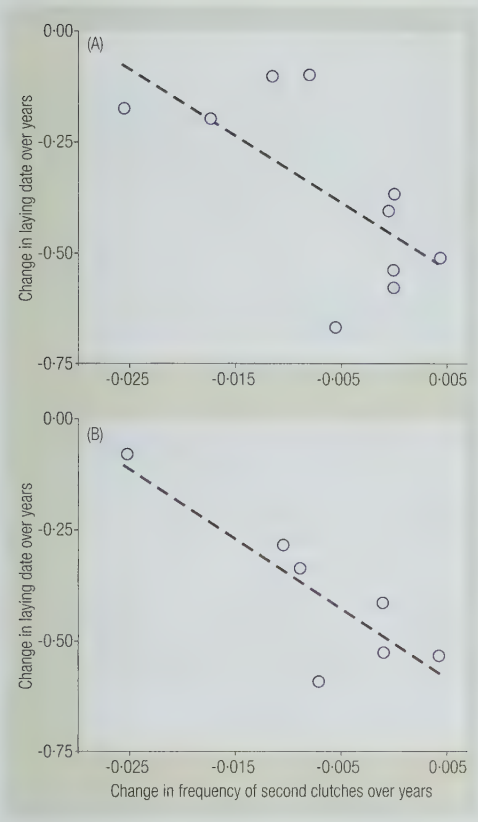

Figure 11
Decline in the frequency of second clutches in Great Tits (Parus major) *and Common Blue Tits* (Cyanistes caeruleus) *in relation to advancement in laying date of the first clutch. The lines are the linear regression lines. The negative relationships imply that populations that have advanced their laying date the most are those that have increased the frequency of second clutches the most. Adapted from Visser* et al. *(2003).*

erably during the last 20 years associated with climate change, there has been no change in the frequency of second clutches whatsoever (Møller 2002 and unpublished data).

Reproductive success

While there are many data on changes in phenology and few data on changes in clutch size, there are even fewer data relating changes in reproductive success to climate change. An earlier start of reproduction and a longer growing season may reduce costs of reproduction. Thus under certain circumstances climate change may even improve reproductive success: as noted above, warming spring temperatures have enabled an increase in the interval between first and second clutches in Barn Swallows, and Møller (2007a) has shown that reproductive success almost doubled between clutches with the shortest and longest intervals between first and second clutches. Female Barn Swallows that invest more in reproduction than males benefitted from this longer breeding season and longer interval between clutches by no longer paying a viability cost of producing a second clutch, as they did just a couple of decades ago.

Reproductive success may also be affected by climate change in unexpected ways. In the Barn Swallow, the frequency of unmated males has decreased through improved male survival caused by improved environmental conditions in North Africa during spring migration (Møller 2004b). Unmated males can secure reproductive success through infanticide at nests that are not well guarded by the owners, causing a divorce and subsequent remating by the female with the infanticidal perpetrator. Incidence of infanticide has decreased with climate change in North Africa (Møller 2004b). Because fewer males remain unmated now than before climatic changes in North Africa, the frequency of infanticide has changed from affecting 5% of all nests to being virtually absent in recent years, thus improving reproductive success with respect to this parameter (Figure 12; Møller 2004b). Thus, the effects of climate change on behaviour and reproductive success are often idiosyncratic and difficult to predict.

Mismatch between food, breeding date and optimal timing of reproduction

Animals typically breed at times when the probability of successful reproduction reaches a maximum (Lack 1954). Therefore, breeding is timed such that food requirements for offspring are typically maximal when food availability peaks. There are numerous examples of such a match between supply and demand, since selection has favoured those individuals that use cues that ensure breeding at an optimal time, and therefore leave the most descendants to the next generation. A classical example of reproductive match between timing of breeding and food supply is provided by Great Tits and their caterpillar prey, which show a marked peak in abundance in spring well after laying, when chicks are being fed (Figure 13).

Obviously, however, matching reproductive phenology to food availability represents a challenge, mainly because the phenology of more than one organism is involved, providing ample opportunities for errors (Visser *et al.* 2004, Both 2010b). Many species have responded to increasing spring temperatures by laying earlier, although not early enough to maintain synchrony with their caterpillar food (Buse *et al.* 1999, Visser *et al.* 2006). Mismatch in timing of breeding by Great Tits results in a reduced probability of offspring being recruited into the population (Visser *et al.* 1998). The impact of climate change on timing of Great Tit reproduction has differed among populations, with the Oxford (UK) and Antwerp (Belgium) populations having become better synchronised than before (Charmantier *et al.* 2008, Matthysen *et al.* 2011), whereas the Hoge Veluwe (Netherlands) population has become less synchronised. Mistiming may arise from a number of different mechanisms, including timing of food changing more than timing of breeding, the food peak becoming more spread in time (thus reducing the effects of mistiming), or the food peak becoming more concentrated in time (thus increasing the effects of mistiming) (Both 2010b). However, caterpillars and tits do not live in a vacuum, but coexist with different food plants, competitors and predators. Indeed, Both *et al.* (2009) showed that while the caterpillar emergence date has advanced considerably, and the breeding dates of three species of tits and European Pied Flycatchers have all advanced (albeit to a lesser degree than caterpillars and to a different degree in different bird species), the timing of budburst of oaks (*Quercus* spp.) and of breeding by Eurasian Sparrowhawks (*Accipiter nisus*), which eat tits and flycatchers, has not changed at all (see also Nielsen & Møller 2006). Thus mismatch is not just a question of optimal individual decisions and optimal timing of life history events to the environment and to climate change, but also of optimal timing to the web of life that surrounds all living beings.

Great Tit
Parus major
[Illustration by Hilary Burn]

Although studies have revealed mismatches in timing of reproduction relative to food abundance in many species, equally many species have shown no such mismatch (Dunn *et al.* 2011). The reasons for such interspecific differences remain poorly understood. There are limits to optimal behaviour by birds because there are limits to local adaptation. For example, gene flow at a local scale may prevent individuals from behaving optimally, if individuals adapted to timing of food availability in other populations immigrate from elsewhere (Dhondt *et al.* 1990). Likewise, evolutionary lag may prevent birds from catching up with ever-changing peaks in food abundance. There has always been mistiming of phenological events, and that will remain the case with or without climate change. So when should we expect mismatch and when should we not? At which level of climate change should we expect mismatch? Visser & Both (2005) suggested that an appropriate yardstick for assessing the level of mistiming is the extent to which a species adjusts its timing of reproduction to the availability of its primary food. However, every individual of every species is predicted to have to time its reproduction to numerous factors such as prey, predators, competitors or parasites. Clearly, these adjustments cannot all be simultaneously maximised; we should rather expect the temporal match to different species to depend on the strength of selection that each species imposes. Moreover, degree of temporal match should also perhaps depend on the availability of cues that can influence decision-making by individuals of any given species.

A different way of addressing the question about temporal mismatch is to test for changes in phenological response to climate change at different trophic levels, because overall mismatches between trophic levels would increase the possibility of widespread mismatches between particular interacting species. Thackeray *et al.* (2010) analysed more than 25,000 rates of phenological change for 726 species in the UK, and found consistent advances in phenology by 0·39 days per year. Such widespread and homogeneous advance is suggestive of a common external driver, namely climate change. This advancing phenology also paralleled the rate of change in temperature, as one should expect if climate change was the main driver. Importantly, the change in phenology depended on trophic level: secondary consumers such as Great Tits showed a slower response of 0·22 days per year compared to the response of primary consumers such as caterpillars (0·43 days per year) and primary producers such as oaks (0·40 days per year). These findings raise significant concern about the synchrony of different trophic levels, and hence the risk of breakdown of interspecific interactions and ecological communities.

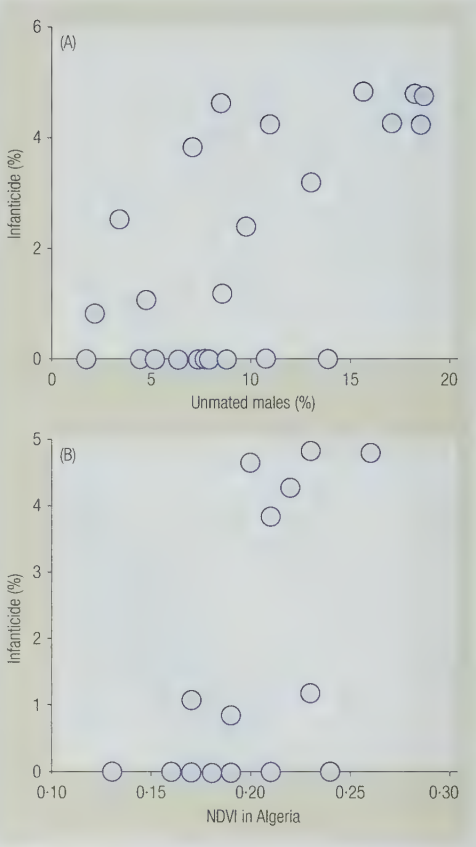

Figure 12

Duration of the breeding season

The breeding season is defined as the period during which environmental conditions allow adults to rear offspring successfully. As described above, the timing of breeding may not always be optimal with respect to food because very early breeding may allow more clutches to be produced during a year, hence temporally displacing both first and second clutches from the time when food availability peaks. Because the growing season at lower trophic levels (i.e. plants) has advanced due to climate change (Schwartz *et al.* 2006), we should also expect the breeding season to advance. That would result in a longer breeding season if more broods were produced, or the interval between broods expanded. Møller, Flensted-Jensen *et al.* (2010) analysed change in the duration of the breeding season for 20 bird species in Denmark. There was considerable interspecific variation, from a shortening of the breeding season by 36 days in the Sandwich Tern (*Thalasseus sandvicensis*) to an extension by 36 days in the Common Woodpigeon (*Columba palumbus*). This change in the duration of the breeding season was directly related to mean temperature during the month when breeding started, with species breeding in cooler months experiencing increasingly longer breeding seasons. Long-distance migrants have not responded as strongly in terms of arrival phenology as short-distance migrants (Lehikoinen & Sparks 2010), so we might expect a different change in duration of the breeding season between migrants and residents. Surprisingly, there was only a weak effect of migration distance, with small reductions in the duration of the breeding seasons of long-distance migrants over the period that climate change has occurred, rather than large increases as we might expect. While species laying multiple clutches per year increased the duration of the breeding season by 0·43 days per year, species with single clutches actually reduced the duration of their breeding season by 0·44 days per year (Figure 14). This effect can be expected because an increase in temperature causes a shortening of the period of full gonadal maturation (Dawson 2005). Therefore, breeding seasons show considerable flexibility in duration depending on the number of clutches produced per year.

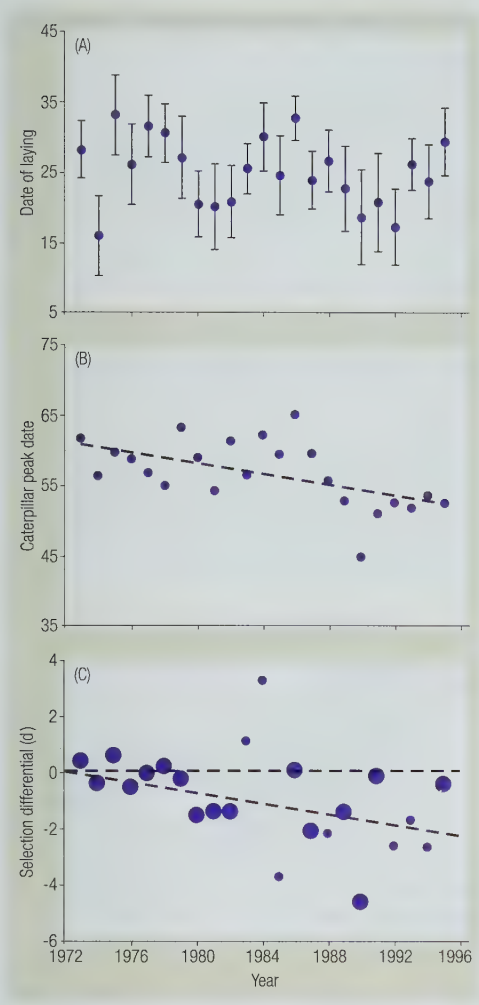

Figure 13
(A) Laying date (1=1 April), (B) caterpillar peak date and (C) selection differential on laying date in Great Tits (Parus major) *in the Netherlands. While date of laying has not advanced, the peak date for caterpillars had advanced, with the consequence that selection for early laying has increased (i.e. has become more negative).*

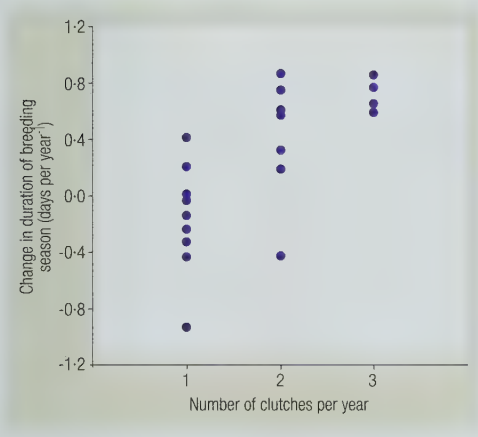

Figure 14
Rate of change in the duration of the breeding season (days per year) in relation to number of clutches produced per year for different species of birds in Denmark.
Adapted from Møller, Flensted-Jensen et al. *(2010).*

Evidence for a role of the number of clutches in response to climate change also comes from studies of number of clutches and migration. Bird species with multiple clutches per year advanced their spring migration in Hungary more than species with just a single clutch (Végvári *et al.* 2010).

Dispersal

Dispersal may affect adaptation to changing climatic conditions because gene flow from populations at different latitudes that already experience warmer climates may promote local adaptation; conversely, gene flow may erode local adaptation. Recent studies suggest that dispersal propensity and habitat breadth may increase at range margins, thereby increasing the rate of range expansion (Thomas *et al.* 2001) and perhaps thus hastening responses to climate change. Unfortunately, there are very few studies that have related dispersal propensity of birds to climate change. Arctic Terns are long-distance migrants that breed in temperate and Arctic regions of the northern hemisphere, and winter in Antarctic parts of the Southern Ocean. In this species, natal dispersal distances from the site of hatching to the site of first breeding have increased from a mean of 15 km in the 1930s to almost 90 km in the 1990s in a marginal Danish population (Figure 15; Møller *et al.* 2006b). However, this study also found that long natal and breeding dispersal distances were costly as they delayed reproduction in a given year. Their incidence was related to climatic conditions both on the breeding grounds and in the winter quarters: natal dispersal distance depended on climatic conditions in the year of hatching and the year of breeding, but breeding dispersal distance was only affected by climate conditions in the second year of the dispersal event. Thus, while natal dispersal distance depended on conditions in the breeding areas, breeding dispersal also depended on the weather in the Antarctic winter quarters, showing that via dispersal, the extent of gene flow was affected by climate in two different parts of the annual range.

Indirect estimates of dispersal can also be obtained from stable isotope profiles, since the isotopic fingerprint of a moulting site is recorded in the chemical composition of feathers. American Redstarts (*Setophaga ruticilla*) grow or moult their feathers at the breeding grounds. Juveniles winter in either favourable mangrove habitat or inferior scrub, with the latter birds departing on spring migration later than the former. Early departure allowed mangrove birds to migrate relatively short distances to their breeding grounds and settle there to benefit from early spring phenology and an early food supply (Studds *et al.* 2008). In contrast, juvenile American Redstarts wintering in secondary scrub habitat left late on spring migration, forcing them to migrate further north and thereby risk a temporal mismatch between food availability and timing of breeding. Adults showed highly consistent stable isotopic profiles of their feathers among years, suggesting that they bred at the same sites once having dispersed during natal dispersal.

Another consideration in relating dispersal to climate change is that dispersal decisions may differ among populations, resulting in divergent patterns of selection (Balbontín *et al.* 2009a). Barn Swallows from a Spanish and a Danish population differed in their dispersal propensity because Spanish birds were six times as likely to be philopatric (to breed in the same place as were they hatched) as Danish birds. Environmental conditions in Africa as reflected by the Southern Oscillation Index differentially increased philopatry in Spain, while decreasing philopatry in Denmark. Thus, population differences in dispersal propensity as mediated by climatic conditions in the winter quarters (Southern Oscillation Index) may help maintain local adaptation and prevent mixing of populations. Furthermore, such differences may prevent homogeneous responses to climate change, even when the same climatic conditions (Southern Oscillation Index) are acting on different breeding populations.

Bird migration under climate change

Studies of bird migration provide some of the clearest examples of the effects of climate change. However, they also illustrate many of the problems encountered when analysing and interpreting biological data relating to climate change.

Timing and duration of spring migration

Starting in 1749, Linnaeus (1757) organised the recording of the first arrival dates of birds in Finland (Figure 16), which have been continued ever since. These long-term

phenological data for first arrival dates are particularly illuminating for several reasons. First, they even show patterns corresponding to shorter-term changes in climate, such as the two relatively brief periods of warming during the years 1860–1889 and 1930–1940 (Lehikoinen *et al.* 2004). Second, all species tend to change in unison, so that periods with early arrival are consistent among species. Third, birds advanced their arrival dates in recent years in a manner consistent with current climate change. Even longer phenological time series exist for cherry blossoms in Kyoto, Japan, dating back to the 9th century (Aono & Kazui 2008), showing that timing of flowering now is earlier than it has been during the period 850–2010.

Migration is an adaptation to the exploitation of seasonal environments. Birds may change from migrants to residents over a few generations if environmental conditions during winter allow. Many populations of northern species that were completely migratory just 100 years ago are now almost exclusively resident, for example Hooded Crow (*Corvus cornix*), Common Blackbird (*Turdus merula*), European Robin (*Erithacus rubecula*), Dunnock (*Prunella modularis*) and Common Chaffinch (*Fringilla coelebs*), all of which are now residents in central and northern Europe (Berthold 2001, Newton 2008). The optimal timing of arrival depends on its benefits in terms of competition for territories and mates and the possibilities of early breeding, the production of an additional clutch and recruitment of the offspring to the next generation, and its costs in terms of risk of mortality from adverse weather during spring arrival (Jonzén *et al.* 2007).

Species differing in migration ecology have responded differently to climate change, with long-distance migrants responding less than short-distance migrants (Lehikoinen *et al.* 2004, Lehikoinen & Sparks 2010). There are two main reasons why long-distance migrants might be expected to arrive later relative to the phenology of their breeding grounds: first, timing of migration may be under the influence of conditions in the winter quarters often thousands of kilometres away from the breeding areas, and second, because endogenous rhythms determining departure for the breeding grounds are responding only weakly or not at all to climate change. For example, European Pied Flycatchers in the Netherlands have shown a steadily advancing breeding date over the past 20 years but no advance at all in their spring arrival date (Figure 17; Both & Visser 2001).

Earlier spring arrival may be permitted by such factors as faster migration, earlier autumn departure, and the use of wintering areas closer to the breeding grounds. For example, numerous North American species have been shown to migrate more quickly across the US in warmer years (Marra *et al.* 2005). Several studies also suggest that changes in stopover time and fuelling time are possible when climatic conditions allow (Bairlein & Hüppop 2004). Barn Swallows may rapidly change their departure date from their South African winter quarters in response to changes in the annual cycle of breeding, migration and moult (Møller, Nuttall *et al.* 2011). Examination of the geographical distribution of ringing (banding) recoveries reveals that migratory birds now winter further north than they used to do just a few decades ago (Siriwardena & Wernham 2002, Fiedler *et al.* 2004, Visser, Perdeck *et al.* 2009, Ambrosini *et al.* 2011). These findings of rapid change in migration schedules are supported by recent increases in the frequency with which tropical migrants such as Barn Swallows and European Pied Flycatchers now winter in the Mediterranean region (Lehikoinen & Sparks 2010).

Distributions of arrival dates under climate change

Databases on arrival (and departure) dates are extensive. For example, Lehikoinen & Sparks (2010) were able to analyse 3827 sets of time series data of first and mean arrival dates for 455 species, ranging in duration from 18 to 53 years. An astonishing 82% showed a tendency for earlier arrival, with significant effects of species and geographical region (Figure 18). The latter effects imply that the advancement in arrival date was consistent for different populations of the same species, but also that different countries have experienced different levels of climate change and hence different degrees of advancement of arrival. The average trend was for earlier arrival by 0·28 days per year for first arrivals, and 0·18 days per year for mean arrivals.

Such results and conclusions rest on a number of assumptions that may cause smaller or larger degrees of bias (Lehikoinen *et al.* 2004, Lehikoinen & Sparks 2010). In order to obtain distributions of arrival and departure dates, information about the actual arrival (and departure) dates on the breeding grounds is ideally required. Thus daily (or less regular) data on arrival must be collected from individuals of known identity (i.e. ringed individuals). There are very few long-term datasets of such accuracy for birds of known breeding origin, and these are restricted to studies of Barn

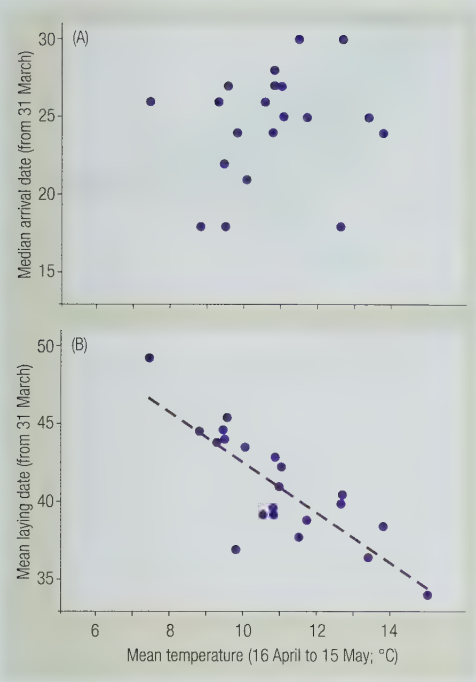

Figure 17

Swallows and a few other species. Most time series of arrival dates are rather based on observations or captures of birds on migratory passage at bird ringing stations, but these data pose many problems. They may be affected by variation in sampling effort among years, as well as by changes in population size. First arrival dates, in particular, will become artificially delayed in decreasing populations (Miller-Rushing *et al.* 2008). If migrating birds are not close to their actual breeding sites, samples of arriving individuals may be biased because more than one population may contribute to the sample recorded. Moreover, changing weather conditions can affect the frequency, timing and duration of stopover during migration, and such changes can affect not only the kinds of birds recorded or captured but also the frequency with which migrating birds land at ringing stations and hence have a probability of being captured. There are additional problems when comparing samples from different years, and when comparing spring and autumn migration, because any of the factors just mentioned (e.g. change in population size, uncertainty about breeding origin of migrants, effects of weather) may change in response to climate change. Using observations collected by amateur birdwatchers may introduce even more bias, for example owing to higher intensity of observations during weekends, or owing to observer activity increasing over time (Sparks *et al.* 2008).

Ideally, the entire distribution of arrival (or departure) should be recorded in order to provide the best information on timing of migration (Sparks *et al.* 2005). Not surprisingly, as noted above, there are only a handful of such studies involving individuals of known breeding origin for a sufficient number of years to allow meaningful analyses. Møller (1994b, 2008a) analysed the distributions of arrival date for Barn Swallows over 32 years, using four key measures obtainable from statistical frequency distributions: mean, variance, skewness and kurtosis ("peakedness" of the distribution). These four measures, which all changed during the study, were related to environmental conditions in North Africa during spring migration as reflected by the Normalized Difference Vegetation Index (a measure of live green vegetation coverage obtainable from satellite data). During benign years when survival was high, mean arrival dates were delayed, showed increased variance, showed decreased skewness, and showed increased kurtosis. This shows that when conditions are better in Africa, not only do Barn Swallows arrive earlier, but weaker selection from mortality on passage lets through birds with a wider range of individual quality: for example, under favourable conditions, poor quality birds survive and arrive later than the smaller number of survivors in normal years. Moreover, arrival time was independently affected by spring temperature on the breeding grounds, with mean arrival being earlier, the variance smaller and the kurtosis smaller in warm springs. These analyses suggest that different aspects of the arrival distributions change in response not only to climatic conditions en route, but also to weather conditions on arrival on the breeding grounds.

Consistency and geographical variation in arrival date

Given the many difficulties associated with time series data of arrival and departure dates, one might ask whether they nonetheless provide us with any worthwhile biological signals. Several studies have shown that they do. First, Rubolini *et al.* (2007) analysed more than 600 sets of time series data with a minimum span of 15 years, showing an overall advance in arrival date, especially so in first rather than in mean arrival dates. Importantly, different species varied significantly in advancement of arrival date, showing that while some species have responded to climate change, others have not. First arrival dates advanced more strongly at intermediate latitudes in Europe, and arrival dates advanced more for short- than for long-distance migrants. Second, as mentioned above, Lehikoinen & Sparks (2010) showed similar differences among species in advancement of first and median arrival dates for more than 3800 sets of time series data. Thus, we can conclude with confidence (1) that different species vary in their response to climate change, (2) that the mean advancement in arrival date is clear and highly significant, and (3) that geographical patterns of advancement in arrival date follow geographical patterns of climate change, which has been particularly pronounced in central Europe.

Evolution or phenotypic plasticity of arrival date in response to climate change

Despite numerous data being collected over more than 200 years, we still do not know to what extent changes in arrival dates are due to phenotypic plasticity (individuals changing during their lifetimes) or evolution (heritable genetic change) (Pulido & Berthold 2004, Pulido 2007, Sheldon 2010). Extent of migration, migratory direction

and annual timing of migration are all heritable characters that can change rapidly in response to artificial selection, as demonstrated by elegant studies of the Blackcap (*Sylvia atricapilla*). Indeed, date of migratory restlessness by Blackcaps has advanced considerably among nestlings from the wild that were reared in the laboratory (Pulido & Berthold 2004, 2010), implying that even in a constant environment there is a significant advance in timing of migration. We also know that many species have altered their migration strategy during the last hundred years, and even during the last 20 years. However, this does not resolve the question about the evolutionary basis for such changes. Because long-distance migrants live on a different continent during winter, and cannot readily be subject to environmental influences from the breeding range in winter, it has been suggested that their response must be due to micro-evolution (i.e. genetic change) (Jonzén *et al.* 2006). However, to demonstrate convincingly that a change in arrival date is caused by micro-evolution rather than phenotypic plasticity, we need to show that the individual genetic component of arrival date has changed in response to climate change. Such analyses in turn require separating the variation in arrival date into its environmental and genetic components, and evidence that the individual genetic component, the so-called breeding value of the individual, has changed. To achieve this, information on arrival date for a reasonably large pedigree of individuals is needed, with information on parents, offspring and grand-offspring. These requirements are difficult to fulfil because migratory birds generally have long natal dispersal distances, making it difficult to record such genealogical data. When estimates from a meta-analysis showing an average advance in arrival date were converted into rates of evolutionary change, the rates were within the limits of what can be considered possible from genetic change alone (Gienapp *et al.* 2007). However, only the study by Karell *et al.* (2011) on plumage coloration has produced conclusive evidence that climate change effects on birds are due to evolution rather than phenotypic plasticity (Gienapp *et al.* 2008, Sheldon 2010).

Blackcap
Sylvia atricapilla
[Illustration by John Cox]

If genetic information on arrival is difficult to obtain, another approach is to test whether phenotypic plasticity alone can account for the observed changes in phenology. If phenotypic plasticity is the underlying mechanism, we might specifically predict that cross-sectional data (comparing individuals in a given year) and longitudinal data (following individuals throughout their lives) should show similar patterns (Przybylo *et al.* 2000). Saino *et al.* (2004) analysed cohorts of Barn Swallows and their temporal change in arrival date for an Italian population that winters in Central Africa, in relation to winter conditions estimated from the Normalized Difference Vegetation Index. They found that the arrival date of old (but not yearling) Barn Swallows was advanced during springs that followed winters with benign environmental conditions in Africa (Figure 19). These patterns of within-individual variation in arrival date subsequently affected the timing of breeding and offspring production, showing that environmental conditions in Africa have carry-over effects to the breeding season, with consequences for annual reproductive success. Interestingly, extensive analyses of another population of Barn Swallows breeding in Spain and wintering in West Africa provided slightly different results: ecological conditions during migration advanced arrival date, while conditions in the winter quarters delayed arrival date; again, however, phenotypic plasticity was sufficient to account for these effects (Balbontín *et al.* 2009b).

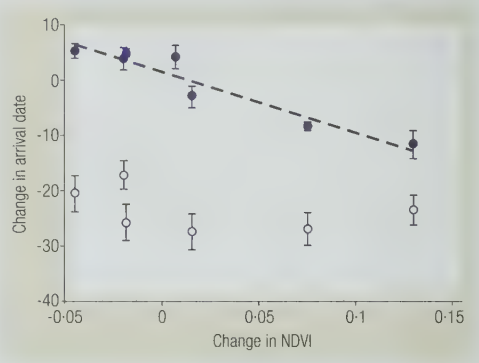

Figure 19
Change in spring arrival by yearling (open symbols) and older (filled symbols) Barn Swallows (Hirundo rustica) *in northern Italy from their Central African winter quarters in relation to change in rainfall in winter as reflected by satellite imaging (NDVI). The line is the linear regression line. Error bars are SE. Adapted from Saino* et al. *(2004).*

Is there any evidence for a role of genetic factors in changes to the timing of migration? To date, the only indication we have comes from an analysis of the genetic basis of arrival date in two populations of Barn Swallows. This showed that spring arrival date was both phenotypically and genetically negatively correlated with morphological traits involved in migration (wing and tail length) and life history traits (time until breeding) (Teplitsky *et al.* 2011). One implication of this finding is that negative genetic correlations may constrain adaptation to climate change, because selection for earlier arrival will necessarily be associated with a delay in breeding.

Breeding vs. winter and stopover effects on arrival date

Changes in arrival dates for migratory birds to the breeding grounds may provide a misleading perspective on climate change if environmental conditions in the winter quarters are in fact the main determinants of timing of migration. However, this is not the only possibility, because early arrival to the winter quarters may allow early moult and hence early departure, as seen in some species (Kok *et al.* 1991, Beaumont *et al.* 2006, Chambers 2008, Møller, Flensted-Jensen & Mardal 2009), but not in others (Møller, Nuttall *et al.* 2011). Therefore, early departure from the winter quarters may in turn be influenced by the timing of autumn migration. Since conditions on the breeding grounds cannot be assessed from the winter quarters, it is difficult for migrants to

adjust their arrival times to conditions at the breeding sites. There is some evidence suggesting that temperature anomalies in Africa affect the arrival date of migrants to the breeding grounds (Saino *et al.* 2007). Investigations of the effects of conditions in the winter quarters on arrival to the breeding grounds have produced mixed results: some studies showed earlier arrival during benign conditions (Saino *et al.* 2004, Gordo & Sanz 2005, Gordo *et al.* 2005, Both, Sanz *et al.* 2006, Møller 2008a), another reported delayed arrival following a benign winter (Balbontín *et al.* 2009b), and another found no effects (Tøttrup *et al.* 2008). Note, however, that only Both, Sanz *et al.* (2006), Møller (2008a), Saino *et al.* (2004) and Balbontín *et al.* (2009b) used breeding populations of known origin, so only these studies are likely to provide reliable tests of how winter conditions affect arrival time to the breeding grounds.

The question is even more complicated by the fact that migrants rest at stopover sites during migration, and that environmental conditions at these sites may affect migration and hence the date of arrival. The frequency of stopover and the time required for refuelling appears to have changed in recent years (Bairlein & Hüppop 2004), and it is known that environmental conditions for both European Pied Flycatchers and Barn Swallows in North Africa during spring stopover affect their arrival date to the breeding grounds (Both, Sanz *et al.* 2006, Møller 2008a, Both 2010a). Furthermore, weather conditions on migration also affect arrival date, especially as migrants approach their breeding destinations, perhaps because migrants at these locations are better able to adjust their migration activity to prevailing weather in large areas in northern Europe (Ahola *et al.* 2004, Tøttrup *et al.* 2008). These data suggest that the annual schedule of migration is determined by environmental conditions in all geographical areas encountered throughout the annual cycle, rather than pinpointing changes in migration schedules to events in a particular area during a specific period.

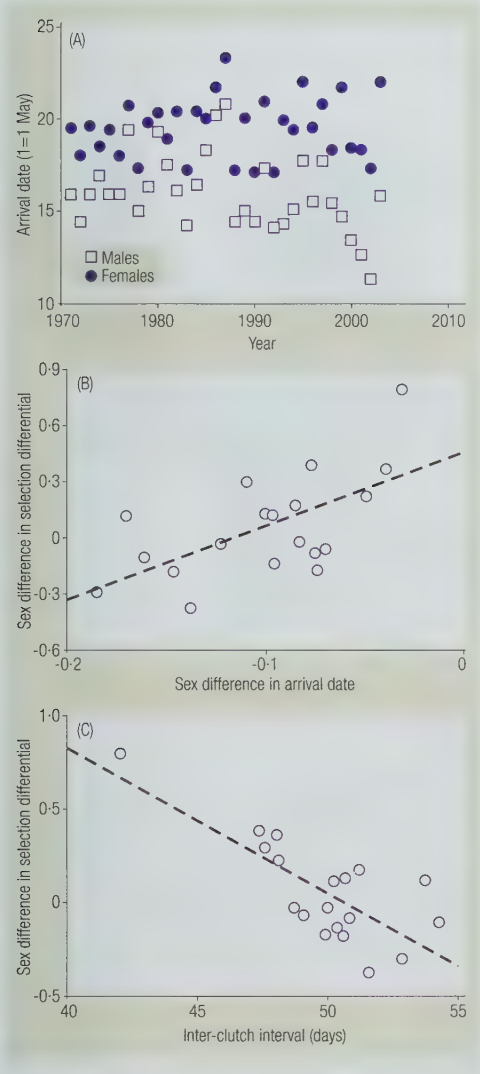

Figure 20
(A) Timing of arrival by male and female Barn Swallows (Hirundo rustica) *in Denmark. (B) The selective advantage of early arrival differed between males and females and changed over time. (C) This sex difference in selection was mediated by an increase in the interval between laying of first and second clutches. The lines are the linear regression lines.*
Adapted from Møller (2007b).

Timing and duration of autumn migration

There are many fewer data on departure dates from the breeding grounds than there are for arrival dates. Lehikoinen & Sparks (2010) analysed 683 time series datasets for 246 species, including 374 last departure dates and 150 median departure dates. A total of 60% of last departure dates became delayed over the study period, while only 36% of median departure dates became delayed. Studies of autumn departure at specific sites show similar trends, at least for long-distance migrants (e.g. Jenni & Kéry 2003). That changes in autumn departure dates should be less clear than those for spring arrival dates is as expected if there has been an advance in the start of reproduction, but little or no change in the end of reproduction. However, some studies suggest that autumn departure is advanced just as spring arrival, at least in single-brooded species with relatively short migrations (e.g. Jenni & Kéry 2003, Van Buskirk *et al.* 2009a).

Sex differences in arrival date and protandry

Bird migration is under intense selection because early-arriving individuals have higher mating and breeding success than later-arriving individuals (e.g. Møller 1994b). Males and females do not benefit equally from early arrival, because competition for high-quality mates is more intense among males, and because tertiary sex ratios (i.e. sex ratios among reproducing adults) are often male-biased, implying that a fraction of males do not mate. Therefore, males should experience stronger selection for early arrival than females, and the fitness benefits males might thus accrue can be quantified. Møller (2007b) analysed the fitness advantages of early arrival in male and female Barn Swallows during a period when spring arrival advanced in a Danish breeding population. Arrival date was quantified by weekly captures of adults at breeding sites, and the fitness advantage was quantified as survival to the next year, as well as by the number of offspring reared during the current year. Males arrived before females, and increasingly so in recent years (Figure 20A). Advancing early arrival was associated with increasingly better survival in males, while females showed the opposite pattern. While early-arriving males survived better and females worse at the start of the study, by the end of the study early-arriving individuals of both sexes survived worse than later-arriving individuals (Figure 20B). Further analyses revealed that this result arose because early-arriving males survived better when inter-clutch intervals were short, while early-arriving females survived better when inter-clutch intervals were long (Figure 20C). Therefore, patterns of selection in the two sexes change in response to advancing arrival dates, leading to a complex result.

The extent of sex difference in arrival date will depend on the cost and benefits of early arrival for males and females. Earlier arrival in males than in females (protandry)

is caused by more intense competition among males (Kokko 1999, Morbey & Ydenberg 2001). In Barn Swallows the degree of protandry (the number of days that the average male arrives before the average female) has increased in recent years because males, responding to warmer springs, arrive earlier, whereas females do not (Møller 2004a). Specifically, the degree of protandry grew as temperatures increased during April, which is when the first birds arrive. In addition, the sex difference in arrival date depended on condition during spring migration in North Africa. Recent years have been characterised by dry weather and resultant poor vegetation quality, as measured by the Normalized Difference Vegetation Index (Møller & Szép 2005). Barn Swallows are at their most vulnerable in North Africa, when they have just crossed the Sahara, and deterioration in environmental conditions here increased the mortality rate, allowing only males in prime condition to survive. Not surprisingly the degree of protandry was larger in years when mainly long-tailed males in prime condition survived; by contrast, in years when even males in poor condition were able to survive, the sexes tended to arrive simultaneously (Møller 2004a).

While these analyses concern protandry at the population level, selection acts at the level of individuals, and any given male may breed with a female that arrives relatively early or relatively late. Does it matter for males if they mate with an early- or late-arriving female? Males that arrived well before their mates gained a fitness advantage because they fertilised more eggs in their own nests than did later-arriving males. The fitness advantage of males mated to females that arrived earlier came from earlier breeding, which allowed their offspring to fledge early and hence have a high probability of survival (Møller, Balbontín *et al.* 2009). These results demonstrate the complexities of selection acting on arrival date when it advances in response to climate change.

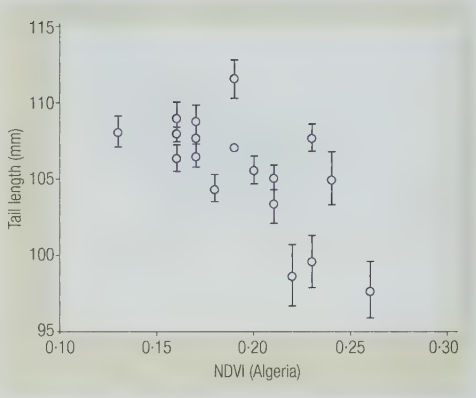

Figure 21
Change in tail length of male Barn Swallows (Hirundo rustica) *in relation to change in rainfall in North Africa during spring migration as reflected by satellite images (NDVI). The error bars are SE. Adapted from Møller & Szép (2005).*

Evolution of secondary sexual characters, colour and body size

Climate change is a forceful selective agent, and it may become even more so in the near future. Characters with high evolvability (i.e. having high genetic diversity on which natural selection can act) should therefore be expected to respond rapidly to climate change. Evidence for this has emerged in several recent studies of secondary sexual characters, coloration and body size, which are all traits that are indeed expected to have high evolvability.

Male Barn Swallows have outermost tail feathers that are on average 20% longer than those of females, and males with long tails enjoy mating advantages in terms of mating success, laying date, annual fecundity and paternity, among others (Møller 1994a). Tail length is also strongly dependent on the individual's condition, so climate change may affect the expression of this secondary sexual character through phenotypic plasticity depending on environmental conditions. Barn Swallows from the Danish population under study winter in southern Africa and migrate across the Sahara through North Africa. As noted above, rainfall has decreased in North Africa since the mid-1980s, resulting in reduced survival mainly of Barn Swallow individuals in poor condition. This change in climate has led to an increase in mean tail length of over 12 mm in males (but not females) at the population level (Figure 21; Møller & Szép 2005). This change in tail length is associated with changing temporal patterns of selection on male tail length due to survival.

A clear example of the effects of climate change on plumage coloration comes from Tawny Owls (*Strix aluco*) in Finland (Karell *et al.* 2011). Tawny Owls occur in two colour morphs that are either brown or grey, as determined by simple Mendelian inheritance with two alleles. There is strong natural selection against the brown morph in winters with lots of snow, when they survive poorly, whereas survival of grey morphs is independent of snow depth. Such snowy winters have become rare, as increasing temperatures have caused snow depth to decline from 12 cm to 2 cm over the period 1981–2008. This has produced a dramatic increase in the frequency of brown morphs, from around 12% in the early 1960s to 42% in 2005–2010 (Figure 22). Thus, climate change has clearly altered natural selection on colour morphs.

Body size of birds is the result of past selection for adaptation to local conditions. Bergmann's Rule states that the body mass of populations of species increases with decreasing mean annual temperature, which is explicable in terms of larger body size reducing the surface-to-volume ratio, and hence minimising loss of energy. We should therefore predict that under climate change, body mass will decline as temperatures rise. The prediction was supported in a study of the size of five bird species in Israel, using body mass and tarsus length of museum specimens for 1950–1999. Body mass and tarsus length were found to have declined in four and two species respectively

Red-billed Gull
Larus scopulinus
[Illustration by Ian Lewington]

(Yom-Tov 2001), and various alternative explanations could not account for these trends. This pattern was further confirmed in a number of breeding bird species in the UK over a period of 40 years (Yom-Tov *et al.* 2006) and in migratory birds in Pennsylvania over a period of 50 years (Van Buskirk *et al.* 2009b). However, no such pattern was found in extensive data on locally hatched juveniles of twelve species of birds in Central Europe (Salewski *et al.* 2010). Thus, while there is evidence for reductions in body size of birds in response to climate change, the findings are not all consistent. It remains to be seen whether these inconsistencies result from differences in sampling, geographical differences in climate change, or other factors. Whether these changes in body size represent phenotypic or genetic changes also remains largely unknown. One study that was able to distinguish the two types of change involved Red-billed Gulls (*Larus scopulinus*) in New Zealand during 1958–2004, and showed a 4% decrease in mean body mass as temperatures increased. In this case the change could be shown to have come about through phenotypic plasticity rather than genetic changes, underscoring the general pattern that commonly observed responses to climate change may arise from plastic adjustments rather than evolution (Teplisky *et al.* 2008). Thus, this example provides evidence than changes in size can be entirely phenotypic rather than genetic.

Climate effects at the population level

Climate change and population dynamics

Emperor Penguin
Aptenodytes forsteri
[Illustration by Francesc Jutglar]

There is little doubt that climate can affect behaviour, reproduction, survival, migration and dispersal of individuals. However, that does not necessarily mean that these individual effects will trickle up to the population level and have an impact on population dynamics. How might climate impact population size? Several alternative mechanisms need careful consideration. For example, climate may have either density-independent or density-dependent effects, depending on whether the fraction of individuals affected by climate is independent of their density (e.g. through extreme weather events causing mortality), or has greatest effect at low and high densities (e.g. through an impact on food availability). We also need to consider whether climate mainly affects reproduction, or mainly survival. Last, we need to consider whether climate mainly affects the mean of demographic values such as population size or reproductive success, or rather their variance. For example, climate may, through its effects on food availability, change mean reproductive success. But as already described, extreme climatic conditions can also dramatically increase the fraction of individuals without reproductive success, thereby increasing the variance in demography among individuals. These alternatives can have significant impacts on expected population responses, as we shall see below.

Population regulation may act during the non-breeding season, either through climatic conditions or through the effects of population density on non-breeding mortality (Lack 1954). Alternatively, populations may rather be regulated by climatic conditions affecting productivity, and hence the number of recruits entering the breeding population. There is an extensive literature analysing effects of weather on population sizes of birds, and a review (Sæther *et al.* 2004) has shown that weather has important consequences for changes in mean demographic variables (such as population size and composition), environmental stochasticity (environmental events affecting the entire population) and demographic stochasticity (variation in demographic parameters among individuals). It also showed that weather has clear effects on density-dependence: northern temperate altricial species such as tits tend to have their populations regulated by winter climatic conditions, whereas it is weather during the breeding season that tends to regulate populations of precocial species such as ducks and partridges.

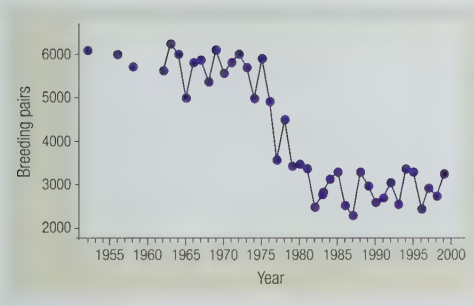

Figure 23
Change in population size of the Emperor Penguin (Aptenodytes forsteri) *in the Antarctic due to changes in ice conditions of the Southern Ocean. Adapted from Barbraud & Weimerskirch (2001).*

The diversity of population responses to climate change is large (Sæther & Engen 2010). Three examples will suffice. The first concerns Emperor Penguins (*Aptenodytes forsteri*), which breed on the Antarctic ice shelf. There has been a dramatic decline in population size of Emperor Penguins associated with a decline in ice cover (Figure 23), with adult survival strongly affected by sea ice conditions and temperature during winter (Barbraud & Weimerskirch 2001, Masson-Delmotte *et al.* 2003, Jenouvrier *et al.* 2005). Because population growth is mainly determined by adult survival, the negative impact of climate change on survival has reduced the population size by half. However, breeding success improved when population size declined, because less competition allowed Emperor Penguins to forage closer to their colonies. Nonetheless, because population size is determined by adult survival, this

improved breeding success has not led at an increase in population size in recent years (Jenouvrier *et al.* 2005, 2009). In contrast to Emperor Penguins, other Antarctic penguin and seabird species have responded differently to these changes in local climatic conditions (Jenouvrier *et al.* 2003, 2005, Forcada *et al.* 2006). This shows that climate change can affect different demographic traits such as reproduction and survival in opposite directions, with complex effects on population size and population growth.

A second example concerns spatial patterns in population dynamics of tits and European Pied Flycatchers. We can understand the spatial dynamics of populations of these species because they have been studied in numerous places for decades. Surprisingly, even neighbouring populations in the Netherlands can show a ten-fold difference in the impact of temperature on local recruitment (Grøtan *et al.* 2009). When analysing the amount of variance in local population dynamics of Great and Common Blue Tits explained by climate, after accounting for density-dependence and demographic stochasticity, there was large variation among populations, even to the extent that climate may affect different populations in different directions (Sæther *et al.* 2007). Some of the variation in the importance of climate is explained by latitude (Sæther *et al.* 2003): while the North Atlantic Oscillation (NAO) only weakly affected dynamics at low latitudes, this effect increased strongly at high latitudes. Among Great Tit populations, NAO explained a larger proportion of the variance in annual size at higher latitudes, while in European Pied Flycatchers there was no latitudinal effect because the proportion of environmental variation in population dynamics also increased with latitude. What mechanism might explain such temporal patterns in effects of climate on population dynamics? One possibility is suggested by the finding that population declines in European Pied Flycatchers in the Netherlands occurred in sites with late food peaks and hence a mistiming between food peak and timing of breeding, while early-breeding populations that did not mistime their reproduction remained stable (Both, Bouwhuis *et al.* 2006).

Population dynamics can be affected not only by processes within a given population, but also by immigration from elsewhere. However, dispersal and immigration rates are generally poorly known. A convincing example of the role of immigration comes from White-throated Dippers (*Cinclus cinclus*), which have experienced population size increases as a consequence of climate change. Cold winters are the main cause of mortality in the species (Sæther *et al.* 2000), and population increases during warm springs are attributable not only to improved success of locally hatched juveniles, but also to higher recruitment of immigrant yearlings from other populations (Figure 24). A surprisingly similar situation has been observed in Great Tit populations in the Netherlands, in which both local recruitment rate and immigration rate were positively affected by environmental variables (Grøtan *et al.* 2009).

Climate change and interspecific competition

Climate change will affect the relative abundance and the composition of different species, through its effects on timing of reproduction and changes in range size. This should in turn lead to changes in the intensity of interspecific competition. A clear example of interspecific competition comes from Dhondt's (1977) classic experiments on tits. These showed that Common Blue Tits consume the early life stages of caterpillars, which therefore never have a chance to grow up and hence become suitable food for the larger Great Tit. More recently, this interspecific competition for food has been shown to be affected by climate, since its intensity varies both among populations and with respect to local climate change (Dhondt 2011).

Climate change can also alter competitive relationships between resident and migratory birds, through its effects on timing of breeding or population density of the competing species. A potential example concerns competition for nest-holes in Europe between resident Great Tits and migratory European Pied Flycatchers that winter in tropical Africa (Ahola *et al.* 2007). Competition arises from individuals of the two species fighting over boxes in limited supply, often with a fatal outcome for one of the individuals. As the interval between laying date of European Pied Flycatchers and Great Tits has decreased due to climate warming advancing the arrival date of European Pied Flycatchers, the number of cases of European Pied Flycatchers dying in the attempt to take over a box of a Great Tit has increased. A higher density of European Pied Flycatchers exacerbated this effect, and the density of each species was respectively determined by climate in Africa for the migrant flycatcher, and climate in Europe for the resident tit.

Both of the foregoing examples provide clear evidence that shifts in the balance of competitive interactions between species are another consequence of climate change.

Climate change and predation

Predators survive by consuming prey, be they krill (*Euphausiacea* sp.) consumed by Emperor Penguins, tipulids by Eurasian Golden Plovers (*Pluvialis apricaria*), herring (*Clupea harengus*) by Atlantic Puffins (*Fratercula arctica*), caterpillars by Great Tits, or Great Tits by Eurasian Sparrowhawks. This diversity of predator-prey interactions can be affected by climate change in direct and indirect ways, and with significant consequences for populations and communities (Bretagnolle & Gillis 2010). The relationship between the abundance of prey and their predators depends both on the functional response (reflecting how the abundance of prey changes in response to consumption by predators), and the numerical response (changes in abundance of predators as a consequence of prey being consumed by and thus converted into predators). Both these responses can be affected directly and indirectly by climate change. The main factors involved are changes in (1) the distribution of prey and predator, (2) the phenology of prey and predator, (3) the population density of prey and predator, and (4) changes in behaviour of prey and predator.

The evidence to date for these four factors is as follows. First, changes in the distribution (in both space and time) of prey and predators may occur as a consequence of one or both parties responding differently to climate change, for example owing to different feeding ecology. Brommer & Møller (2010) showed that insectivorous birds, and in particular terrestrial herbivorous birds, have expanded their range margins the most under recent climate change; however, there was no evidence for differences in range expansion between birds of prey and insectivorous or granivorous birds. Second, an effect of phenology has been shown by Thackeray *et al.* (2010), who found a stronger phenological response of secondary consumers (predators) than primary consumers (herbivores), implying an increasing degree of phenological mismatch for the former (Visser *et al.* 2004). Even studies of bi-trophic food webs (birds and their predators) or tri-trophic food webs (insects, insect-eating birds and their predators) suggest that predators have responded less than their prey (Nielsen & Møller 2006, Both *et al.* 2009). Third, evidence for an impact of climate change on predator and prey density comes from Pearce-Higgins *et al.*'s (2010) work on Eurasian Golden Plovers, which have been affected by climate change-induced changes in the density of their tipulid prey (Figure 25). Fourth, what is the evidence that climate change could affect predator and prey behaviour? To date no studies appear to exist showing that climate-induced changes in behaviour or morphology of prey or their predators have affected predator-prey interactions. One possible scenario we might predict is that the decrease in body size of many bird species linked to recent climate warming (Yom-Tov 2001, Yom-Tov *et al.* 2006, Van Buskirk *et al.* 2009b) may change the prey species preference of predators.

Irrespective of the mechanism, the effects of climate change on predator-prey interactions are likely to depend on whether predators are specialists on one or a few prey species, or generalists consuming a wide variety of prey. Generalists should be relatively unaffected by climate change, because they can switch from one prey species to another if any of their main prey species changes in abundance. However, such prey switches are then likely to affect not only competition among different prey species, but also competition among coexisting predator species. Increasing evidence supports such complex ecological interactions responding to climate change. For example, Millon *et al.* (2009) studied Eurasian Sparrowhawks in Denmark, where their main prey species are the Common Blackbird and the Eurasian Skylark (*Alauda arvensis*). An increase in the abundance of blackbirds was followed by an increase in consumption by the sparrowhawk, resulting in a numerical response through increased sparrowhawk population size, which in turn reduced the abundance of the closely related Song Thrush (*Turdus philomelos*) to very low levels. A study of a specialist vole predator showed that climate change had a ten-fold stronger impact on the Eurasian Buzzard (*Buteo buteo*) than on vole abundance (Lehikoinen *et al.* 2009). Interestingly, the Eurasian Buzzard breeding at the northernmost limit of its range in Finland did not benefit from climate change despite increasing winter temperatures that should have advanced breeding, apparently because cold summer temperatures caused reductions in chick productivity and survival. An example of effects of climate on more than a single predator species comes from a study of two specialist predators, the Long-tailed Skua (*Stercorarius longicaudus*) and the Snowy Owl (*Nyctea scandiaca*), which feed almost entirely on nearctic collared lemmings (*Dicrostonyx groenlandicus*). While there were clear fluctuations in predators and prey until 2000, the density of lemmings subsequently remained very low, leading to a complete absence of Snowy Owls, and Long-tailed Skuas are predicted also to experience severe declines (Gilg *et al.* 2009). These effects were hypothesised to have arisen from climate change affecting the abundance of prey and, therefore, the abundance of predators.

Climate change and host-parasite interactions

Parasites and infectious diseases are common causes of mortality in birds, albeit poorly studied ones. One way in which parasitism could be climate-dependent is that parasites that live away from their hosts for some of their life cycle necessarily depend on climatic factors such as temperature and rainfall. Therefore, climate change will affect the timing of emergence of many parasites, and hence also influence which part of the year parasites are active and can use for reproduction (Dawson *et al.* 2005, Hudson *et al.* 2006). Indeed, several bird ectoparasites, such as louseflies now emerge significantly earlier than just a few years ago (Møller 2010). Such advances in date of emergence also apply to ticks, fleas and other ectoparasites, and to vectors of blood parasites such as blackflies and mosquitoes (Merino & Møller 2010, Møller 2010).

Parasites impose fitness costs on their hosts either by using resources that hosts could otherwise have used for themselves, or by inflicting pathological damage. Extensive studies of humans (Guégan *et al.* 2003, Guernier *et al.* 2004) and birds alike (Møller, Arriero *et al.* 2010) have shown that parasites inflict more severe costs on their hosts in the tropics. This latitudinal trend is apparently due to parasites maintaining high population densities throughout the year in warm climates, whereas at high latitudes, severe winters reduce parasite population size and rate of reproduction. In birds, nestling mortality caused by parasites increases from the northern temperate zone to the tropics (Møller, Arriero *et al.* 2010). Regardless of latitude, increasing temperatures could be expected to result in an increase in virulence (i.e. the impact of parasites on the fitness of their hosts), because more parasite generations can fit into a longer growing season, resulting in an increased rate of parasite evolution. If so, then we should expect virulence to increase with global warming. Effects of increased virulence could be worsened if climate change negatively affects the condition or the nutritional status of the host, thus weakening their immune responses. Recent evidence for rapid changes in virulence came from a study of Barn Swallows, which experienced (by contrast) decreasing per capita costs of parasitism from tropical fowl mites (*Ornithonyssus bursa*) (Møller 2010) over a period of 30 years. Moreover, parasites can also have particularly negative effects on their hosts during adverse environmental conditions (de Lope *et al.* 1993, Merino & Potti 1996). This may help explain how parasites interact with climate to synchronise changes in population numbers of Rock Ptarmigan (*Lagopus mutus*) across different geographical locations in the United Kingdom (Cattadori *et al.* 2005).

Studies of bird parasitism under climate change are particularly important because avian parasites such as those causing malaria and avian influenza may also have implications for human public health. Two recent studies have shown a rapid increase in the proportion of bird hosts infected with malaria and other blood parasites (Møller 2010, Garamszegi 2011). First, two species of blood parasites of the genera *Haemoproteus* and *Leucocytozoon* in the Barn Swallow more than doubled in abundance over a period of 20 years (Møller 2010). Second, an analysis of all studies of blood parasites in birds similarly revealed a strong temporal trend towards increasing prevalence of blood parasites, especially after 1990, when climate change started in earnest (Garamszegi 2011). These findings, albeit preliminary, suggest that blood parasites may increase in abundance with potentially negative impacts on their hosts. Blood parasites have already had significant negative impact on endemic bird populations in Hawaii and New Zealand, and climate change may allow mosquito vectors to move to higher altitudes, reducing the remaining populations of endemic birds that are currently surviving in forest remnants at high altitudes (Benning *et al.* 2002, Tompkins & Gleeson 2006).

The Common Cuckoo (*Cuculus canorus*) and its hosts provide a particularly illuminating example of the effects of climate change on parasites. Arrival dates of long-distance and short-distance hosts have advanced at different rates, with short-distance migrants advancing on average by 0·38 days per year and long-distance migrants by 0·16 days per year (Saino *et al.* 2009). Because the cuckoo is also a long-distance migrant, it has only advanced its arrival date by 0·13 days per year, thus becoming increasingly mistimed with its short-distance migratory hosts. In countries with no change in spring temperature, cuckoos used short-distance migratory hosts in about 80% of parasitized nests, but in countries with the strongest increase in spring temperature, this declined dramatically to only 5% of parasitized nests (Figure 26; Møller, Saino *et al.* 2011). If analysed in terms of change in use of short-distance migratory hosts in relation to their previous levels, countries with no change in spring temperature were predicted to experience an increase in frequency of short-distance migrant hosts by 20%, while the frequency of short-distance migrant hosts in countries with the greatest increase in spring temperature would decrease by an astonishing 60% (Møller, Saino *et al.* 2011). Cuckoos have host races (also often known as "gentes")

Common Cuckoo

Adapted from Møller, Saino et al. *2011.*

specialised to exploiting different host species by mimicking their eggs in terms of colour and volume. The above findings suggest that host races that rely on short-distance migrants such as Meadow Pipits (*Anthus pratensis*), Northern Wrens (*Troglodytes troglodytes*) and European Robins may decrease radically in abundance and ultimately go extinct. This is serious because host races such as those exploiting Common Redstarts (*Phoenicurus phoenicurus*) differ by more than 2% between northern and southern populations, clearly comprising evolutionary important cryptic genetic diversity that exceeds the levels generally considered to reflect divergence at the species level (Johnsen *et al.* 2010).

Climate change may not only affect parasites, but also the ability of their hosts to defend themselves by means of immune responses. Components of the immune system depend strongly on the condition of the host, and any deterioration in climatic conditions can have severe negative effects on the ability of birds to produce an immune response. Indeed, size of the spleen and cell-mediated immunity are reduced in years with adverse weather conditions (Møller & Erritzøe 2003, Merino & Møller 2010), although at present we have no long-term data on immunity in relation to global climate change.

Climate change and extinction risk

The vulnerability of bird populations and their ultimate risk of extinction may depend on climate change. Many ecologists have addressed questions about the extinction risk of populations, trying to provide reliable answers for decision-makers. Most recently Sæther *et al.* (2005) used data on the probability of individuals being recruited into the population to quantify extinction risk for different species. Environmental stochasticity (environmental events affecting the whole population, such as climate change) had the strongest immediate effect on the risk of extinction in birds, while long-term population persistence was most strongly affected by population growth rate. Species with smaller clutches were predicted to have the longest persistence, because stochastic effects on population dynamics were less severe in species with small clutches. Modelling exercises disregarding such stochastic effects have suggested that a large proportion of species may run the risk of extinction (Thomas *et al.* 2004), although the reliability of these projections remains poorly known. Extinction caused by climate change or other factors has important consequences beyond the species involved, since extinction processes may affect wider ecosystem processes (Sekercioglu *et al.* 2004). Even species that are currently common may become extinction prone in the near future, with significant consequences for ecosystem processes such as decomposition, pollination and dispersal of seeds. Two recent studies highlighted the immediacy of potential climate-induced extinction. First, Sekercioglu *et al.* (2008) suggested that a large percentage of bird species inhabiting high altitudes in mountain ranges may risk going extinct as the weather changes and plant communities move upslope. Second, Huntley *et al.* (2010) judged that the risk of extinction among South African birds is greater than previously thought. However, such predictions are fraught with uncertainty because many factors other than climate will affect future distributions of species, making it difficult to assign causality to different potential drivers of extinction (e.g. Vallecillo *et al.* 2009). Moreover, extinction risks entirely based on climate variables and climate change may be exacerbated by other environmental drivers of extinction such as changes in land-use (Brook *et al.* 2008). When making predictions about extinction risks it is crucial to take account of these uncertainties, although this is frequently left aside (Thuiller *et al.* 2004).

With time, real data may come to exist to validate such theoretical predictions about extinction risk. It will certainly be very valuable to closely track changes in population sizes, but in particular to confront such changes with predictions, as environmental conditions enter a phase that has never been seen before in recent history.

Range expansion

Projected changes in distributions and range margins

Future projections of the distribution of species rely either on population viability analysis, which requires very detailed information on demography and population dynamics, or on habitat suitability modelling, which uses information on current distribution to predict the extent of the geographic area that in the future might be occupied by the species. Habitat suitability modelling relies on the observation that climatic

conditions or other factors often predict current distribution ranges quite well, and therefore that we should be able to forecast potential future distributions based on our knowledge of current distributions and future climatic scenarios (Thuiller & Münkemüller 2010). There are many different types of models with their own advantages and limitations, and deviations from assumptions may have large effects on forecasts. One commonly used way to reduce the risk of drawing false conclusions is to use ensembles of climate scenarios—the list of climate change scenarios provided by the IPCC (Anon. 2007c)—rather than a single scenario, when predicting the future distributions of species (Araújo & New 2007).

It is possible to validate the forecasts of such models, and this is often done. One possibility is to test the performance of the model across space or time, for example by comparing predictions with observed population trends, or using retrospective data from the past to project them to current conditions (e.g. Peterson 2003, Araújo *et al.* 2005, Hijmans & Graham 2006, Gregory *et al.* 2009). A slightly different approach is to test a climate-driven model by removing the effects of potential confounding variables one at a time because the effect of each variable can then be partitioned. For example, Vallecillo *et al.* (2009) analysed the effectiveness of a model of bird distribution in relation to land-use change by testing it against another dataset with information on climate and topography as well as land-use. They subsequently analysed the efficiency of fires to predict local colonisation and extinction, showing that exclusion of such important variables as fire can dramatically change the predictions. Hockey *et al.* (2011) provided similar conclusions for South Africa.

Huntley *et al.* (2007) provided the most extensive effort so far to forecast the distribution of the entire European avifauna. This effort based on climate ensemble models provides many interesting insights, but also illustrates how such forecasting sometimes results in extreme situations such as habitats becoming suitable in faraway places like Iceland or Spitsbergen, when in reality dispersal would prevent colonisation of these areas. As well as dispersal, many other factors such as interspecific interactions may prevent such exercises from producing reliable scenarios that can be used in applied contexts such as conservation.

Observed changes in range margins

Ranges of many species of birds have changed during recent decades, as shown by studies in North America, Europe and Africa. In North America, the northernmost range margin of many species is limited by minimum winter temperature limits (Root (1988a,b), and similar patterns are found in Europe (Forsman & Mönkkönen 2003). In South Africa, by contrast, range margins have mainly changed in response to land-use, with little or no direct evidence of effects of climate change (Hockey *et al.* (2011). The north-temperate studies do, however, provide a direct link between climate and distribution, and in these regions we should therefore expect consistent range expansions with increasing temperatures, especially in winter and spring.

The evidence suggests that this is a ubiquitous and common phenomenon (Parmesan & Yohe 2003, Root *et al.* 2003, Hickling *et al.* 2006, Parmesan 2006). Surprisingly, however, published changes in range margins are often modest in magnitude and not statistically significant; this arises from large differences in response among species, with some moving in the "right" and others in the "wrong" direction. One study that did find clear effects was Thomas & Lennon (1999), who used atlas mapping data to show that among breeding birds in the British Isles, those species with southerly distributions advanced their range margins northwards by 1·18 km per year, while species with northerly distributions did not contract their range margins in the south. These estimates were obtained by adjusting for the fact that range margins and population sizes may change simultaneously. This is necessary because it would be unsurprising if a species expanded its range when its population size doubled, but completely surprising if a species expanded its range while simultaneously declining. The latter would provide much more convincing evidence for a role of climate change, making it crucial to control estimates of effects of climate for effects caused by changes in population size and hence dispersal to other parts of the range. Subsequent analyses for Finland showed an even larger advance of 2·69 km per year for southernmost range margins, but again no significant change for northernmost range margins (Brommer 2004). Likewise, analyses of changes in range margins in the US have shown consistent changes in southernmost range margins alone: in the US east of the Rocky Mountains, ranges have advanced by 2·35 km per year east of the Rocky Mountains (Hitch & Leberg 2007), and by 0·64 km per year for New York State (Zuckerberg *et al.* 2009).

These changes all appear relatively modest given the extreme flying ability of most birds, especially their annual migrations of often thousands of kilometres. How-

ever, the foregoing studies all used distributions as mapped by bird atlases; bird censuses, by contrast, may provide superior data for quantifying changes in range margins. Devictor *et al.* (2008) used breeding bird census data from France to estimate a mean shift northwards for the entire breeding bird community of 5·35 km per year, which is considerably larger than the estimates listed above. A possible explanation is that many species in France are close to their southernmost distribution limits, and therefore most susceptible to climate-related effects.

How general are the changes in range margins observed to date? To answer this question, it is useful to know the degree of variation and consistency in the findings of different studies across different regions. Several species were shared between the foregoing four studies of change in range margins, allowing Brommer & Møller (2010) to calculate how consistent findings were among studies. Surprisingly, there was no statistically significant consistency among studies of the same species (Brommer & Møller 2010), implying that if a species shifted north by, say, 10 km per year in the UK, it was unlikely to do the same in Finland. Similar conclusions were reached when controlling for change in range size. These results imply that changes in range margin will depend on idiosyncratic features of local populations, and that it will be very difficult to predict how range margins will respond to climate change.

Even if species are not very consistent in how their range margins change, different categories of species might be broadly consistent, owing to their shared ecological characteristics. Indeed, an analysis of Finnish breeding birds found that groups defined by feeding ecology, migration and habitat were consistent in how their range margins expanded in response to climate change (Brommer 2008). This analysis was subsequently broadened by searching for similar patterns across the four geographical regions listed above (Brommer & Møller 2010). This showed that for Finnish species with a southern distribution, feeding ecology predicted a small fraction of range expansion, especially in seed-eaters and species using aquatic habitats. In contrast, there were no such effects in the UK or the US. Analyses of the Finnish data revealed more change in range margins in insectivores and terrestrial herbivores, as well as in partial and short-distance migrants. Thus there is a certain amount of evidence for the importance of feeding ecology in determining range shifts.

However, other factors could also affect changes in range margins: these might include life history, dispersal distance, thermal range and brain mass (a surrogate for cognitive abilities). To date there is only scant evidence that such traits can predict a species' rate of change: analyses of data from Finland and the UK provided weak evidence that small brain mass was associated with larger range margin expansion, and yet weaker effects of adult survival rate and body mass (Brommer & Møller 2010).

Finally, population trends may have impacts on changes in range margins because an increasing population will produce more emigrants that will disperse elsewhere and thus contribute to range expansion. Brommer & Møller (2010) analysed range margin expansions in relation to population trends in the four studies listed above. There was evidence of a clear positive relationship for species with southern distributions in Finland, the UK and the US, implying that southern species with an increasing population expanded their range margins the most.

Many of the findings reported here suggest that ecological characteristics and population trends are only poor predictors of change in range margins. The majority of studies of change in range margins are based on atlas projects that often have changing definitions of breeding records, and the research effort in each census plot is often inconsistent, albeit with a trend for more effort over time. Thus the data used for range shift analyses may be less than ideal, giving rise to noisy results and conclusions. Clearly the use of extensive breeding bird censuses using standardised methods, as done by Devictor *et al.* (2008), will be the best way forward, especially if estimates for different species can be derived.

Dynamics at range margins

Expansions in range margins are of course made up by the movements of individual birds, but as yet we know very little about whether these individuals differ from the population as a whole. Which are these mobile individuals and what are their characteristics? Are they individuals with extrovert and exploratory personalities? Are they individuals predisposed to be highly dispersive? These questions still need answering.

We can however speculate about which geographical sections of populations are likely to be most affected by climate change. Clearly, some populations at the edges of distributions have changed, as shown by alterations in range margins, but we might further expect that greater fluctuations should occur in populations at the southern compared to the northern margins of a species' range. This is because it is at the south-

ern margins of populations that climate change should generally have been more severe due to increasing temperatures reaching threatening levels, pushing species closer to their extreme limits of heat tolerance. In support of this prediction, as noted above, Brommer & Møller (2010) found stronger evidence for changes in the range margins of species with a southern distribution, and this effect was consistent across studies in Finland, the UK and the US. Models based on future climate change scenarios ("consensus ensemble forecasts") for this century similarly predict that climate change will have particularly strong consequences for the loss of biodiversity in southern Europe, with gains in biodiversity at high altitudes and latitudes (Thuiler *et al.* 2011).

What is the mechanism behind these fluctuations? All organisms have a fundamental niche that reflects the environmental conditions under which they are able to thrive. The actual environmental space a species occupies is partly determined by tolerance to heat and other abiotic factors, and the results described above certainly do imply a link between temperature and population fluctuations, even though birds are homeothermic (body temperature relatively constant). The underlying mechanism relating temperature to population dynamics may be that fluctuations in food availability are greatest at the southern limit of breeding ranges (Pearce-Higgins *et al.* 2010).

Effects at the level of communities

Generalists and specialists

Birds vary enormously in their niche width and hence their degree of specialisation, and this should be expected to influence their susceptibility to climate change. A species' degree of specialisation can be quantified by its distribution across a range of predefined habitats recorded during standard bird censuses such a point counts (Julliard *et al.* 2003). For example, a specialisation index based on 18 habitats in France ranged from a value of 0·23 in the generalist Common Blackbird to 1·16 in the specialist Eurasian Skylark. In this study, specialists were more common in a given locality if the rest of the community was also specialised, and most species reached maximum abundance when the community in which they occurred had a specialisation index similar to their own index. Therefore, as habitats become degraded, habitat generalists come to predominate, and the overall level of specialisation of the community decreases. In France, specialists have been declining much more since 1990 than generalists, even when controlling statistically for other variables such as climatic requirements and life history, and this decline was probably caused by habitat degradation (Jiguet *et al.* 2007). This makes sense since most communities in environments influenced by humans are to a large extent composed of generalists, while specialists, owing to their peculiar habitat requirements, are poorly adapted to changing environments. Taken together, these results suggest that specialist species will be the most severely affected by climate change and consequent habitat degradation and domination of generalist species.

Impoverished communities

Climate change may affect different populations or species in different ways, with consequences for the composition of communities of birds (Stralberg *et al.* 2009). Extensive modelling has suggested that species richness may decline as a consequence of climate change (Huntley *et al.* 2007, Jetz *et al.* 2007). Changes in distribution of species derived from the European climatic bird atlas (Huntley *et al.* 2007) were used by Gregory *et al.* (2009) to predict large-scale patterns of population change for birds in Europe, and these predictions were subsequently tested against observed population trends of species with expanding and shrinking breeding ranges. The results showed that population trends of species benefiting from climate change and species suffering from climate change have grown increasingly more different over the last 20 years, again suggesting substantial climate-induced changes in community composition. In a similar vein, Pounds *et al.* (1999) reported strong declines in species richness for Monteverde in Costa Rica, in this case owing to reduced dry-season mist causing changes in altitudinal limits of montane specialist birds.

The thermal range of individual species will clearly affect such changes in community structure, but those species worst affected may be most likely to come from groups with particular food sources or life histories (Devictor *et al.* 2008). Climate change may particularly impact long-distance migrants that are generally insectivorous, through its effects on the abundance and diversity of invertebrates. Such pre-

dicted changes in communities can be confronted with observed changes in an attempt to test how well actual observations fit predictions. Lemoine *et al.* (2007) and Lemoine & Böhning-Gaese (2003) showed a declining abundance of migrants in the Lake Constance area as predicted from spatial variation in abundance across Europe, providing one of the few examples where observed community composition has been found to reflect the prediction, even when considering several other possible explanations for a decline in abundance of migrants.

Conservation implications of climate change

Which are the species that are particularly susceptible to climate change?

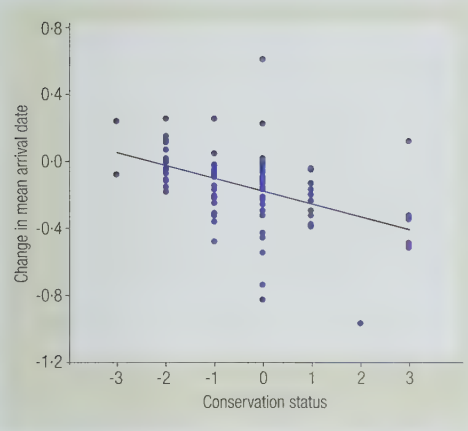

Figure 27
Change in arrival date (days per year) in relation to conservation status of European bird species. The line is the linear regression line.
Adapted from Møller et al. *(2008).*

Climate change clearly has important implications for conservation, given the expected (or indeed already observed) effects of climate change on population declines and risk of extinction. This is starkly illustrated by the finding that species that have failed to respond to climate change are precisely those that have shown the strongest recent declines in population size (Figure 27; Møller *et al.* 2008). These declines were specifically recent ones, subsequent to 1990, which is when climate change started to become most severe. This is strong evidence that it is specifically these species' absence of response to climate change that is responsible for their decline, rather than some other factor. Other possible factors that are commonly related to population declines in birds include habitat use (such as whether species occur in agricultural landscapes), the northernmost limit of a species' breeding ranges, and its body size, but none of these detracted from the climate change effect in Møller *et al.*'s (2008) study. We can take this analysis one step further by considering whether species that have shown such effects have any shared characteristics that put them at particular risk, such as use of agricultural habitats and long-distance migration.

Agricultural intensification is thought to be responsible for declines in abundance of temperate birds living in agricultural habitats (Fuller *et al.* 1995). However, very few studies have investigated the combined effects of climate change and agriculture on population trends of birds. Møller *et al.* (2008) showed a significant negative effect of agriculture for the period 1970–1990, but not after 1990 when response to climate change became the main statistical predictor of population trends. This is as expected because agricultural intensification was particularly strong during the first period (Fuller *et al.* 1995, Burfield & van Bommel 2004), although an alternative interpretation is that agricultural modification of bird populations during that period may have reduced populations so much that no further changes have happened.

Long-distance migratory birds have shown dramatic declines in recent years (Sanderson *et al.* 2006), but since long-distance migrants have also shown weaker responses to climate change (Lehikoinen *et al.* 2004, Lehikoinen & Sparks 2010, Végvári *et al.* 2010), it is interesting to try to partition the role of climate change from the role of other factors affecting population declines of long-distance migrants. This can be done by considering the two simultaneously in the same statistical model, which revealed that declines in populations of long-distance migratory birds were actually relatively weak when the response to climate change is taken into account (Møller *et al.* 2008). This suggests that climate change is the key factor. A study from the Netherlands also emphasised the role of climate over migration per se: long-distance migrants in forests declined more than those in marshes, owing to a stronger effect of climate on the seasonal food peak in forests than in marshes (Both *et al.* 2010). Further correlational support for an effect of climate was the fact that population declines were the strongest in Western Europe, where spring temperatures have increased the most.

A final factor that seems likely to affect a species' susceptibility to climate change is the latitudinal range of its distribution. Indeed, bird species with a northerly breeding distribution have shown greater population declines than species with a more southerly distribution (Julliard *et al.* 2003). More northerly species may be more susceptible to climate change owing to the greater negative effects of climate change on biological diversity (which may include, for example, their food supplies) at northern latitudes (Parmesan & Yohe 2003).

In order to improve our future understanding of the factors affecting the susceptibility of different species to climate change, it is important to consider how best to monitor the consequences of climate change for bird populations. The efficiency of bird monitoring programmes as means of studying bird populations has been analysed by relating interspecific variation in population trends (as assessed by monitoring programmes) to changes in potential breeding range between the late 20th and late 21st centuries, as forecasted by climate envelope models (Gregory *et al.* 2009). Spe-

cies that were predicted to increase the size of their breeding range increased in population size as shown by the European bird monitoring programme, whereas species predicted to decline in range size decreased in population size. Moreover, an index of the impact of climate change on overall trends in bird populations also increased rapidly during the last 20 years, when climate changed particularly rapidly. These findings are encouraging in the sense that they suggest that existing monitoring programmes are capturing biologically meaningful data on population trends. However, the recent acceleration in population declines, coinciding with the worsening of recent climate change, needs careful examination to tease apart the effects of climate change from those of other potentially confounding or interacting factors. This is because numerous other factors have also increased in severity during the last two decades, including intensification of agriculture, forestry and fisheries, and increased urbanisation and pollution. Indeed, two studies of seabirds have shown that significant interactions exist between the effects of climate change and other factors including fisheries (Barbraud *et al.* 2008) and agriculture (Møller *et al.* 2007). Given how many threats to the viability of bird populations have increased in the last 20 years just as climate has, caution needs to be taken in interpreting indices such as that described above. Ideally, an index of the impact of climate change should be developed that statistically controls for other potentially confounding drivers of population declines such as those listed above.

A partial attempt at disentangling these multiple confounding factors was made in a study of 61 species of rare breeding birds in the UK (Green *et al.* 2008). Population trends were correlated with trends in climate suitability (as estimated by climate envelope models), and this effect was shown to be statistically independent of several possibly confounding factors including proximity to the European breeding range, body mass, migration and habitat. However, several other variables that are well established to be important drivers of population trends in breeding birds (such as agriculture, forestry, fisheries, urbanisation and pollution) were unfortunately not investigated.

Overall, the relative role of climate change and other possible drivers of global change for bird populations is a major concern. Only a small minority of studies has considered both categories of drivers, so we know virtually nothing about their relative importance. One such study, by Jetz *et al.* (2007), analysed the relative impact of climate change and land-use change on global diversity of birds using the Millennium Ecosystem Assessment scenarios. Even under relatively benign environmental scenarios (taking into account both climate and land-use change), a staggering 400 species are projected to suffer a reduction in range by more than half by 2050, and no fewer than 900 by 2100. However, these dramatic predictions mainly arose from the effects of land-use change, with climate change having a substantial effect mainly at high latitudes. The species in danger of range loss are mainly endemics with narrow ranges in the tropics. However, these analyses may be considered overly optimistic because the geographic ranges of species were assumed to remain stationary over time, whereas in reality range margins are likely to shift owing to climate change. Likewise, the assumption that all bird species will have sufficient time to adapt to climate change seems particularly optimistic given the strong negative relationship between threat status and response to climate change (Møller *et al.* 2007).

These modelling uncertainties imply that we need to look for empirical evidence to assess the issue. Clavero *et al.* (2011) analysed whether climate change indicators can be influenced by changes in land-use that are in fact not directly driven by climate change. They did so by simultaneously examining how strongly indicators of climate change were related to land-use (with respect to land abandonment, fire and urbanisation) as well as to temperature. Surprisingly, the three land-use indices had as strong an impact on indicators of climate change as temperature. This means that changes in land-use can reverse, hide or even exacerbate apparent impacts of climate change if not controlled statistically. Clearly, many studies have been overly naïve by considering that a correlation between a single climate variable and a biological phenomenon would reflect a causal effect of climate alone, when in fact many other temporally varying factors may play an equally important role. These results call for caution in interpreting models that project changes in the abundance or distribution of species based on climate change alone, since they may not prove to be informative in identifying the most crucial conservation issues facing bird populations.

What can we do to mitigate the effects of climate change?

Given the grim outlook imposed by climate change exacerbated by the effects of numerous other global changes, what can we do to reduce the negative impact of climate

change on bird populations? The first objective must be to do rigorous and thorough research to identify the problems. Many amateurs have collected particularly valuable data in the form of ringing records of individual breeding birds over very long periods. Recently I made a compilation of such long-term studies of individually identifiable birds, which showed that there have been more than 200 such studies covering a time period of more than ten years. This is more than the number of comparably long-term studies of all other kinds of animals combined. Many of the studies reviewed in this essay have used such data, through collaborations between amateur and professional biologists. This emphasizes how such data are extremely valuable for analysing the effects of climate change, as well as for addressing many other fundamental scientific questions. There is scope for many more such studies.

Numerous amateurs and professionals contribute to national bird census programmes, one of the objectives of which is to study the effects of climate change on bird populations. Such long-term schemes are extremely valuable for monitoring populations and for generating information on the factors that constitute threats to birds, and therefore to numerous other kinds of animals and plants. There are many fewer such detailed population studies or monitoring programmes in the tropics and the southern hemisphere, and this lack of knowledge is a major obstacle to our efforts to assess and tackle problems of climate change.

There is no time for complacency, because there is a sizeable community of climate change sceptics who only wait for errors to be made. Too many studies show only a relationship between a biological variable and a single climatic variable, while not considering alternative explanations. Numerous global changes occur simultaneously, and each of these needs careful consideration and analysis. This is crucial to avoid making an open invitation to criticism and reducing the credibility of the scientific community at large.

Conclusions

Birds can be viewed as harbingers of climate change, and they are in a way all canaries in the coal mine of our common environment, experiencing dramatic and sometimes irreversible changes. Numerous other global changes have negative effects on birds and other organisms, and they are likely to interact synergistically with the effects of climate change. These combined threats make it much more difficult for birds to adapt phenotypically and genetically to global change.

A prominent question often raised is as follows: why care about birds when hundreds of millions of humans are starving, and hundreds of additional millions are about to appear into the world? Scientific insights that we learn from birds and other organisms may inform general mitigation of climate change. Climate change will impact on humans, but disproportionately so on poor people in developing countries. There are no simple or easy solutions to the problems created by climate change, because they are a consequence of short-sighted human decisions. We must all act at the personal, community, national and international levels to mitigate and reverse these trends. Only through common and concerted action by many people showing an interest in our common environment will it be possible to reverse the continuing decay of our planet, to the benefit of all living beings alike.

Anders Pape Møller

Introduction to Volume 16

With the present volume we come to the end of our journey through all of the bird families and species in the world. However, HBW does not end here, as we explain below.

Taxonomically, the current volume has in some ways been the most complicated of all, especially in practical terms. The internal arrangements of many families throughout the series have been very complicated, but in this particular volume the complications mushroomed because they stretched across a number of families. The constituent parts of these families have been the subject of disagreement for many decades, but in recent times discussions have come to a head. Numerous studies over recent years, based mainly on molecular analyses, indicate that traditional classifications have treated several groups of species in the wrong families. Although some of these studies were published a good few years ago, most have taken place within the "lifespan" of HBW, and many have been published once most of our Volume 16 authors had already started working on their respective families (some since 1998); in fact, some changes already had implications for families in Volume 15. Although we have been making adjustments to some of the internal family arrangements right up into 2011, it was obvious to us early on that we could not keep chopping and changing the make-up of various families each time a new study was published—nor did we wish to rush into important changes of this sort as soon as they were published, before the ornithological community at large had had time to assess them. Clearly, it was essential for all the authors to know as early as possible which species each was to cover in his respective family—without this base, it was impossible for them even to start their work, and there was still plenty of scope for subsequent tweaking of the internal sequences. A few of the ground-breaking changes from traditional family assignations probably were well enough established to have been taken on board at that time, but we decided that ultimately it would be more confusing for everyone if we adopted just a few of the changes that were being spoken about in the mid-1990s, a sort of half-way house. It is worth noting, too, that some of the ideas that appeared promising around that time have since fallen out of favour.

The long and the short of all this is that we decided that it made most sense to stick to the guiding principles followed in the rest of the series and treat all the various groups and species in their traditional families, where the ornithological public in general would have least difficulty in locating them. As previously stated, HBW's prime purpose is to summarize and present information as a practical reference source, and while many may disagree with various parts of the traditional sequence, at least everybody knows roughly where to start looking for any given taxon. Emberizidae (*sensu lato*) is the only case in the series in which a considerable number of species are covered in what are, from a phylogenetic viewpoint, likely to be the wrong families.

It should be noted that throughout the series, the internal arrangements of families have always been agreed between the authors and editors. In a number of cases, the editors felt that certain proposals by authors were not appropriate for the overall consistency of the series, and we are extremely grateful to all authors over the entire series for kindly and patiently accepting our decisions, and all the shortcomings they may imply. It should also be made quite clear that, again throughout the series, we have done our best to accommodate any preferences expressed by authors regarding English names. However, again for reasons which we think are obvious, the final decisions have been made centrally in the interests of overall consistency throughout the series.

For the last foreword in our series of essays on ornithological themes we felt that one of the most topical subjects of our times could not be overlooked. To this end we decided that we needed a foreword dealing with global warming and its effects on birds. We are delighted to be able to present this essay by one of the subject's leading

researchers, Anders Pape Møller. We think this comprehensive overview brings a fine ending to the series...but wait! There is more to come, as we explain below.

As well as marking the end of the series, this book constitutes the last of the nine passerine volumes. As in the case of the last non-passerine volume, a practical plastic-coated reference card accompanies the volume. This is designed to act as an index to all of the families covered in these nine volumes, enabling readers to locate any of the families in this second part of the series. Different taxonomic views have led to wildly differing sequences, and this is particularly true in the case of the passerines. As a result, even those readers with a good knowledge of avian taxonomy may not always be too sure in which volume a particular group is covered, and it is hoped that the keys on this card will make this task a good deal easier and quicker. To recap on the Introduction to Volume 7 (the last of the non-passerine volumes), there are two ways of using the index. On one side, there is a visual scheme in HBW's taxonomic sequence, in which each passerine family is symbolized by one of its most representative members, followed by the volume and the page number on which the corresponding family section starts. On the other side of the card there is an alphabetical list of the scientific and English names of all of the orders and families covered in Volumes 8-16, as well as the English names of all species groups included in the families.

In addition to these key cards for the non-passerines and passerines, HBW clearly requires a comprehensive index to the entire series, a single source for locating both scientific and English names of all avian taxa dealt with in the series, from subspecies and species up to families and orders, so that a reader interested in any particular taxon can quickly discover on which page of which volume it is to be found. This index to the entire series obviously requires a large number of pages, far too many to add to the current, already-packed volume, so the overall index will appear in a separate, slimmer tome entitled *Special Volume: New Species and Global Index*. As the title suggests, in addition to the overall index, this volume will cover all those species described after the closing dates of their respective volumes. Each of these species will receive a standard HBW species account, along with a disribution map, illustration, and so on. In this way, HBW will ensure that it fulfils its original undertaking to illustrate and cover in detail all the species of birds of the world—with the logical and inevitable exception of those species that still remain to be described to science.

The volume will also include an illustrated chapter covering the notable developments in macrosystematic thinking that have taken place in recent times, discussing current and recent perceptions about the interrelationships of higher taxonomic groups. Much of the recent progress in this field has been made through molecular studies, and a great deal of it has been carried out in the years since HBW began, so this seems a particularly appropriate time for such a summary. Other features that will appear in this Special Volume are still at the planning stage. Full details will be released in due course, both about the contents of this Special Volume and about the various ways in which the HBW project will be maintained constantly up to date online.

Acknowledgements

We are very grateful for the kind assistance received from museums and their helpful staff, and we would like to thank the Natural History Museum at Tring (Robert Prys-Jones, Mark Adams), the American Museum of Natural History in New York (Paul Sweet, Thomas Trombone, Matt Shanley, Mary LeCroy), the Smithsonian Institution, National Museum of Natural History in Washington (James Dean, Christina Gebhard), the Peabody Museum at Yale University (Kristof Zyskowski, Tim White), the Museum of Comparative Zoology at Harvard University (Jeremiah Trimble), the Field Museum in Chicago (David Willard, Mary Hennen, Josh Engel), the Zoological Museum at the University of Copenhagen (Jon Fjeldså, Jan Bolding Kristensen), the North Carolina Museum of Natural Sciences (Douglas Pratt), the Academy of Natural Sciences in Philadelphia (Nate Rice) and the Lousiana State University Museum of Natural Science (Ryan Terrill, Steven Cardiff). We offer our special thanks to the Naturkundliches Universitätsmuseum at the Martin-Luther-University Halle-Wittenberg for the important role it has played in recent volumes, particularly in the support and resources afforded to Frank Steinheimer for HBW work.

For assistance in the preparation of the bibliographies we would like to thank Kevin J. Burns (San Diego State University), Paul Cooper (BMNH, General Library, London),

Sarah Sworder (BMNH, Earth Science Library), Alison Harding (BMNH, Ornithological Library, Tring), Martina Rissberger and Hans-Ulrich Raake (General Zoology Library, Museum für Naturkunde Berlin), Pascal Eckhoff (Ornithological Library & Bird Collection, Museum für Naturkunde Berlin), Arnulf Trimms (University Library Göttingen), Mikhail Kalyakin (Zoologicheskii Muzei Moscow), Bill Maynard (*Winging It* Editor, USA), Joaquín Sánchez González (*Brenesia* Editor, Costa Rica), Dietmar Schmidt (*Gefiederte Welt* Editor, Germany), Matthias Perl (Johannes-Gutenberg-University Mainz, Germany), Lars Svensson (Stockholm, Sweden), Per Alström (Swedish University of Agricultural Sciences, Uppsala), Magnus Ullman (Brantevik, Sweden), Hein van Grouw (BMNH, Tring), Ursula Peter (Nuremberg, Germany) and Ekaterina Bräunlich (Berlin, Germany). We consulted the libraries of the ZMB, Halle and Göttingen universities, and the online catalogues of the American Museum of Natural History, New York, and the Natural History Museum, London, and we thank these institutions. Also, for specific help with the scientific descriptions we would like to extend our warm gratitude to Norbert Bahr, Normand David, Edward Dickinson, Bob Dowsett, Michel Gosselin, Steven Gregory and Alan Peterson.

The following individuals gave most kindly of their assistance in a variety of ways, from refereeing texts to providing access to unpublished information and literature, and answering queries. We should like to thank Andreas Buchheim, Bob Dowsett, Françoise Dowsett-Lemaire, Magnus Hellström, Mort Isler, Jirí Mlíkovský, Nial Moores, Scott Olmstead, Marco A. Rego, Gary Ritchison, Luís Fábio Silveira, Gary Stiles, Kirsten van der Veen and Daria Wingreen-Mason. For particular help related to the plates and photographs, we should like to thank Hilary Burn, Steve Hilty, Arnau Jutglar, Mònica Puig and Robin Restall. We are especially grateful to Claire Spottiswoode, Nigel Collar and Alvaro Jaramillo for their special editing assistance with the volume.

We also warmly thank Robert Ridgely for his continuing important revision of the individual maps affecting the Neotropics. We greatly appreciate the considerable time and effort dedicated by Normand David and Michel Gosselin in their checking all the genus- and species-level taxa for gender agreement, correct spelling and various other details. We also send special thanks to Normand, Michel and Edward Dickinson for assisting us with many important consultations on scientific names, their original descriptions, accurate dates, and a wide variety of other important matters. And once again, we would like to express our gratitude to Guy Tudor and Michelle le Marchant for supporting the entire HBW series by making available Guy's large collection of reference material.

In dealing with all matters involving the French, German and Spanish names we are very grateful to Normand David, Michel Gosselin, Peter Barthel, Einhard Bezzel, Renate van den Elzen, Christoph Hinkelmann, Frank Steinheimer and Eduardo de Juana, together with their respective associates.

The individual authors and artists of the volume would like to thank Casiana Ahumada, Hans Altner, Mauricio Álvarez Rebolledo, David Anderson, Wayne Arendt, Juan Ignacio Areta, María M. Argel, David Ascanio Echeverría, Diana Balcázar Niño, Bob Bates, John Bates, Ernst Bauernfeind, John Beaumont, Marcelo Bettinelli, Alejandro Bodrati, Carlos Bosque, Kimberly Bostwick, Frederik Brammer, Walter Braun, Juli Broggi, Kevin J. Class AVES

Order PASSERIFORMES

Suborder OSCINES

Family THRAUPIDAE (TANAGERS)

- Small to medium-sized passerines with medium-length wings, tail, legs and feet; plumage soft, or dense and plush-like; many species colourful, often with complex plumage patterns.
- 9–29 cm.

- Middle and South America, Caribbean, and marginally North America.
- Humid forest, light woodland, borders and shrubby savanna, rarely marshes, open savanna, shrub-desert and xeric scrub.
- 64 genera; 283 species; 788 taxa.
- 23 species threatened; none extinct since 1600.

Systematics

In 1969, an article by R. W. Storer entitled "What is a Tanager?" was published in the journal *The Living Bird*. In his opening paragraph Storer cited a statement written in 1886 by P. L. Sclater, who, while publishing a catalogue of tanagers, wrote the following: "In essential structure the Tanagers are closely allied to the Finches, and it is in any cases exceedingly difficult, if not impossible, to draw a line between the two groups... On the other hand, some of the tanagers have also nearly equally close relations with the Mniotiltidae [Parulidae] and the Coerebidae; and I do not think it is at present practicable to give any absolute characters which would serve to differentiate the birds of these three families in all cases." Storer then added: "Today, Sclater's statement is as valid as it was eighty-three years ago."

Storer, like his predecessor Sclater, groped for solutions, anything morphological or behavioural, or vocal that would unite this uneasy assemblage of birds. Lacking the analytical tools of modern DNA analysis, which would not be developed until two or three decades later, he ultimately made little real progress in furthering an understanding of the limits of the group of birds known as tanagers. Although many ornithologists suspected that tanagers were an artificially erected group with numerous genera that were unrelated to one another, it would be almost thirty more years, following the advent of modern DNA-sampling, before real progress would be made in defining the group. Among the first of these, in the 1990s, were the DNA–DNA hybridization studies of three "coerebid" genera, *Coereba*, *Diglossa* and *Cyanerpes*, by C. G. Sibley and J. E. Ahlquist, who concluded that all three belonged in the tribe Thraupini, which included a large number of tanagers and finches. More recently, using DNA-sequence data, K. J. Burns and a number of other researchers have begun to piece together an entirely new picture of tanager relationships, and some of their findings, and those of others, were startling. Important genera within the family, some that had been heralded as "classic tanagers", and so-called archetypical members of the family, failed their DNA tests. Investigations continue, but there now is strong evidence that about 20–25% of the genera traditionally regarded as tanagers are more closely related to other groups of birds than they are to "typical" tanagers. Moreover, the molecular-genetic analyses indicated that, classified among the emberizids, cardinalids, and the now completely dismantled family Coerebidae, were at least 30 genera that have proven to be much closer to tanager ancestral lines than to the families in which they have long been placed. Several well-known genera, long believed to be finches, among them *Phrygilus*, *Sicalis*, *Poospiza* and *Sporophila*, also proved genetically closest to thraupids. Further, the entire assemblage of coerebids, including *Coereba*, *Cyanerpes*, *Diglossa*, *Dacnis*, *Conirostrum* and *Chlorophanes*, having in the past been included in Coerebidae or spread among as many as three different families, including Thraupidae, have all been shown to align closely within the thraupids in ways not previously suspected by taxonomists, who had relied upon bill morphology and feeding behaviour as clues for relationships. Research continues to refine the limits of this

Few, if any, morphological features are common to all members of the tanager family, Thraupidae. Attempts to relate diet, bill shape and jaw musculature, and colour, pattern and texture of plumage, have failed to define the family. Some tanagers are small and quick, some large and sluggish; some are thin-billed and warbler-like, some heavy-billed and finch-like. The ***White-banded Tanager*** *bears a striking resemblance to certain shrikes* (Lanius) *of northern-temperate regions, which occupy partly open terrain similar to where this tanager is found.*

[*Neothraupis fasciata*, Das Emas National Park, Goiás, Brazil. Photo: Edson Endrigo]

Molecular-genetic studies have found that several genera previously assigned to other families really belong within Thraupidae, while other genera traditionally included within the tanager family belong elsewhere. For example, recent genetic data indicate that the ***Red-billed Pied Tanager*** *is probably not closely related to other thraupids, but no closely related family or sister-taxon has yet been identified. It is one of only two of the more than 250 species originally placed in the family to sport a brightly coloured bill.*

[*Lamprospiza melanoleuca*, Rio Roosevelt Lodge, Novo Aripuanã, Amazonas, Brazil. Photo: Edson Endrigo]

fascinating group of birds, but future arrangements of the tanager family will probably include 30–40% more species than contained in traditional classifications, and will include species that occupy essentially every major habitat in the New World tropics. As the taxonomic dust settles, one fact is becoming clear, namely that few avian families have been so universally misunderstood taxonomically, or have included so many taxa that have proved to be erroneously classified, as the tanagers and allied cardinalids and emberizids.

In the present treatment, tanagers are regarded as constituting a taxonomic family, Thraupidae. In the past, they have been treated sometimes as a tribe, Thraupini, and sometimes as a subfamily, Thraupinae, and one of these lower taxonomic designations could prevail in the future. Irrespective of ultimate classification, tanagers are part of a massive New World oscine radiation of nine-primaried birds that includes well over 800 species placed in some 200 genera. Historically, these species have been divided into five groups or assemblages, each being designated as a tribe, a subfamily or a family depending upon the classification scheme used. Popular books and lists usually show each of these groups as an individual family, for example Icteridae (New World blackbirds), Parulidae (New World warblers), Emberizidae (buntings and New World sparrows), Thraupidae (tanagers) and Cardinalidae (cardinals). When designated as tribes, the five groups are Icterini, Parulini, Emberizini, Thraupini and Cardinalini. Some checklists, such as the Sibley and B. L. Monroe world list, as well as most molecular-genetic research appearing in scientific publications, treat these groups as subfamilies or tribes. The "true" classification of these avian groups has long been the subject of debate among taxonomists, in addition to which the composition of these five groups, and their relationships to one another, remain unsettled. Unfortunately, comparative studies of external morphology, including jaw musculature, pelvic musculature and serology, cranial and palatal characters, and appendicular myology, have yielded only a few characters useful in defining relationships at the tribe, subfamily or family level, and the interpretation of these results is often controversial. Consequently, studies based on morphological relationships have led to conflicting taxonomies and little consensus. More recent molecular-genetic studies appear to have had better success in sorting out relationships at the macrosystematic levels and, more recently, at the species level as well.

Morphological studies have had greater predictive power when assigning taxa to tribes. For example, Icterini and Parulini possess distinctive bill and body morphologies that tend to be more easily distinguished. Problems arise, however, within Thraupini, Cardinalini and Emberizini. Traditionally, taxa were assigned to Cardinalini on the basis of the presence of a large, thick bill, but certain species of Emberizini and Thraupini also have a large, stout bill, leading some taxonomists to regard the Cardinalini as an artificial group composed of species that are probably either thraupine or emberizine. The taxonomic placement of many species based only on bill shape, which is now known to be one of the most highly labile of all avian characters, has remained controversial.

Significant progress in breaking this taxonomic "log jam" has come mainly since 1990, following the widespread use of

Although many tanagers are among the most colourful of all passerine birds, some are quite plain and modestly patterned. The plumage of the ***Brown Tanager*** *bears a close resemblance to that of the* Philydor *foliage-gleaners. Brown Tanagers are often found in mixed flocks with the very similar-looking Buff-fronted Foliage-gleaner* (P. rufum)*, and it has been suggested that the Brown Tanager has become adapted as a social mimic of this species. Its bill, however, is slightly thicker, swollen-looking and blackish in colour. The Brown Tanager belongs to a monotypic genus that is confined to the humid pre-montane and montane forests of south-eastern Brazil.*

[*Orchesticus abeillei*, Itatiaia City, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Rather like a jay (Corvidae) in appearance and behaviour, the ***White-capped Tanager*** *is one of the largest thraupids. The female is similar to the male, shown here, but her throat and chest are a darker, duskier and less conspicuous crimson. Despite numerous earlier suggestions to the contrary, morphological and genetic data support placement of this species within Thraupidae. The White-capped Tanager belongs to the monotypic genus* Sericossypha*; molecular-genetic studies suggest that this genus and the tanagers of the genus* Nemosia*, such as the Hooded Tanager* (Nemosia pileata)*, as seen in the next picture, are probably sister-taxa.*

[*Sericossypha albocristata*, Río Blanco, Colombia. Photo: Pete Morris]

molecular studies, and has continued to accelerate to the present day. One of the first molecular studies was the work by Sibley and Ahlquist on DNA–DNA hybridization, which began in the 1970s. For the first time, these authors placed in the tribe Thraupini a group of heavy-billed, finch-like birds that had historically been allocated to Emberizini. Additional work by J. Klicka, T. Yuri and others further refined the taxonomic boundaries of the New World nine-primaried oscines, dividing them into five separate clades, more or less equivalent to five tribes or, as in the present treatment, to five families, including the parulids, cardinalids, thraupids, emberizids and fringillids. Techniques for DNA analysis have continued to undergo refinement, and the mantle of obfuscation surrounding relationships within the tanagers, as well as in allied nine-primaried groups, is finally being stripped away. The ultimate goal, that of defining monophyletic lineages in each of the nine-primaried groups mentioned above, is at last close to being achieved. More than 120 years have passed since Sclater articulated his frustration at attempting to define taxonomic limits for the tanagers on the basis of external morphological characters. Now, a solution seems to be at hand.

In the light of rapidly developing taxonomic changes, one problem has been that of how to present the tanager family and allied groups. In the present handbook, in view of the extensive recent research, it has been considered both inappropriate and impractical, as well as potentially confusing for everyone, to be reshuffling various species from one family to another continually in attempts to reflect the most up-to-date perceptions of accurate taxonomic relationships, not only for the tanagers, but also for other avian families. As is apparent in the summary presented below, numerous genera and species have been traded back and forth among the nine-primaried songbird families, and this rearranging of taxa continues.

Consequently, the present treatment will continue to have a traditional appearance for the family. This conservative approach also avoids the complications of English names rendered inappropriate by the transfer of species with the name "Tanager" to other families and vice versa. This systematics section, however, summarizes recent molecular-genetic studies that now broadly outline a new framework of relationships for the tanagers. The remaining sections of the chapter, on the other hand, deal with species traditionally included within the tanager family, although those species now believed likely to belong elsewhere, such as those in the genera *Chlorophonia*, *Euphonia*, *Chlorospingus*, *Mitrospingus*, *Chlorothraupis*, *Piranga* and *Habia*, are, wherever possible, discussed separately.

Using molecular techniques, scientists have made great strides towards an understanding of thraupid systematics. Of particular importance is the molecular work conducted or directed by Burns, and also of notable value is the work of the following researchers: J. E. Ahlquist, A. H. Bledsoe, E. Bermingham, J. Fjeldså, J. García-Moreno, S. J. Hackett, N. K. Klein, J. Klicka, D. A. Lijtmeir, S. C. Lougheed, I. J. Lovette, W. M. Mauck, D. P. McDonald, D. P. Mindell, K. Naoki, R. A. Racicot, C. Rahbek, A. Sato, G. Seutin, C. G. Sibley, J. D. Webster, J. T. Weir and T. Yuri. The contributions of these scientists have, for the first time, enabled real progress to be made in constructing a comprehensive taxonomic framework for tanagers. Despite the employment of different molecular and analytical techniques, the results of these studies show broad agreement, a fact that lends confidence to these new phylogenies. When the findings of various studies do not agree, the problems often can be traced to insufficient taxon-sampling, which produces incomplete results. Earlier studies often were not sufficiently comprehensive, as too few representatives from a family or genus were examined. In phylogenetic studies, missing taxa can have important effects on the ultimate topological structure of a taxonomic tree.

The outline below summarizes important recent molecular-based taxonomic findings with regard to tanagers. Most of these findings are likely to be reflected in future sequential taxonomies, and these results should be kept in mind when reading subsequent sections of this family text, which are based on an older, traditional taxonomic framework.

First, recent genetic data indicate that the following genera, traditionally placed by most authors in Thraupidae, do not have close relationships to members of this family and almost certainly belong elsewhere, the placement of some remaining uncertain:

1) *Euphonia* and *Chlorophonia* are unrelated to any Thraupidae and should be placed in Fringillidae, perhaps as a subfamily.
2) *Chlorospingus*, together with the Caribbean genera *Spindalis*, *Nesospingus* and *Phaenicophilus*, may form a monophyletic clade sister to some parulid genera, although recent evidence

Although extremely diverse in their plumage colours and patterns, the tanagers are generally rather homogenous in their bare-part colours, horn, grey and blackish predominating. The male ***Hooded Tanager*** *is one of the few members of Thraupidae to have brightly coloured legs. The female's legs are a duller yellow but, in contrast to the male's all-black bill, she has a pale yellowish lower mandible. Both sexes have yellow irides. The congeneric Cherry-throated Tanager* (Nemosia rourei) *also has a yellow iris and pinkish-yellow legs. The iris colour of most tanagers is dark, varying from brown to reddish-brown.*

[*Nemosia pileata caerulea*, Fazenda Cupido, Sooretama, Espírito Santo, Brazil. Photo: Edson Endrigo]

suggests that *Chlorospingus* is closest to the emberizid genus *Arremonops*; none of these genera belongs with Thraupidae.

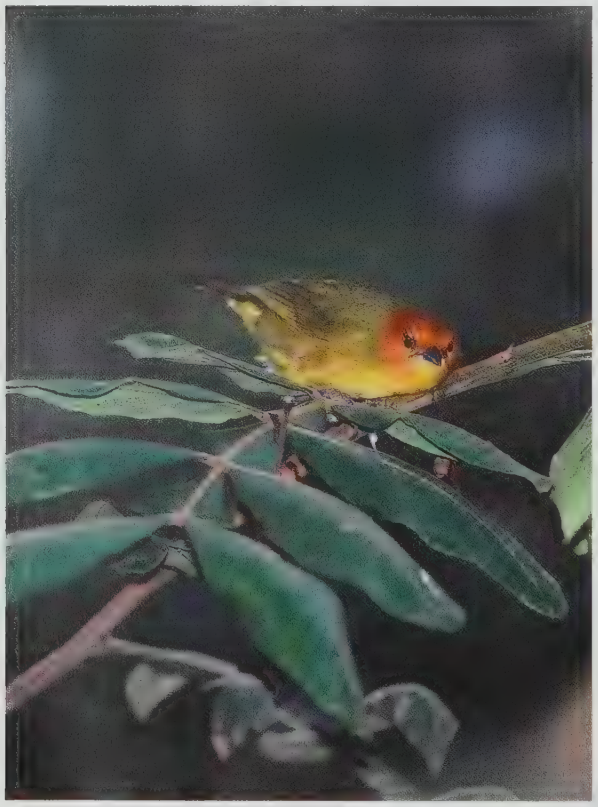
3) *Mitrospingus* should be removed from Thraupidae; its genetic affinities remain uncertain, but are possibly closest to Cardinalidae.
4) *Rhodinocichla*, the enigmatic thrush-tanager, is equivocal in its ancestral relationships; morphological data support its inclusion within Thraupidae, but genetic data reveal weak support for retention within this family.
5) *Piranga* appears now to be embedded within the cardinalids, and to form a well-supported clade with *Habia* and *Chlorothraupis*.
6) *Habia* appears now to be genetically closest to the cardinalids, and the current arrangement of the genus is polyphyletic; the Red-crowned Ant-tanager (*Habia rubica*) is more closely related to members of *Chlorothraupis* than are other *Habia* species, although sampling is still incomplete.
7) *Chlorothraupis* appears genetically closest to the cardinalids, forming a clade with *Piranga* and at least some *Habia*.
8) *Lamprospiza* is currently retained within Thraupidae, although its placement here has been questioned.
9) *Calyptophilus*, containing the two chat-tanagers, almost certainly does not belong in Thraupidae.

The twelve species in the genus Hemispingus *are mostly rather dull-coloured, and mainly restricted to the Andes. Taxonomic relationships within the genus have for long been a source of confusion. The* ***Orange-browed Hemispingus*** *may form a superspecies with the White-browed Hemispingus* (H. auricularis) *and the Black-capped Hemispingus* (H. atropileus), *and has been treated as conspecific with either or both of these. It differs from these species mainly in its broader, orange (rather than whitish) supercilium. The Orange-browed Hemispingus, however, may be most closely related to Parodi's Hemispingus* (H. parodii).

[*Hemispingus calophrys*, Cotapata National Park, La Paz, Bolivia. Photo: Joe Tobias]

Second, molecular-genetic research suggests that a number of genera previously placed variously in one or other of the families Emberizidae, Cardinalidae and Coerebidae, or at times provisionally in Thraupidae, almost certainly do belong in the family Thraupidae:

1) As already mentioned, the historically recognized family Coerebidae is no longer warranted, having been shown to comprise a group of disparate members within a larger radiation of tanagers and finches. *Coereba*, *Conirostrum*, *Oreomanes*, *Diglossa*, *Cyanerpes*, *Dacnis*, *Euneornis*, *Xenodacnis*, *Chlorophanes* and *Iridophanes*, all formerly placed, at various times, in Coerebidae, are now known to be closest to Thraupidae.
2) *Coereba*, previously placed in various families, shares a monophyletic ancestry that includes Galapagos finches and the Caribbean genera *Euneornis*, *Loxigilla*, *Loxipasser*, *Melanospiza* and *Melopyrrha*, all of which align well within the Thraupidae.
3) Galapagos finches of the genera *Certhidea*, *Platyspiza*, *Camarhynchus* and *Geospiza* appear genetically allied to Thraupidae, most closely to *Coereba*, *Tiaris* and several Caribbean genera.
4) *Tiaris* grassquits appear closest to Thraupidae and form part of a monophyletic group with *Coereba*, the Galapagos finches and several Caribbean genera; *Tiaris* itself is probably para-



The genus Cnemoscopus, *of which the* ***Grey-hooded Bush-tanager*** *is currently the sole recognized member, is part of a clade of small tanagers of a mostly Andean radiation that also includes the* Hemispingus *tanagers. The Grey-hooded Bush-tanager has sometimes been placed in* Hemispingus *and is close to this genus in morphology, feeding behaviour and vocalizations. Despite its English name, it frequents forest trees, rather than bushes. The race* chrysogaster, *which differs from the nominate in size, plumage and eye, bill and leg colour, has been treated as a separate species.*

[*Cnemoscopus rubrirostris rubrirostris*, Guango, Ecuador. Photo: Greg & Yvonne Dean/ WorldWildlifeImages.com]

phyletic and has previously been included within Emberizidae and Cardinalidae.

5) *Phrygilus*, a group of high-Andean and Patagonian species, appears now to belong in Thraupidae.
6) *Diuca*, comprising a pair of high-Andean and Patagonian species, is considered to belong in Thraupidae.
7) *Haplospiza*, an odd, bamboo-inhabiting species, is genetically closest to Thraupidae.
8) *Poospiza* mountain-finches of the high Andes are more closely allied to Thraupidae, especially to *Pyrrhocoma*, *Thlypopsis*, *Cypsnagra*, *Nephelornis*, *Hemispingus* and *Cnemoscopus*, than to Emberizidae; the genus *Poospiza*, as currently constituted, may itself not be monophyletic.
9) *Sicalis* yellow-finches are genetically allied with Thraupidae.
10) *Embernagra* pampa-finches almost certainly belong with Thraupidae.
11) *Volatinia*, a monotypic grassquit genus, aligns with Thraupidae and appears most closely related to members of the genus *Conothraupis*.
12) *Sporophila* seedeaters and *Oryzoborus* seed-finches belong with Thraupidae, and the two genera themselves possibly should be merged.
13) *Catamenia* seedeaters of the high Andes belong with Thraupidae and are evidently most closely related to the flowerpiercers (*Diglossa*), a high-Andean dacnis (*Xenodacnis*) and the Central American Peg-billed Finch (*Acanthidops bairdii*), the last currently placed in the family Emberizidae.
14) *Saltatricula*, an Argentinian finch currently included within Emberizidae, is more closely related to the Thraupidae than to any other group.
15) Both *Coryphospingus* and *Rhodospingus* finches, likewise treated within Emberizidae, are allied with Thraupidae and are closest to *Lanio*, *Eucometis* and *Tachyphonus*.
16) The *Paroaria* cardinals, currently treated as emberizids, appear to belong in Thraupidae.
17) *Diglossa* flowerpiercers, having been transferred by some authors from Thraupidae to Emberizidae, are now considered to be firmly allied with Thraupidae.
18) The Swallow Tanager (*Tersina viridis*), an enigmatic species previously placed either in Thraupidae or, sometimes, in a family of its own, is now known to be allied with Thraupidae and is closest to *Dacnis* and *Cyanerpes*.
19) *Saltator* is apparently genetically closer to the thraupids than to the cardinalids, but could possibly be sister to the latter, with which it is currently included; the genus *Saltator* as currently constituted is polyphyletic, with one member, the Rufous-bellied Saltator (*Saltator rufiventris*), most closely aligned with *Delothraupis* and *Dubusia* in Thraupidae.
20) *Parkerthraustes* appears most closely related to Thraupidae, and is not a cardinalid.
21) The monotypic Blue Finch (*Porphyrospiza caerulescens*) should be included in Thraupidae, rather than, as presently, in Emberizidae, and is sister to the Band-tailed Sierra-finch (*Phrygilus alaudinus*).

Another tanager genus that resembles the New World warblers (Parulidae) in appearance and behaviour is Thlypopsis. *The six small, delicately proportioned species in this genus form a tightly knit group, characterized by orange, rufous or chestnut colouring on the head of the male. Some, like the* ***Rust-and-yellow Tanager****, are relatively brightly coloured; others, such as the Buff-bellied Tanager* (T. inornata), *rather plain. The females are generally duller: the female Rust-and-yellow Tanager, for example, has a buffy-yellow forehead only tinged with rufous, and an olive crown.*

[*Thlypopsis ruficeps*, Machu Picchu Historical Sanctuary, Cuzco, Peru. Photo: Johannes Ferdinand]

22) The Yellow Cardinal (*Gubernatrix cristata*), currently included in Emberizidae, appears most closely related to Thraupidae.
23) The Coal-crested Finch (*Charitospiza eucosma*), currently included in Emberizidae, appears most closely related to Thraupidae.

The word *tangará* first appears in scientific writing in 1648, in G. Marcgraf's treatise on plants and animals. Some confusion arose when Linnaeus, transposing two letters, created the generic name *Tanagra* and applied it to euphonias; this also led to the creation of the family name Tanagridae. Both names were officially suppressed by the International Commission on Zoological Nomenclature in 1968. The correct name for the family as traditionally recognized became Thraupidae, derived from the Greek word *thraupis*, which was first used as a valid name by F. Boie in 1826; this word was based on the usage of Aristotle, who was referring to a kind of finch.

As mentioned above, tanagers represent part of an immense radiation of New World nine-primaried oscines. These comprise a group of birds that are fairly uniform in body shape, but with considerable variation in body size, the largest being almost ten times as heavy as the smallest, and with marked variation in habitat preferences, plumage patterns and colours, feeding behaviour and bill shape. Bill shapes, in particular, have been utilized extensively in the past as clues for classification, but recent phylogenetic studies have revealed that bill morphology is not a reliable indicator of ancestry. Partly as a result of an over-emphasis on bill shapes, which are subject to rapid evolution as feeding pressures change, the traditionally defined tanager family is not monophyletic and represents an artificial grouping of genera and species. Convergent evolutionary pressures often cause two or more taxa to look similar and appear to be related when they may, in fact, be quite unrelated. Since about 1990, studies of molecular genetics have helped to shed light on many of these thorny matters of relationships, and the family Thraupidae, as presently understood, includes various genera formerly placed in other families. Conversely, these studies reveal also that several genera previously classified as tanagers are unrelated to them, and should be transferred to Emberizidae, Cardinalidae or Fringillidae; for example, some authors have already transferred *Euphonia* to Fringillidae. As a result of these continuing rearrangements and exchanges, tanagers may eventually encompass some 350 to 400 species. Compared with traditional arrangements, this represents an increase of up to about 40%, and accounts for approximately 8–10% of all Neotropical avian species.

Tanagers are now the most diverse avian group for which phylogenetic relationships can be reconstructed. They are entirely New World in origin and distribution, and are largely non-migratory. Speciation rates vary, some lineages appearing relatively early, for instance in the middle Miocene, about 15 million years ago, whereas others are part of large recent radiations during the middle to late Pleistocene, dating only to about 0·5 million years

Fewer than half of the true thraupids exhibit strong sexual dichromatism, where the males are brightly coloured or boldly marked, and the females are plainer combinations of olive, brown or buff, with paler underparts. The female ***Chestnut-headed Tanager*** *is much duller than the male, with dull rufous and buff replacing the dark chestnut of his hood, a brownish-olive back, and greyish-buff underparts. Males, however, may take a considerable time to gain their full plumage. Immature males resemble females, and individuals are often seen with some grey in their plumage and a little chestnut on the head.*

[*Pyrrhocoma ruficeps*, Santa Rita de Caldas, Minas Gerais, Brazil. Photo: Geiser Trivelato]

Described only in 1976 from a specimen collected at Bosque Unchog, in the Peruvian Andes, the location of this picture, the ***Pardusco*** *was variously thought to be a primitive tanager or New World warbler (Parulidae), or genetically somewhere between the two. Investigations of cytochrome* b *sequence data indicate that it is close to the clade that includes the* Hemispingus, Thlypopsis *and* Pyrrhocoma *tanagers, among others. A very plain brown tanager, the Pardusco has few distinguishing marks and features other than its slender bill with a flesh-coloured lower mandible, and its yellowish soles. The sexes are similar.*

[*Nephelornis oneilli*, Bosque Unchog, Huánuco, Peru. Photo: Samuel Hansson]

Tanagers in the genera Trichothraupis, Tachyphonus, Lanio, Eucometis, Coryphospingus *and* Rhodospingus *form a large, monophyletic clade. Shared features, as illustrated by the* ***Black-goggled Tanager****, include sexual dichromatism, and a crest or patch of colourful feathers on the crown of the male. The yellow crown patch of the Black-goggled Tanager is usually concealed or, as here, shows as a narrow yellow stripe. Most of this clade of tanagers have a lowland distribution; the Black-goggled Tanager, however, has two geographically well-separated populations, one primarily lowland and the other montane.*

[*Trichothraupis melanops*, Intervales State Park, Ribeirão Grande, São Paulo, Brazil. Photo: Edson Endrigo]

ago or less. As a group, they exhibit a wider range of feeding adaptations than was previously realized. Once thought to comprise mainly fruit-eating species, or more omnivorous fruit-eating and insect-eating species, they are now known to include nectar-feeding *Diglossa* and several seed-eating genera, as well. Many have generalized diets that include various combinations of these food items. Specialization on seeds is significant, because no seed-eating group had previously been included in the family, and this behaviour provides evidence that tanagers have successfully colonized almost all major terrestrial habitats in the Neotropics.

One of the most striking features of tanagers is the variety of colourful plumages. Their colours are often brilliant, conspicuous and boldly contrasting. A few species, however, are dull and nondescript, even cryptic. About half are sexually dimorphic, the males having much brighter colours than do the females. In addition, tanagers vary in their nesting habitats, foraging strategies and tendency to migrate, and also in other aspects of behaviour. A considerable body of ecological and behavioural information is now available for many species of tanager, but what has been lacking until very recently is a rigorous phylogenetic framework for the group. Now, as a result of molecular studies, a nearly complete phylogeny is available, and this has permitted the construction of an evolutionary timeframe for the history and radiation of this remarkable group of birds.

Early classifications of tanagers were, in common with other avian groups, linear sequences based on features of plumage, various morphological characters, and geographical distribution. The purpose of these constructions was to reflect a general ancestry, beginning with presumed oldest genera and species and ending with more recently evolved members. Linear sequences, however, were never intended to recapitulate true phylogeny; they may include polyphyletic groups and they are heavily biased towards morphological similarities. They have remained controversial and subject to frequent revision. Molecular phylogenies, on the other hand, attempt to identify strictly monophyletic groupings, called "clades", by using binary branching trees (dendrograms). Nevertheless, the science of molecular phylogenetics, a genealogy-based system, is not without its critics, who point to the difficulty of defining clades, which can represent almost any taxonomic unit from two species to a family or even more, to the lack of a process for naming species, and to its dependence on inherited traits. Gradual improvements in molecular gene-sequencing has helped to clarify many controversial intrageneric relationships within tanagers and has uncovered surprising new ones, as well. In some cases, sequences of cytochrome *b* gene data, for example, have supported earlier sequential taxonomic predictions based on morphology, but in other cases they have not. Some examples of striking agreement between classic morphological taxonomy and cytochrome *b* data are the adjacent grouping of pairs of genera, including *Chlorophonia* and *Euphonia*, *Delothraupis* and *Dubusia*, *Hemispingus* and *Cnemoscopus*, *Hemithraupis* and *Chrysothlypis*, and *Dacnis* and *Cyanerpes*. The phylogenetics of these genera, and of groups whose relationships differ from those indicated in earlier taxonomic sequences, are discussed in the following paragraphs.

In their detailed studies of the world's birds based on analyses of DNA–DNA hybridization, Sibley and Ahlquist upset many long-cherished notions regarding avian relationships. They noted, for example, that several purported tanager taxa, including *Habia*, *Piranga*, *Chlorothraupis*, *Chlorospingus*, *Phaenicophilus*, *Spindalis*, *Nesospingus*, *Euphonia*, *Chlorophonia*, *Lamprospiza* and *Mitrospingus*, appeared not to be closely related to other members of the group that they termed Thraupini. Moreover, they found that some 60 other genera included in their studies did form a monophyletic clade of Thraupini. These and their many other studies ultimately formed the basis for what was at the time a controversial work, the Sibley and Monroe checklist, published in 1990. Since that landmark publication, many, though not all, of Sibley and Ahlquists's findings have been found to agree, at least broadly, with the results of more sophisticated recent molecular studies and analyses. The flood of publications emanating from molecular-genetic studies aimed at resolving the taxonomies of specific groups continues, and it seems that, at long last, Sclater's taxonomic conundrum may be solved. By the time the present volume appears in print, in fact, molecular biologists will almost certainly have a complete phylogeny of tanagers.

The early fossil record of tanagers is essentially non-existent, as it is for most oscine passerines, and it provides no help in determining origins, history or early relationships within the family. Furthermore, without the luxury of a fossil calibration for erecting a temporal framework within which to examine patterns and rates of diversification, biologists must turn to genetic-based

Most classifications recognize eight species of Tachyphonus, *which are slender, medium-sized tanagers with a narrow bill. The males are predominantly black, with patches of semi-concealed red or yellow in the crown. They also have white, yellow, buff or red at the bend of the wing, on the wing-linings, or in the form of epaulets or flank tufts. Several males also have a yellow or buff rump. The females of all species are olive to brownish and very unlike the males. The genus* Tachyphonus, *however, does not represent a monophyletic group. Three species, including the* ***Ruby-crowned Tanager*** *(above), appear to be more closely related to the tanagers of the genus* Ramphocelus *than to other* Tachyphonus. *All three lack the obvious crest that is present in all other species of* Tachyphonus, *such as the* ***Flame-crested Tanager*** *(below), and in habitat and behaviour are much more like* Ramphocelus. *The Ruby-crowned Tanager and the Brazilian Tanager* (R. bresilius) *are known to hybridize in captivity, providing more evidence of a close relationship between these two lineages. Though widespread, the Ruby-crowned Tanager is monotypic. In contrast, ten subspecies of Flame-crested Tanager are currently recognized, differing mainly in the colour of the crest and the size and colour of the male's throat patch. The race* brunneus, *shown here, has a longer and fuller crest than the nominate. But, given the amount and complexity of variation between some races and the relatively trivial differences between others, a full taxonomic review is probably warranted.*

calculations. The use of a mitochondrial DNA (mtDNA) evolutionary rate of approximately 2% sequence divergence per million years has been utilized, but this rate is based on data for geese (Anatidae). Recent data have confirmed a more generalized rate for many birds, including some tanagers, of 2·1% sequence divergence per million years. Despite limitations and criticisms, mtDNA-sequence divergence is currently regarded as the most reliable marker for making inferences about historical time frameworks when supporting fossil data are unavailable.

Using a large clade of "core" tanagers, R. Sedano and Burns were able to examine historical diversification and biogeography of tanagers. Their group contained almost one-third of all tanagers, included species found at a range of elevations from sea-level to the tree-line, and contained representatives from 18 of 22 zoogeographical areas in Middle and South America and the Caribbean. Included in this core group were species in the genera *Anisognathus*, *Buthraupis*, *Bangsia*, *Calochaetes*, *Chlorochrysa*, *Chlorornis*, *Cissopis*, *Delothraupis*, *Dubusia*, *Iridosornis*, *Neothraupis*, *Paroaria*, *Pipraeidea*, *Tangara*, *Thraupis* and *Schistochlamys*, as well as *Stephanophorus*, *Wetmorethraupis*, *Diuca* and *Lophospingus*, the last two currently treated in Emberizidae. Their analysis identified the northern Andes as the most probable ancestral area of the group, with the most recent common ancestor of the group-members being a highland species. Their reconstructions indicate that 51 dispersal events occurred during the history of these core tanagers, the greatest number of early dispersal movements being out of the northern Andes, rather than into this area. The south-central Andean region also had more outward dispersals than inward ones, but this area experienced far fewer dispersal events than the northern Andes. Slightly more than half of all dispersals involved horizontal exchanges with other montane regions, whereas less than a quarter of exchanges were between the Andean highlands and the lowlands. Most speciation events occurred either within highland areas or within lowland areas, with relatively few exchanges between the two. When these highland–lowland exchanges did occur they were predominantly from the highlands to the lowlands, and not vice versa. When lowland-to-highland dispersals were identified they occurred late in the tanager phylogeny, well after many key dispersal events out of the Andes took place.

The biogeographical history of these core tanagers reinforced early ideas regarding the importance of the Andes in bird diversification, and the fact that there has been some exchange between highland and lowland areas. While Middle America has been the source of some non-tanager avian lineages, this was not, however, the case with the core tanagers. All evidence suggests that dispersal events occurred only from the Andes north-westwards into Central America, with subsequent diversification. Examples include the Blue-and-gold Tanager (*Bangsia arcaei*), Emerald Tanager (*Tangara florida*) and Silver-throated Tanager (*Tangara icterocephala*), and the most recent common ancestor of the Spangle-cheeked (*Tangara dowii*) and Green-naped Tanagers (*Tangara fucosa*). In addition, most Andean tanagers in the core group appear to have derived from other Andean tanagers, and not from adjacent lowland counterparts. Biogeographical reconstructions also indicate that core tanagers dispersed into the tepuis, although no unambiguous dispersal of core tanagers out of the tepuis could be identified.

With the general importance established of the Andes as a centre of diversification of core tanagers, the next piece of the puzzle involves matching dispersal events in geological time. Andean uplift occurred earliest in the southern region and followed a general south-to-north progression. Thus, mountain-building was completed earliest in the southern region, followed by the central region and, finally, the northern region, the last comprising mainly the present-day Andes of Colombia and Venezuela. After a slow rise for millions of years, the central Andes reached about half their present height. The final, much more rapid uplift was completed between about 10 million and 6 million years ago, whereas the eastern Andes of Colombia did not reach modern-day heights until about 5·5–3·3 million years ago. Molecular-clock calculations show core tanager diversification dates to about 5–4·1 million years ago, thus occurring after the final uplift of the central Andes, but remarkably coincident with the final orographic uplift of the northern Andes. The drivers of speciation at this point in history could have included mountain-building uplift, habitat changes, climatic cycles and tectonic activity, any or all of them providing opportunities for isolation and subsequent speciation. The analysis also indicates that speciation rates have gradually slowed following the final uplift period.

Extreme glacial cycles of the late Pleistocene have often been cited as important drivers of speciation, responsible for generating much modern-day diversity. Molecular-clock calculations, however, indicate that most speciation in this core tanager clade,

The shrike-tanagers of the genus Lanio *have a long, straight, heavy bill with a sharply hooked tip. There are four recognized species, two in Middle America and two, the* ***White-winged Shrike-tanager*** *and the Fulvous Shrike-tanager* (L. fulvus), *in South America. But, although they replace each other on either side of the Amazon River, the two South American species do not, as previously thought, form a superspecies: the Fulvous Shrike-tanager is more closely related to the Middle American species. Female shrike-tanagers tend to be of a uniform brownish colour, in contrast to the dramatic black and yellow or black and orange of the males.*

The males of the genus Ramphocelus *exhibit some of the most intense velvety blacks and reds to be found in nature. The Flame-rumped Tanager* (R. flammigerus) *and the* ***Lemon-rumped Tanager*** *(above) are usually treated as conspecific, despite their striking visual differences. The middle back to the rump and the uppertail-coverts of the two species are, respectively, flame-scarlet and lemon-yellow. Genetic differences between the two species are apparently minimal, and they interbreed freely in the western Andes of Colombia, where recent deforestation has permitted them to expand their ranges and to meet. The bill of both the Flame-rumped and the Lemon-rumped Tanagers is blue-grey, with a black tip in the case of Flame-rumped species. Other male* Ramphocelus *tanagers, such as the* ***Brazilian Tanager*** *(below), have a stout bill with a black upper mandible and tip, and the basal two-thirds of the lower mandible swollen and chalky white. This expanded white portion of the bill is conspicuous even at a distance, especially against the velvety black or red plumage. Female* Ramphocelus *tanagers have a bill that is thick but of a more normal shape, and their lower mandible is pale grey.*

A recent molecular study found that the well-known and long-established tanager genus Thraupis *was not, as had previously been supposed, monophyletic. Six of the eight species sampled belong in the genus* Tangara, *while the remaining two, the Blue-capped Tanager* (T. cyanocephala) *and the* ***Blue-and-yellow Tanager*** *(above), are placed within a large clade of montane tanagers of several genera. These two species do not appear to be closely related to each other, but both are unusual in having an exceptionally long, linear geographical distribution, and displaying a high amount of geographical variation. The Blue-and-yellow Tanager is a mostly open-country tanager that becomes much brighter in plumage in the southern portion of its range. Its dullest race,* darwinii, *which also differs in song from the other races, is sometimes treated as a separate species. The* ***Golden-chevroned Tanager*** *(below) is one of the six* Thraupis *species embedded within* Tangara. *The six are one another's closest relatives; they are larger and plainer in plumage than previously recognized* Tangara *tanagers. Even before the transfer of these six species,* Tangara *was the largest Neotropical bird genus.*

*The long, heavy bill of the **Blue-backed Tanager**, with its decurved culmen, is unique among the Thraupidae. The upper mandible is black, the lower mandible grey. The Blue-backed Tanager is also relatively unusual in having yellowish-orange legs. Females are duller than males, although the male's vivid blue plumage also becomes duller and greener on the back and rump as it wears. This species is confined largely to Guianan forests from extreme eastern Venezuela eastwards across Guyana and Suriname to French Guiana. There are also three tiny and presumably isolated populations in central Amazonian Brazil.*

as well as other tanager groups, took place prior to these Pleistocene events. Only a few lineages of core tanagers appear to have diversified within the last 800,000 years, when glacial cycles have been at their most extreme. The appearance of *Tangara* represents one of the more recent tanager speciation events, but with high levels of speciation occurring during the late Pliocene–early Pleistocene, even in this case most of the events still predate the middle Pleistocene. Recent northern Andean speciation events that do correspond with Pleistocene glacial cycles include a clade containing the Burnished-buff Tanager (*Tangara cayana*), Scrub Tanager (*Tangara vitriolina*) and Lesser Antillean Tanager (*Tangara cucullata*), and the separation of the Moss-backed Tanager (*Bangsia edwardsi*) and Gold-ringed Tanager (*Bangsia aureocincta*).

The relatively recent speciation and radiation of *Tangara* in the Andes is mirrored by *Sporophila* seedeaters, another historically recent tanager radiation that has been confined largely to areas south of the Amazon River. The majority of *Sporophila* are today still found south of the Amazon, and they are so minimally divergent genetically that a rapid radiation has probably occurred only within the last half-million years. The reasons for rapid diversification within *Sporophila* are obscure, but they could include successive marine ingressions and regressions, the use of specific habitats during short-distance seasonal movements or longer migrations, and adaptations to specific, patchy grassland habitats that were persistent. Factors that drove speciation in this group are, at least for the moment, buried in history.

Numerous core tanagers occur in Middle America, where they can be found in both the highlands and the lowlands. Phylogenetic gene trees indicate that these core tanagers originated from South American taxa, and not from ancestors in Middle America. Dispersal events into Central America occurred about 2·9 million years ago, a date that coincides with the general closing of the Panama isthmus, estimated to have taken place 3·5–2·5 million years ago. Variation in dates of speciation events indicates that land-bridge closure influenced some species more than it did others, but it was significant in the evolutionary history of birds, as well as mammals.

Tanagers are predominantly a South American group. More than 70% of the species occur in South America, and their greatest diversity is in low tropical latitudes, progressively fewer having spread northwards into Central America and southwards into the cone of southern South America as far south as Tierra del Fuego. Tanagers are also well represented in Trinidad, a continental island close to northern South America, to which it had a recent geological connection. There are fewer on nearby Tobago, which shares no such recent connection with the continent, despite its close proximity. Tanagers are also distributed on Caribbean islands, and their presence on many islands is likely the result of early dispersals from South America.

Tanager diversity peaks in the humid Andean foothills and lower montane zones. Fjeldså and Rahbek mapped tanager diversity across South America and found peaks of diversity in five regions: 1) south-western Colombia and adjacent north-west Ecuador; 2) south-eastern Ecuador; 3) Huánuco, in central Peru; 4) Apurímac and adjacent Cuzco, in south Peru; and 5) La Paz, in Bolivia. The next highest level of diversity occurs in the Atlantic Forest of Brazil and broadly in the Colombian and Venezuelan Andes, followed by the Planalto de Mato Grosso of Brazil west to the Bolivian border, and the Guiana highlands from southern Venezuela eastwards across the Guianas. Tanager species richness is generally lowest across much of the Amazon Basin. This seems counter-intuitive when one considers that popular knowledge inevitably emphasizes the enormous diversity of the Amazon region. Bearing in mind the enormous size of the region, however, the species richness of tanagers in Amazonia is not particularly high. About half of all tanagers in South America have very small ranges, estimated at less than about 50 equatorial 1°× 1° grid-cells, an area slightly larger than Ecuador. These species are heavily concentrated in the Andes, where their distributions are narrow and linear, with the highest density in the Colombian Andes and in northern Ecuador. Even when areas three times as large are included, such species are still clustered along the Andean cordillera. On the other hand, species with large distributions are found mainly in the Amazon Basin and the Guianan and Brazilian Shield areas.

Early taxonomic work on tanagers, as well as that on many other groups of birds, relied heavily on morphological characters, especially external characters associated with the bill and legs. As noted previously, bill morphology, in particular, has been over-emphasized as a taxonomically informative character for nine-primaried oscines, as bill shapes are strongly influenced by selection for particular feeding adaptations, can change rapidly, and may bear little relationship to ancestral lineages. Although modern molecular studies have helped to define the limits of tanagers in ways not possible when using phenological characters, other types of information that have been utilized successfully elsewhere in avian taxonomy either have not been helpful

The five Bangsia *tanagers are small and short-tailed, rather robust and chunky in build, and with a thick, stubby bill. Two members of the genus, the* ***Moss-backed Tanager*** *and the Gold-ringed Tanager* (B. aureocincta), *separated as recently as 800,000 years ago. Both are confined to the Chocó–Pacific slope region.* Bangsia *is sometimes subsumed in the mountain-tanager genus* Buthraupis, *but this is not supported by recent molecular-genetic studies. As well as their morphological differences, including their relatively uniform plumages, the* Bangsia *tanagers are less social and occur mostly at lower elevations.*

[*Bangsia edwardsi*, Mashpi Road, Ecuador. Photo: Robert Lewis]

or have not been explored for the Thraupidae. For example, nest architecture has proved to be a taxonomically useful character at the generic level, because it is conservative and can differ markedly among families and genera. Phylogenies based on a single suite of characters, however, are rarely used alone, without supporting data from other sources. The nest structure of tanagers is rather uniform across most genera (see Breeding), and may have limited taxonomic value.

Behavioural information offers additional taxonomic characters for analysis, but few detailed behavioural studies of tanagers have been undertaken. M. Moynihan, working mainly in Panama, documented behaviour patterns related to movements, aggression, and social and sexual aspects for two species of *Ramphocelus* tanagers and two species of *Chlorospingus* bush-tanagers, but little work has been conducted on other thraupid species and the relevance of behaviour as a taxonomic aid within the family is at present limited. The widespread use of digital video may encourage the examination of behaviour as a tool in taxonomy.

Vocal characters have been employed quite successfully as a taxonomic tool in defining the generic and species limits of birds, especially in the suboscine families Furnariidae (ovenbirds), Thamnophilidae (typical antbirds) and Rhinocryptidae (tapaculos). In these groups, unlike oscine passeriforms, the songs, calls, duets and other vocalizations of males and females are largely inherited, rather than learned, and are generally more stable. Tanagers, on the other hand, often have complex songs that are extremely high-pitched and difficult to record and analyse successfully. The vocal repertoires, and even the basic songs, of some species, such as the *Tangara* tanagers, are still unknown. Systematic cataloguing of tanager vocalizations is, at this point, in its infancy and, while vocal analysis has been used successfully for birds ranging from tinamous (Tinamidae) and some raptors, such as the *Micrastur* forest-falcons, to tyrant-flycatchers (Tyrannidae), and for some oscine groups, such as wrens (Troglodytidae), vireos (Vireonidae), various assorted warblers and others, it has thus far received rather minor attention with respect to tanagers.

Molecular phylogenetics are perhaps the single most important tool being used at present in attempts to determine the monophyly of groups and to assign relationships on the basis of genealogy. The following paragraphs discuss recently published information on the systematics of selected groups, as well as, in some cases, comments on their biogeographical histories.

Several tanager genera, notably *Hemispingus*, *Thlypopsis*, *Erythrothlypis* and *Chrysothlypis*, are small-bodied, thin-billed birds that resemble some parulid warblers. *Hemispingus* tanagers are so similar morphologically to *Basileuterus* warblers that there are few morphological features that constantly separate the two genera. Most species in both genera have a striped head pattern, plain upperparts and paler unmarked underparts, as well as a normal, square to slightly notched tail. The bill is relatively thin in both genera, although slightly heavier in *Hemispingus*. Moreo-

The four Buthraupis *species are large, social mountain-tanagers of high elevations, and having yellow underparts. The bill is short and stubby. Despite their sometimes spectacular appearance, some species, such as the* ***Black-chested Mountain-tanager****, can be quiet and hard to find. It moves slowly and methodically within dense foliage and sometimes sits quietly without moving for minutes at a time. The largest* Buthraupis *species, however, the Hooded Mountain-tanager* (B. montana), *is noisy and conspicuous, occurring in groups of up to ten birds which sometimes give simultaneous bursts of loud squealing notes.*

[*Buthraupis eximia eximia*, Chingaza National Park, Colombia. Photo: Ketil Knudsen]

The six Anisognathus *species are typical mountain-tanagers, with bold colourful plumage in both sexes. The* ***Santa Marta Mountain-tanager*** *(left) has a restricted range in Colombia, but the* ***Scarlet-bellied Mountain-tanager*** *(right), with four recognized races, is distributed along the Andes from Venezuela south to Bolivia. These two species, together with the Lacrimose Mountain-tanager* (A. lacrymosus), *were formerly placed in a separate genus,* Poecilothraupis.

[Left: *Anisognathus melanogenys*, El Dorado, Colombia. Photo: Pete Morris.

Right: *Anisognathus igniventris igniventris*, Carrasco National Park, Cochabamba, Bolivia. Photo: Daniel Alarcón]

ver, vocal duetting is reported for members of both, although it is much better developed in *Hemispingus*, in which group singing involving up to five or more individuals is a regular feature of the song display of several species. Members of both genera are found primarily in the lower or middle storey of forest, but a few species of *Hemispingus* spend much time on or close to the ground and numerous species are closely associated with *Chusquea* bamboo. A second group of parulid-like species includes *Erythrothlypis* and *Chrysothlypis*, each containing a single species. *Erythrothlypis* has sometimes been subsumed into the latter genus. The two species are rather similar in size, body mass and bill shape, and both are sexually dimorphic, but they differ markedly in plumage colour and pattern. Male Scarlet-and-white Tanagers (*Erythrothlypis salmoni*) are salmon-red and white, whereas male Black-and-yellow Tanagers (*Chrysothlypis chrysomelas*) are boldly patterned in black and yellow; thus, beyond general shape, the two look utterly different. Both are active, sprightly little tanagers that glean insects in foliage, but the Scarlet-and-white depends heavily on arillate fruits at times, and includes much small fruit in its diet, while the Black-and-yellow Tanager is more insectivorous. *Thlypopsis* comprises a third group of small, delicately proportioned, warbler-like tanagers that are similar to one another morphologically and are almost certainly monophyletic. They are restless, highly arboreal birds that search actively in foliage, mostly for insects, and take relatively little fruit. This small, tightly knit group includes one species widespread in lowlands and five montane species with mostly small, non-overlapping distributions. Although they recall warblers in behaviour, molecular studies support their placement within Thraupidae.

While several studies have focused on the evolution of tanagers in highland areas of the Andes and Central America, there has been, until recently, relatively little work on lowland groups. In 2009, however, Burns and Racicot published a phylogenetic examination of a large number of lowland tanagers and allies distributed from southern Mexico south to Argentina. This study was the first to examine phylogenetic relationships of tanagers across lowland Neotropical America and, in particular, to explore the importance of Middle America and the role of the Panamian land-bridge in the historical radiation of tanagers and its timing. Within the group that they examined were core species in mixed flocks, some species with crests, some with bright plumages and a majority with sexually dimorphic plumages, although, in the case of two species, the females were as brightly coloured as their male counterparts. These authors' results revealed a large, monophyletic clade of lowland tanagers that included all species of *Tachyphonus*, *Ramphocelus*, *Trichothraupis*, *Eucometis*, *Lanio*, *Coryphospingus* and *Rhodospingus*. The species in this group had not previously been suspected of forming a monophyletic clade, although some earlier studies had indicated that certain members were related to one another. Shared features of the group include a predominantly lowland distribution with the single exception of the Huallaga Tanager (*Ramphocelus melanogaster*), which is found mainly in the foothills; none occurred above 1700 m in elevation. Interestingly, most of the species were sexually dimorphic, with males much brighter than females, and several were crested or had semi-concealed patches of colourful feathers on the crown. The study also indicated, for the first time, that the two species in the genus *Coryphospingus* and the single species in *Rhodospingus* were more closely related to the tanagers than to the emberizids, where they had long been placed. It was noted also that, in addition to DNA corroboration, these species have bold red-and-black plumage, a relatively thin bill and a crest, characters more closely aligned with tanagers than with emberizids or finches.

One of the more surprising findings of the Burns and Racicot study was that the genus *Tachyphonus* did not, as constituted, represent a monophyletic group. Most classifications recognize eight species of *Tachyphonus*, which are rather slender, medium-sized tanagers with a narrow bill. The males are predominantly black, often with patches of semi-concealed red or yellow in the crown, and white, yellow, buff or red at the bend of the wing and on the wing-linings, or they have semi-concealed coloured pectoral tufts and flank tufts. Several males also have a yellow or buff rump. Females of all species are olive to brownish, and very unlike the males. Three species of *Tachyphonus*, however, appear to be more closely related to *Ramphocelus* than to other *Tachyphonus*. These are the White-lined Tanager (*Tachyphonus rufus*), Ruby-crowned Tanager (*Tachyphonus coronatus*) and Red-shouldered Tanager (*Tachyphonus phoenicius*), all three of which lack the obvious crest that is present to some extent in all other species of *Tachyphonus*. Furthermore, these three species, as with *Ramphocelus*, live in shrubby forest borders, second growth and semi-open habitats, where they stay low down. In habitat and

An unmistakable large and robust tanager with bright green plumage, a chestnut mask and orange bill, legs and feet, the ***Grass-green Tanager*** *is the sole species in the genus* Chlorornis. *The position of this genus has for long been the subject of debate. Although its plumage is quite distinct, the Grass-green Tanager resembles a* Buthraupis *mountain-tanager in its foraging and social behaviour and vocalizations. Recent molecular-genetic studies suggest that two members of* Buthraupis, *the Golden-backed* (B. aureodorsalis) *and the Black-chested Mountain-tanagers* (B. eximia), *are more closely related to* Chlorornis *than to other* Buthraupis *tanagers.*

[*Chlorornis riefferii riefferii*, Ecuador. Photo: Tui de Roy/ Roving Tortoise Photos]

behaviour, therefore, they are much more like *Ramphocelus* than like other *Tachyphonus*. Burns and Racicot also point out that the Brazilian Tanager (*Ramphocelus bresilius*) and Ruby-crowned Tanager are known to hybridize in captivity, another line of evidence indicating a close relationship of these two lineages. These researchers recommend that the taxonomy of *Tachyphonus* be revised, with two or three suggested possible alternatives. The first would be to place all species in the genera *Tachyphonus*, *Ramphocelus*, *Trichothraupis*, *Eucometis*, *Lanio*, *Coryphospingus* and *Rhodospingus* into a single enlarged genus, the name *Ramphocelus* having priority. A second alternative put forward by Burns and Racicot was the splitting of these seven genera into two clades, one under *Ramphocelus* and the second under *Lanio*, as these two genera are the oldest named and would have priority. A third and more complex possibility would be to retain traditional generic limits and to place the three monophyletic species of *Tachyphonus*, namely *T. coronatus*, *T. rufus* and *T. phoenicius*, within *Ramphocelus* because they are the sister-group of *Ramphocelus*. As the present *Tachyphonus* is not monophyletic, however, three new genera would need to be named for the remaining five species: one for the monotypic Tawny-crested Tanager (*Tachyphonus delatrii*) of lower Central America and western Colombia; another for the Fulvous-crested Tanager (*Tachyphonus surinamus*); and a third for the remaining three species. Other allied species, including *Eucometis*, *Trichothraupis* and *Rhodospingus*, would likewise require re-evaluation. Striking visual differences among members of these genera suggest that this last approach may be preferable.

Surprising also in the Burns and Racicot study were the high levels of intraspecific sequence divergence identified for some species. This is an area of investigation still in its infancy, and one destined to engender considerable interest and debate in the future. The Flame-crested Tanager (*Tachyphonus cristatus*), with ten named subspecies, was visually the most variable species examined by Burns and Racicot. They sampled only two individuals, one from Peru and the other from nearby Bolivia, and found a sequence divergence of 2·5%, a remarkably high level for two individuals that are separated geographically by a relatively short distance in which no physical barriers impede gene flow. Even higher levels were found in the White-shouldered Tanager (*Tachyphonus luctuosus*), another variable species: an individual from Peru differed from one in eastern Panama by 2·5%, but one from Honduras differed by 4·8% from the other two populations. Two Grey-headed Tanagers (*Eucometis penicillata*) in eastern Bolivia differed from each other by only 0·35%, but were 4·8% divergent from an individual in Panama. The importance of these findings is that, in each case, the individuals involved exhibited levels of genetic divergence that are as high as or higher than those found between many currently recognized species and many genera. Such findings, if extended to other taxa across South America, suggest that many populations may in reality consist of multiple, if somewhat cryptic, species-level evolutionary units. High divergence values were also obtained from other species, including, rather surprisingly, a Lemon-rumped Tanager (*Ramphocelus icteronotus*) in Panama and another in Ecuador that differed by 2·2%. Levels of sequence divergence between most other *Ramphocelus* species varied from 2·4% to 4%. The lowest values were those separating the Silver-beaked Tanager (*Ramphocelus carbo*) and the Huallaga Tanager, which differed by just 1·1%. Genetic divergence between two controversial species in Costa Rica and Panama, the west-slope Cherrie's Tanager (*Ramphocelus costaricensis*) and its Caribbean counterpart the Scarlet-rumped Tanager (*Ramphocelus passerinii*), was also relatively low, at 1·8%, the two having been split on the basis of molecular data. Sequence divergence between these two, however, is lower than that observed for most other birds in the Burns and Racicot study, reflecting the fact that the two populations are largely isolated on either side of the mountain range running through lower Central America. Not surprisingly, the sequence divergence within each species was even lower, at 0·1% and 0·6%, respectively.

Sequence-divergence data also provide insights into historical events, and often the results are not entirely predictable. There are, for example, four currently recognized species of shrike-tanager (*Lanio*), two in South America and two in Middle America. The four species are monophyletic and occur primarily in the subcanopy of humid lowland forest. Sexual dimorphism is marked, the males being mainly black and burnt-orange to yellowish, while the females are mainly dull rufous. Morphologically, these shrike-tanagers are characterized by the possession of a slender body, a long tail and a prominently hooked bill, and they represent a lineage that appeared early in the evolution of

the family, most likely in Amazonia. The two species pairs are well separated geographically by the Andes. The two South American species are separated by the Amazon River and its major tributaries, the White-winged Shrike-tanager (*Lanio versicolor*) being found south of the river and the Fulvous Shrike-tanager (*Lanio fulvus*) occurring on the north side and extending northwards through the Guianas. In terms of genetics, sequence divergence between these two is high, at 7·0%, higher even than that between some tanager genera, which range from 6·2% to 16·4%. Despite close proximity, and the fact that the two were previously regarded as forming a superspecies, they are not, however, each other's closest relatives. The Fulvous Shrike-tanager is more closely related to the two species in Middle America, despite the wide geographical separation from the latter. Furthermore, the two Middle American species, the ranges of which approach each other in Honduras but do not overlap, differ by only 0·9%, this notwithstanding marked plumage differences, in addition to range separation. Such results could not be predicted by an analysis of plumage and distribution alone, and are worthy of further study because of multiple speciation events, including a recent one in Central America.

In a separate study of genus-level monophyly and relationships among tanagers, published in 2010, Sedano and Burns examined a wide variety of highland and lowland tanagers. Included within this study was a group of species distributed primarily in the lowlands east of the Andes and southwards into the austral region. This group contained tanager species and numerous genera previously classified as cardinalids and emberizids. The study revealed an interesting and well-supported clade that included *Stephanophorus*, *Diuca*, *Neothraupis*, *Lophospingus*, *Cissopis*, *Schistochlamys* and *Paroaria*. There are relatively few morphological characters or geographical or behavioural clues that would immediately unite these groups of birds. Relationships among some of these genera had already been partially resolved in earlier molecular-genetic studies, but the work by Sedano and Burns indicated that all of them belonged together in a single clade. Two of these genera, *Diuca* and *Lophospingus*, have traditionally been regarded as emberizid finches, and *Paroaria* has been placed with the latter or, more recently, with the cardinalids. Sedano and Burns' findings suggested that all of these species unambiguously belong with the tanagers.

Tanagers in the genus *Hemispingus* comprise a group of some 15 species that are mostly rather dull-coloured and restricted to the Andes. Four of them are polytypic, the Superciliaried Hemispingus (*Hemispingus superciliaris*) being composed of seven subspecies. Taxonomic relationships within the genus and, in particular, their relationship to certain *Basileuterus* warblers have long been a source of confusion. A partial mtDNA-gene study by García-Moreno, J. Ohlson and Fjeldså revealed that the genus is monophyletic, most of the diversity within it having evolved prior to the strong Pleistocene climatic cycling that began about 800,000 years ago. These researchers proposed a phylogeny containing three major clades: one with mostly greenish birds with a

Stephanophorus *is one of a number of monotypic genera found exclusively in the humid Atlantic Forests of south-eastern Brazil, adjacent eastern Paraguay and north-eastern Argentina. Although a colourful dark blue-violet when it perches in the open in a good light, the* ***Diademed Tanager*** *most often appears rather blackish. The white crown patch, however, is usually visible and the red tuft is also conspicuous. Diademed Tanagers favour dense, low cover, into which they are quick to dive when alarmed. To human eyes the sexes appear similar, but a study of museum skins that investigated ultraviolet wavelengths visible to birds revealed the existance of a "cryptic dichromatism".*

[*Stephanophorus diadematus*, Itatiaia City, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

The five Iridosornis *tanager species are confined to the Andes. The* ***Golden-collared Tanager*** *(left) and the* ***Golden-crowned Tanager*** *(right) are found at or near the tree-line, the remaining three species at lower elevations. In a pattern typical of many Andean tanagers, the Golden-crowned Tanager now occurs in a number of widely separated populations at high altitudes.*

Right: *Iridosornis rufivertex caeruleoventris*, Los Nevados National Park, Colombia. Photo: Pete Morris]

In size and body shape Tangara *tanagers are remarkably uniform, being small arboreal species with a stout, moderate-length bill, a tail of average length and a rather small but sturdy body. But there the similarities end:* Tangara *tanagers are remarkable for the diversity of their colourful and sometimes complex plumage patterns. In the majority of species, such as the* ***Golden Tanager*** *(above), the sexes are essentially identical, although males are usually slightly brighter. The nine races of the Golden Tanager are notable for their complex plumage variation, but the female is always duller than the male. In about 20% of* Tangara *tanagers, however, the females differ to varying degrees, sometimes substantially, from their mates. In the* ***Chestnut-backed Tanager*** *(below), for example, the entire crown, nape, side of head, mantle and back of the male are rich rufous-chestnut, but the female, apart from a rufescent crown and nape, is a dull greyish-green above. In fact, she is essentially identical to the female Black-backed Tanager* (T. peruviana), *with which the Chestnut-backed Tanager has been considered conspecific, the two then being regarded as partially localized morphs of a single species.*

[Above: *Tangara arthus sophiae*, Cock-of-the-Rock Lodge, San Pedro, Cuzco, Peru. Photo: Roland Seitre.

prominent eyebrow (*trifasciatus*, *atropileus*, *auricularis* and *calophrys*); a second with mostly grey, warbler-like birds (*superciliaris*, *verticalis* and *xanthophthalmus*); and a third with mostly ochraceous birds (*rufosuperciliaris*, *goeringi*, *piurae*, *frontalis* and *melanotis*). Subsequent analysis of mtDNA sequences by Burns indicated that *Hemispingus* is, itself, part of a clade of small tanagers of a mostly Andean radiation that includes also species of *Cnemoscopus*, *Pyrrhocoma*, *Thlypopsis*, *Nephelornis* and *Cypsnagra*. Most species in these genera are rather nondescript, although a few *Thlypopsis* are brightly coloured. Most are confined to the Andes, the few exceptions being *Pyrrhocoma*, which is a Brazilian species of south-east Atlantic Forest, *Cypsnagra*, which occurs in south-central Brazilian grasslands, and a few species of *Thlypopsis*. The Pardusco (*Nephelornis oneilli*), a recently described species endemic to central Peruvian elfin woodland, is unusual in that its nondescript plumage offers few clues to its relationships. Initially it was believed to be a primitive tanager or possibly a New World warbler. The cytochrome *b* gene data obtained by Burns placed it squarely within the present tanager clade and showed that it was unrelated to any parulid warblers included in the analysis. In general, early sequential taxonomies also tended to group these genera close to one another, and many also placed *Chlorospingus* close to *Hemispingus*. This latter relationship, however, was not borne out by the present DNA-sequence data, which suggested that the two genera were only distantly related. In fact, as will be seen below, *Chlorospingus* appears to be most closely related to some members of the Cardinalidae and is not closely related to the tanagers.

*The northernmost race of the **Golden-hooded Tanager** (above) occurs from the Caribbean slope of south-eastern Mexico southwards. The colours are richest in this northern race and become gradually paler, being palest in the southernmost subspecies* (fanny) *of eastern Panama, Colombia and western Ecuador. The Golden-hooded Tanager is relatively unusual for a* Tangara *species in being an infrequent or only transitory member of mixed-species flocks. The **Yellow-bellied Tanager** (below) is more typical in being frequently found in flocks including other* Tangara *species. (Some* Tangara *tanagers are found more often in groups with other members of their genus than with their own species.) A small, heavily spotted green tanager with a bright yellow belly, the Yellow-bellied Tanager gets its spotted appearance in part from the greenish-blue edges of the otherwise black feathers of its back, wings and tail. The feathers of its head and neck are, similarly, black with bright emerald-green edges.*

[Above: *Tangara larvata*, Panama. Photo: Mike Danzenbaker/ AGAMI.

Below: *Tangara xanthogastra phelpsi*, Canaíma National Park, Sierra de Lema, Bolívar, Venezuela. Photo: David Southall]

One surprising result of a recent molecular study by Sedano and Burns was the phylogenetic placement of *Thraupis*, a well-known and long-established genus composed of nine species. It seems that the genus as currently constituted is not monophyletic as has long been supposed, but that it should be split between two genera: six species embedded in the genus *Tangara*; and two, the Blue-and-yellow Tanager (*Thraupis bonariensis*) and Blue-capped Tanager (*Thraupis cyanocephala*), placed within a large clade of montane tanagers that includes *Buthraupis*, *Anisognathus*, *Iridosornis* and others; the Glaucous Tanager (*Thraupis glaucocolpa*) has not yet been analysed. Complicating the matter, however, is the fact that the Blue-and-yellow and the Blue-capped appear not to be closely related to each other. Members of the first group are each other's closest relatives and are embedded deep within *Tangara*, despite being considerably larger in length and weight than other *Tangara* and generally being plainer in plumage. With an additional six species transferred to *Tangara*, this group of birds, already the largest in the New World tropics, would become even larger.

DNA-based molecular phylogenetics reveal a distinctive clade that includes *Chlorornis*, *Dubusia*, *Buthraupis*, *Delothraupis*, *Anisognathus*, *Calochaetes* and one *Thraupis*, all of which are found only at high elevations in the Andes. These genera, in turn, are part of an even larger clade that includes *Bangsia*, *Iridosornis*, *Wetmorethraupis*, and *Pipraeidea*. Members of all of these genera are also found at higher elevations in the Andes from Venezuela south to Bolivia, with the exception of the single species of *Wetmorethraupis*, which occurs mainly in a foothill region.

Although brilliant colour is often seen as the defining feature of the genus Tangara, *a few of the species are notably plain. Dullest of the whole genus is the aptly named* ***Plain-colored Tanager****, which is mainly lead-grey, dull blue and blackish, except for the bright blue of its lesser upperwing-coverts; these, however, are usually concealed. The immature bird is even duller and plainer than the adult. Race* languens, *shown here, has a decidedly paler, more plain grey head and upperparts compared with the nominate, and the throat and chest are slightly paler grey.*

All species are notable for their bold, colourful plumages and lack of sexual dimorphism. These clades broadly correspond to more traditional taxonomic lineages but relationships within and between genera in DNA-based phylogenies frequently differ from more traditional taxonomies. For example, in 1970, Storer placed members of *Bangsia* in the genus *Buthraupis* and then positioned *Wetmorethraupis* next to *Buthraupis*, but newer DNA phylogenies reveal that neither *Bangsia* nor *Wetmorethraupis* is sister to *Buthraupis* and indeed they are not particularly closely related. In another example where old and new taxonomies differ, some authors in the past have argued that *Dubusia* and *Delothraupis* should be merged, but cytochrome *b* data indicate that these two genera are sister-taxa and that both should, or could be maintained. Also, the phylogenetic position of the monotypic *Chlorornis*, a large green-bodied, orange-billed tanager, has long been debated, and it has usually been listed as being of uncertain affinity. In 1886, Sclater considered it a finch in the genus *Saltator*, and in 1990 Sibley and Ahlquist, using data derived from DNA–DNA hybridization, believed that it was a sister-taxon to *Catamblyrhynchus*. Still other authors have noted similarities between the foraging behaviour of *Chlorornis* and that of *Buthraupis*. In recent molecular work, Burns and co-workers found that their cytochrome *b* data placed *Chlorornis* as sister to a clade containing the Golden-backed (*Buthraupis aureodorsalis*) and Black-chested Mountain-tanagers (*Buthraupis eximia*) but, surprisingly, not the widespread Hooded Mountain-tanager (*Buthraupis montana*). This last species, they found, might form a clade with the other three species, although they did not find strong molecular support for this. Furthermore, another species, the Masked Mountain-tanager (*Buthraupis wetmorei*), which was originally described in the genus *Tephrophilus*, proved to be only distantly related to other *Buthraupis*, a finding that corroborated the suspicions of the original describer.

The taxonomy of the mountain-tanager portion of the phylogenetic tree is further complicated by the presence of two species of *Thraupis*, namely the Blue-capped and Blue-and-yellow Tanagers, both of which are related to this clade but are not closely related to each other. These two *Thraupis* are unusual in that they have exceptionally long, linear geographical distributions and display a high amount of geographical variation. In yet another complication, the Vermilion Tanager (*Calochaetes coccineus*) also may belong with this clade of mountain-tanagers. Although traditionally placed near *Ramphocelus*, because of its glossy red-and-black plumage, and also near *Piranga*, because of its shape as well as some plumage similarities, *Calochaetes* more closely resembles some mountain-tanagers in habitat, behaviour and vocalizations. In addition, the sexes of *Calochaetes* are alike in plumage, a characteristic in which they are closer to mountain-tanagers than to *Ramphocelus* and *Piranga*, both of which are sexually dimorphic. Given these complications, Sedano and Burns suggest that, to accommodate so many species in a monophyletic arrangement, the simplest taxonomic

Recent genetic data indicate that, despite superficial similarities in appearance and diet, Chlorochrysa *tanagers are not particularly closely related to* Tangara. *The bill is longer and thinner than that of* Tangara, *but the most striking difference is in the legs, which are unusually strong and heavy because of their very active and acrobatic method of foraging. The male* ***Glistening-green Tanager*** *has a tuft of shining greyish-olive feathers behind his eye (usually inconspicuous, but clearly visible here), with a more conspicuous tuft of bright orange feathers immediately behind that. The orange feathers are thickened and club-like at the tips.*

[*Chlorochrysa phoenicotis*,
La Planada Nature Reserve,
Colombia.

The genus Dacnis *was previously regarded as part of a separate family, Coerebidae, but later placed in Thraupidae on the basis of similarities in skull anatomy. Dacnises are sexually dichromatic, the males being blue and the females greenish. The eight races of the* ***Blue Dacnis*** *differ mainly in the tone of blue (lighter or darker) of the male plumage and the colour of the head and back of the female. Both sexes of the Blue Dacnis have pinkish legs, and their irides are red to reddish-brown. Around half of the* Dacnis *species have red or yellow irides. The bills of* Dacnis *tanagers are among the thinnest and sharpest in the family.*

[*Dacnis cayana paraguayensis*, Itatiaia City, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

solution may be to unite this entire mountain-tanager clade, along with *Pipraeidea* and *Calochaetes*, in a single large "super" genus under the oldest applicable name, *Iridosornis*. Such a large and unwieldy generic grouping, however, may not gain acceptance until further corroborating work is undertaken, including an examination of the geographical variation in the two species of questionable *Thraupis*, the Blue-capped Tanager and the Blue-and-yellow Tanager.

The genus *Tangara*, with approximately 50 species, is the most species-rich genus in the entire New World, and it now seems destined to become larger still with the likely addition of several species currently placed in *Thraupis*. For the most part, it is composed of small birds of relatively uniform morphology and behaviour. All are confined to Neotropical latitudes and are perhaps best known for their often bold and colourful plumage patterns. Many are restricted in distribution and have specific habitat requirements, but they also are typically found together in sympatry with several other *Tangara* species. In the Andes, eight species are regularly sympatric and occasionally up to ten occur together; species occurring together in the Amazon are only slightly fewer. Several studies in the late 1990s supported the placement of the genus with other tanagers, but Burns and Naoki were the first to examine relationships within the genus. Using data from cytochrome *b* and ND2 genes, these researchers provided the first phylogenetic analysis of the diversity in this interesting genus, and addressed questions regarding its biogeographical history. Despite its large size, *Tangara* has been found to be monophyletic and composed of two distinct clades, these clades, in turn, being composed of about 12–13 species groups that generally correspond to those recognized in traditional taxonomies. Thus, genetic data supported the conclusions of earlier workers, who relied on plumage colour and pattern, distribution and behaviour.

In a reconstruction of the distributional history of *Tangara*, Burns and Naoki showed that the group, for the most part, originated in the northern Andes, and the two present-day clades that they identified were the result of an early split that occurred in that region. In addition, many speciation events subsequent to this split took place in the northern Andes. These researchers concluded that the northern Andes were clearly the major site of early speciation within *Tangara*, but that subsequent dispersal into other Neotropical regions increased diversity in the group. For example, dispersal followed by speciation occurred in two Amazonian groups. Repeated dispersals southward in the central Andes were followed by speciation, which similarly took place within a lower Central American group (Chiriquí–Darién, in Panama) and in two Atlantic Forest groups. One modern-day Atlantic Forest group, which includes the Green-headed Tanager (*Tangara seledon*), Seven-colored Tanager (*Tangara fastuosa*), Brassy-breasted Tanager (*Tangara desmaresti*) and Red-necked Tanager (*Tangara cyanocephala*), represents an assemblage of closely related species that is believed to have arisen from an early ancestor in the Atlantic region, and not from repeated colonization into the area from the outside. Although many similar speciation events occurred outside the northern Andes, this region has continued to be a source of such events, including a relatively modern species group that includes the Golden-eared Tanager (*Tangara chrysotis*), Saffron-crowned Tanager (*Tangara xanthocephala*), Flame-faced Tanager (*Tangara parzudakii*), Blue-whiskered Tanager (*Tangara johannae*), Golden Tanager (*Tangara arthus*), Silver-throated Tanager and Emerald Tanager, these last two having subsequently spread into Central America, and the Green-and-gold Tanager (*Tangara schrankii*), which has subsequently spread across Amazonia.

Molecular studies have not, to date, reliably identified a sister-taxon to *Tangara*, although the genus is part of a larger monophyletic clade that includes a group of "core" tanagers and numerous related tanager genera. Thus, the closest living relatives of *Tangara* remain uncertain. Also of interest in the Burns and Naoki study was the repudiation of the long-standing assumption that *Chlorochrysa* is closely related to *Tangara*. On the basis of size and plumage similarities, *Chlorochrysa*, which includes three of the most brilliantly coloured of all tanagers, has been traditionally placed next to *Tangara* in linear sequences. Some taxonomists have suggested that *Chlorochrysa* be subsumed into *Tangara*, but none of the phylogenetic analyses has identified *Chlorochrysa* as being sister to *Tangara*. This is not particularly surprising, because the plumage of all three *Chlorochrysa* species differs in being exceptionally glossy and glistening, the tibio-tarsus and adjacent leg musculature are larger and heavier than those of *Tangara*, and the bill of all three is proportionately longer and thinner. Corresponding to these anatomical differences, the foraging behaviour of *Chlorochrysa*, which is acrobatic and frequently includes episodes of hanging upside-down, is decidedly unlike that of *Tangara*.

*The **Yellow-tufted Dacnis** is often treated as conspecific with the Black-faced Dacnis* (Dacnis lineata). *As well as being geographically separated, however, the two differ in plumage, particularly the bright yellow breast, belly and undertail-coverts of the Yellow-tufted, which are white on the Black-faced Dacnis, and the yellow pectoral tuft from which the Yellow-tufted Dacnis gets its name. Both species have yellow irides. The two races of Yellow-tufted Dacnis are themselves widely separated, the nominate being found in northern Colombia, and* aequatorialis *on the Pacific slope in western Ecuador.*

[*Dacnis egregia egregia*, Río Alicante, Maceo, Antioquia, Colombia. Photo: Rodrigo Gaviria]

Previous linear sequences of *Tangara*, based on non-molecular characters, have usually grouped the Paradise Tanager (*Tangara chilensis*) with the Green-headed Tanager and Seven-colored Tanager on grounds of plumage similarities, but this treatment was not supported by molecular data. These relationships suggest that the striking similarity in plumage of the Paradise and Seven-colored Tanagers is the result of convergence. In the studies made by Burns and Naoki, the Paradise Tanager appeared to be most closely related to the Opal-rumped Tanager (*Tangara velia*) and Opal-crowned Tanager (*Tangara callophrys*). On the other hand, the Seven-colored and Green-headed Tanagers belong to the monophyletic sister-clade that also contains the Red-necked and Brassy-breasted Tanagers, a grouping that receives some support from their coincident distributions in the Atlantic Forest of eastern Brazil.

Several species of *Tangara* exhibit marked geographical variation in plumage colour and sometimes also in plumage pattern, and well over 100 subspecies in the genus have been described on the basis of this variation. With this in mind, Burns and Naoki examined levels of cytochrome *b* intraspecific sequence divergence in *Tangara*. Numerous factors can affect levels of sequence divergence, and these sometimes vary widely, although most species show levels of variation at or below 1%. Species presenting levels of variation higher than this often are those for which subspecies are described. Burns and Naoki found that, for many *Tangara*, sequence variation was indeed about 1% or less. This was the case for individuals from one and the same population, for those from adjacent island populations, for individuals from the same slope of the Andes, and for individuals from nearby populations, for instance on the east Andean slope and the adjacent Amazonian lowlands. They noted that for two species, namely the Blue-necked Tanager (*Tangara cyanicollis*) and Beryl-spangled Tanager (*Tangara nigroviridis*), which had populations on both the east and the west slopes of the Andes, the amount of sequence divergence was somewhat higher, at respectively 1·8% and 1·0%, but still within the range typical for individuals of the same species.

Five species of *Tangara* studied by Burns and Naoki showed constantly higher levels of sequence variation than was expected. For three of these, the Metallic-green Tanager (*Tangara labradorides*), Golden Tanager and Bay-headed Tanager (*Tangara gyrola*), the Andes appear to act as a barrier to gene flow. Examples of Metallic-green Tanagers from western Ecuador differed from those in north-eastern Peru by 6·6%, the highest observed for any *Tangara* and well above the level of divergence found for other accepted species of *Tangara*. For example, the Paradise, Opal-rumped and Opal-crowned Tanagers occur sympatrically in part of Amazonia without interbreeding, but they differ from one another by an average sequence divergence of 3·9%. Burns and Naoki observed similarly high levels of divergence, 3·6%, between east and west Andean slope populations of Golden Tanagers, and even higher levels of 4·6% between populations of

Like Dacnis, Cyanerpes *species have brightly coloured legs. The **Red-legged Honeycreeper** is the largest in the genus, and its slender, pointed and decurved bill, an adaptation to nectar-eating, can be up to 25 mm long. Most of the species in this genus also have a long bill. The exception is the Short-billed Honeycreeper* (C. nitidus). *Its bill is just 10 mm long, with an almost straight lower mandible and the upper mandible only slightly decurved near the tip. Male Red-legged Honeycreepers are very unusual among tropical bird species in that the male has a post-breeding "eclipse" plumage resembling that of the female.*

[*Cyanerpes cyaneus holti*, Aracruz, Espírito Santo, Brazil. Photo: Edson Endrigo]

Bay-headed Tanagers east of the Andes and those in Central America. Levels of variation within each of these groups of Bay-headed Tanagers was much lower, at about 1%, an indication that Central American populations and those east of the Andes have been isolated for a long time but that gene flow has been maintained within each population. Two allopatric populations of Spotted Tanagers (*Tangara punctata*), one from the Andes and the other from Amazonia, exhibited a sequence divergence as high as 6·0%, and two allopatric populations of Turquoise Tanagers (*Tangara mexicana*), one in Amazonia and another isolated in south-eastern Brazil, showed 4·1% divergence. In both cases, the high level of divergence indicates a long history of separation.

Burns and Naoki also found that some currently recognized species are separated from their closest relatives by unusually low levels of sequence divergence. Notable were the Black-capped Tanager (*Tangara heinei*) and Straw-backed Tanager (*Tangara argyrofenges*), which had a divergence of as little as 0·4%, a level of differentiation typically observed only within species. An explanation of such minimal differentiation despite significant plumage differences and non-overlapping distributions requires investigation. A third species, the Silver-backed Tanager (*Tangara viridicollis*), is similarly only weakly differentiated, by no more than 1·7%, from the previous two and also has an allopatric distribution. In their investigations, Burns and Naoki turned up other species groups with low levels of sequence divergence, including the morphologically similar Burnished-buff, Scrub and Lesser Antillean Tanagers. This clade represents a recent speciation in *Tangara* estimated to have occurred about 800,000 years ago, near the beginning of the middle Pleistocene. Pairwise-sequence-divergence data for these three taxa revealed a difference of only 1·4%. The low level of differentiation in the Lesser Antillean Tanager is somewhat surprising given its isolation on Caribbean islands, but less so that in the Scrub and Burnished-buff Tanagers, which are locally sympatric in Colombia. Current sympatry, however, may be the result of human-engendered habitat alteration or natural overlap. More recently, the Green-capped Tanager (*Tangara meyerdeschauenseei*), a fourth similar species, was described from scrub in a small, isolated highland site in south-eastern Peru. Despite its similarity to the other three, sequence data indicated that it differed by 3·8%, and it appears to be sister to the group. These four species are similar in plumage pattern and colour, and all occur in open and semi-open habitats rather than forest. Another equally recent split involved two members of the genus *Bangsia*, namely the Moss-backed and Gold-ringed Tanagers, both confined to the Chocó–Pacific slope region.

The sequence-divergence data obtained by Burns and Naoki revealed also that some *Tangara* tanagers whose status as full species has been questioned in the past are well differentiated genetically from their closest relatives. The geographically isolated Spangle-cheeked Tanager of the Chiriquí Highlands, in Costa Rica and western Panama, and Green-cheeked Tanager of the Darién Highlands, in eastern Panama, were often treated as two geographically isolated populations of a single species because they are rather similar in their plumage colour and pattern. Sequence-divergence data indicated that the two differed by 6·9%, well above typical values found among reproductively isolated species. In another example, the Masked Tanager (*Tangara nigrocincta*), found east of the Andes, and the Golden-hooded Tanager (*Tangara larvata*), found west of the Andes and in Middle America, have sometimes been regarded as representing a single species because they have similar overall plumage patterns. Pairwise-sequence-divergence data for these two taxa, however, showed that they differed by 4·4%, indicating that the two are well differentiated. Perhaps surprisingly, the Golden-hooded Tanager was genetically closest to the Blue-necked Tanager, another "hooded" species of primarily montane distribution. The three taxa have sometimes been considered to form a superspecies.

Finally, the enigmatic Golden-collared Honeycreeper (*Chlorophanes pulcherrimus*) has sometimes been placed in a monotypic genus *Iridophanes* and sometimes in the genus *Tangara*. Some authors also have noted similarities between it and the Green Honeycreeper (*Chlorophanes spiza*). It differs from *Tangara* in bill shape and colour, in having red eyes, and in its feeding behaviour. The molecular phylogenies of Burns, Hackett and Klein showed that the species is not part of a monophyletic group with *Tangara*, but appears to be a sister-taxon to the genus *Chlorophanes*. These scientists recommended that "*Tangara pulcherrima*", as it was then known, be reassigned preferentially to the genus *Chlorophanes*, a reasonable taxonomic solution for this long-debated taxon.

Turning now to the Swallow Tanager, this unusual species has traditionally been placed in a monotypic genus because it is

The two Heterospingus *species are rather large, heavily built tanagers, with a long heavy beak hooked at the tip. The two have been considered conspecific, but have significant plumage differences. While both are predominantly black with a yellow rump and white pectoral tufts, the male* ***Scarlet-browed Tanager*** *has a white brow line broadening into a prominent and slightly raised scarlet tuft, which is lacking on the female. The sexes of the duller, more leaden-grey Sulphur-rumped Tanager* (H. rubrifrons) *are alike. Both species often move faster than the mixed-species flocks with which they frequently forage, but the Scarlet-browed Tanager may also move sluggishly or perch motionless and erect for short periods.*

[*Heterospingus xanthopygius berliozi*, Ecuador. Photo: Marc Guyt/AGAMI]

morphologically and behaviourally distinct. It differs from other tanagers in building cup-nests in horizontal cavities in banks and cliffs, in holes in trees and in man-made structures. The Swallow Tanager also has an unusual palatal structure, some distinctive skeletal features, exceptionally long wings, and a bill that is rather flat and is unusually wide basally. It is frequently found in variably sized single-species flocks and is migratory or nomadic. These distinctive features have, in the past, been cited by various taxonomists as justification for placing this unusual species in its own family, in a separate subfamily, or in a separate tribe. All of these earlier morphology-based studies seem to have missed the mark. Sibley and Ahlquist's data from DNA–DNA hybridization were the first to suggest that *Tersina* was a tanager, possibly a sister-taxon to *Tangara*, a remarkable finding not previously suspected. The cytochrome *b* data obtained by Burns strongly supported this result, indicating that *Tersina* was, indeed, a tanager, and not a sister to the rest of the family, and that it should be included with the tanagers. The remarkable suite of morphological differences between *Tersina* and other tanagers seemed not to translate into comparable genetic change, a situation very unlike that found in *Euphonia* and *Chlorophonia*. The amount of sequence divergence between *Tersina* and other tanagers was, in fact, similar to that between other genera of tanagers. As pointed out by Sibley, the numerous unusual morphological features of *Tersina* seem, instead, to be associated with its specialized feeding behaviour and have evolved much more rapidly than have corresponding changes in mtDNA. Burns found that cytochrome *b* gene data placed *Tersina* with the honeycreeper genera *Cyanerpes* and *Dacnis*, the three forming a monophyletic group with strong support. While the bill shapes of *Cyanerpes* and *Dacnis* differ markedly from that of *Tersina*, the three genera have similar plumage features, including sexually dimorphic plumages in which the males are blue and the females are greenish. The inference is that, while plumage features may be conservative and slow to change, bill shapes that facilitate feeding behaviour may be more plastic and more readily subject to rapid changes.

Early taxonomists placed a number of genera of small, nectar-feeding, New World songbirds in a separate family under the name Coerebidae. In 1951, in an examination based on the anatomy of nectar-feeders, W. Beecher argued that the genera *Diglossa*, *Cyanerpes*, *Chlorophanes*, *Iridophanes*, *Hemidacnis* (= *Dacnis*), *Euneornis*, *Xenodacnis* and *Oreomanes* were in reality nectar-adapted tanagers, with similarities the result of convergent adaptations for nectar-feeding. He also concluded that the three genera *Coereba*, *Conirostrum* and *Ateleodacnis*, the last later subsumed into *Conirostrum*, were in fact parulid warblers adapted for nectar-feeding. As a result of his study, he argued that the Coerebidae should be disbanded, and he recommended the placing of some honeycreeper genera in a tribe within Thraupidae and some genera in a separate tribe within Parulidae. His work was largely accepted in systematic arrangements, but decades later other taxonomists disagreed with his conclusions and split various genera among the families Coerebidae, Emberizidae and Thraupidae. More recently, Sibley and Ahlquist, who included only two of these genera, *Cyanerpes* and *Diglossa*, in their analyses of DNA–DNA hybridization, placed all former members of Coerebidae in a tribe Thraupini within a subfamily Emberizinae, which formed part of a greatly enlarged Fringillidae. The overall result has been little general agreement on the phylogenetic relationships of Neotropical honeycreepers.

Various molecular studies included some members of the Coerebidae, but Burns, Hackett and Klein, in 2003, were the first to include all ten members of the original Coerebidae, as well as numerous other genera, in a sequence study of the mitochondrial cytochrome *b* gene, thus greatly expanding the coverage of nectar-feeding species. Their analysis indicated that the Coerebidae did not form a monophyletic group. In addition, none of the former Coerebidae was closely related to the New World warblers, a finding that contradicts the early conclusions of Beecher and others but generally agrees with the DNA–DNA hybridization studies of Sibley and Ahlquist, who found that all of the Coerebidae were closely related to the species that they included in Thraupini, corresponding to the present-day Thraupidae. In addition, recent cytochrome *b* gene data indicate that many Neotropical honeycreepers form well-supported clades with certain tanagers and finches, the finches themselves being tanagers. The conclusion to be drawn from the lack of monophyly in Coerebidae is that recognition of this family is no longer warranted. The molecular data strongly suggest that nectarivory must have arisen multiple times during the long evolutionary history of tanagers and their allies. Furthermore, in general, species of Coerebidae

The three Hemithraupis *species are small, rather slender-billed and active tanagers, which in appearance and behaviour resemble New World warblers (Parulidae). In this genus, and the closely related* Chrysothlypis, *the upper mandible is dusky grey and the lower mandible pinkish or yellowish. The eleven subspecies of* ***Yellow-backed Tanager*** *currently recognized differ mainly in the intensity of their yellow colour and the extent of black mottling on the sides of the male. Some races are only weakly defined.*

[*Hemithraupis flavicollis insignis*,

Chrysothlypis *contains a single species, the* ***Black-and-yellow Tanager****. This genus is closely related to* Hemithraupis. *Unexpectedly, both of these genera of parulid-like tanagers are also closely related to the large, heavy-billed* Heterospingus. *Another genus containing a single warbler-like species,* Erythrothlypis, *has sometimes been subsumed into* Chrysothlypis. *The Scarlet-and-white Tanager* (E. salmoni) *is similar in size, body mass and bill shape to the Black-and-yellow Tanager, and both are sexually dimorphic, but they differ markedly in plumage colour and pattern, behaviour and food preferences.*

[*Chrysothlypis chrysomelas titanota*, Taús, Costa Rica. Photo: Julio E. Sánchez]

did not segregate into monophyletic groups based on bill shape or feeding behaviour. Instead, species with markedly different bill sizes and shapes often proved to be each other's closest relatives. In a striking example of this, the Bananaquit (*Coereba flaveola*), a species with a thin, sharply pointed and slightly decurved bill, appears to be the sister-taxon of the Yellow-faced Grassquit (*Tiaris olivaceus*), a species with a thick, stubby and conical bill and currently placed in Emberizidae.

Two nectar-feeding members of the former Coerebidae, the Bananaquit and the Orangequit (*Euneornis campestris*), the latter confined to Jamaica, belong to a clade of species that build covered nests. This clade includes also some seed-eating genera of "Darwin's finches" and species in the genus *Tiaris*, all currently placed in Emberizidae. The striking differences in bill morphology and feeding behaviour found within this group of closely related species have evidently taken place with little genetic divergence among the species. On the basis of these morphological differences, members of this clade have in the past been placed in three separate families.

Similarly, the systematic position of *Conirostrum* in relation to other taxa has had a confused history. In the past, authors have placed this genus variously in Coerebidae, Parulidae and Thraupidae. T. Schulenberg believed that *Conirostrum* was close to *Oreomanes* on the grounds of plumage colour and pattern, body shape, and the occurrence of hybridization between *Oreomanes* and the White-browed Conebill (*Conirostrum ferrugineiventre*). Recent molecular phylogenies support the contention that the two genera form a monophyletic group. The genus *Conirostrum* itself, however, is not monophyletic with respect to *Oreomanes*, and further work is awaited before the systematic status of *Conirostrum* can be more fully resolved.

Perhaps the best-known New World nectar-feeders are the flowerpiercers in the genus *Diglossa*. All members were originally described in this genus, but some species were at one time separated in *Diglossopis* on the basis of plumage characters, having overall blue plumage, with little or no sexual dimorphism, and a smooth, rather than scaled, forehead. *Diglossopis*, however, proved to be polyphyletic, with at least one member, the Indigo Flowerpiercer (*Diglossa indigotica*), more closely related to some *Diglossa* than to those placed in *Diglossopis*, and the latter genus is no longer recognized. Genetically, *Diglossa* is monophyletic and appears to form a large monophyletic clade with representatives of at least ten other genera, namely *Acanthidops*, *Catamenia*, *Conirostrum*, *Haplospiza*, *Idiopsar*, *Melanodera*, *Oreomanes*, *Phrygilus*, *Sicalis* and *Xenodacnis*. Some of these are also sister to *Diglossa*, although the exact membership of these sister-groups is not fully resolved. Among the 18 species of *Diglossa*, four superspecies groups were postulated some 40 years ago by F. Vuilleumier. These four, based on, respectively, *D. lafresnayii*, *D. carbonaria*, *D. baritula* and *D. albilatera*, have subsequently been supported by the molecular-genetic studies of Mauck and Burns,

In the past, authors have placed the genus Conirostrum *variously in Coerebidae (the former honeycreeper family) and Parulidae (the New World warblers), but molecular-genetic data indicate that it belongs in Thraupidae. The* ***White-browed Conebill*** *is generally found between 3000 m and 3600 m and in the vicinity of the tree-line, and five other members of the genus are also highland species. The four lowland* Conirostrum *species were originally placed in the genus* Ateleodacnis, *and some taxonomists argue that they should be returned to it, as they are morphologically distinct from the highland species.*

[*Conirostrum ferrugineiventre*, Cotapata National Park, La Paz, Bolivia. Photo: Daniel Alarcón]

Only one tanager species, the ***Giant Conebill****, is regularly found above the tree-line. It inhabits a unique* Polylepis *woodland that grows at elevations higher than the normal timber-line. The monotypic genus* Oreomanes *is sometimes subsumed in* Conirostrum*, and the Giant Conebill has hybridized with the White-browed Conebill* (C. ferrugineiventre)*, shown in the previous picture, suggesting a close relationship. No subspecies of Giant Conebill are recognized here; bill length increases and plumage becomes paler from north to south, but facial plumage varies independently of geographical location, often within a single population.*

[*Oreomanes fraseri*, Papallacta, Ecuador. Photo: Greg & Yvonne Dean/ WorldWildlifeImages.com]

although the amount of interspecific variation within the *carbonaria* superspecies was very low and comparable to that usually found within a single species.

On the basis of a biogeographical reconstruction of the ancestors of all flowerpiercers, the Andes are inferred to be the region where the group originated. Specifically, the northern portion or the northern and central portions of the Andes are the most important regions. This is reflected in modern distributions, many species having ranges that include the northern Andes. Events such as uplift and other tectonic activity, climate change and climatic cycles are all likely to have played roles in the diversification of the family, although the linking of specific events or cycles, except in the broadest terms, remains an elusive goal of molecular biogeographers. The timing of speciation events for flowerpiercers spans several million years, dating back as early as 15 million years and as recently as about 400,000 years. Of approximately 17 speciation events inferred for flowerpiercers, the five most recent occurred during the Pleistocene, between about 1·5 million and 0·4 million years ago; five more speciation events can be placed within the Pliocene, roughly between 5 million and 2 million years ago; and the remaining seven date from the early and middle Miocene, stretching back to between 15 million and 6 million years ago. Historically, both the central and the northern portions of the Andes reached about half of their present elevation some 10 million years ago, by which time *Diglossa* speciation was already under way. The central portion of the Andes underwent a final rapid uplift, reaching its present height between about 10 million and 6 million years ago, somewhat before the last main uplift of the northern end of the Andes, which took place between about 7 million and 4 million years ago. Some parts of the northern Andes experienced a rapid final uplift as recently as 5 million to 2 million years ago. These dates correspond well with a variety of *Diglossa* speciation events. Such events, however, have continued to take place even more recently, several having occurred during the late Pleistocene, when glacial episodes were prominent. In particular, during the last 800,000 years, glacial episodes were extreme and are believed to have been important in influencing speciation events. The *carbonaria* superspecies is an example of a recent *Diglossa* speciation event that was driven by Pleistocene glaciation cycles; the earliest speciation event for this group is dated to about 475,000 years ago (with a margin of error dating to between 785,000 and 207,000 years ago). It represents one of a growing number of examples now identified in which rapid plumage divergence has not been accompanied by similar rapid mtDNA divergence. In the *carbonaria* superspecies, sequence divergence is equal to or even less than that found in many species.

While most of these speciation events occurred within the Andes, there were two dispersal events out of the Andes, one to Middle America, either to the Madrean Highlands or to the Chiriquí-Darién Highlands, and another to the tepui highlands of southern Venezuela. The dispersal into Middle America is inferred to have occurred between about 12 million and 5 million years ago, which is considerably earlier than the final closure of the Panamanian land-bridge connection between Central and South America. Molecular studies of the distribution of species before and after the land-bridge closure, however, are at present too few for any statements regarding general patterns to be made. To date, evidence suggests only that some species crossed prior to closure, and others at or after closure. The analysis by Mauck and Burns indicates a dispersal from the Andes to the tepuis, but does not show dispersal movements away from the tepuis. The dispersal of a *Diglossa* ancestor to the tepuis occurred between about 10 million and 6 million years ago, and the two species presently found in the tepuis were shown to have separated about 6 million years ago. Interestingly, the two exhibit only relatively weak evidence of monophyly, and Mauck and Burns leave open the possibility of a second independent dispersal from the Andes to the tepuis. The tepuis represent an extremely old rock formation, and erosion has been under way since the Cretaceous period. It is uncertain, however, to what extent the tepuis have changed since the first inferred ancestral flowerpiercer reached the area, and it is equally uncertain if the tepuis were significantly more extensive at this point in history and if this may have enabled successful dispersal and colonization. If the calculations of Mauck and Burns are reasonable, it is clear that the important glacial episodes of the Pleistocene occurred far too late to explain flowerpiercer dispersal to the tepuis.

While a strongly hooked bill is regarded as a characteristic morphological feature of the genus *Diglossa*, the size of the bill hook, as well as the size of the bill, varies considerably in modern *Diglossa*. The longest bill and the smallest hook in relation to

bill size are found in the Masked Flowerpiercer (*Diglossa cyanea*), and the smallest bill and proportionately the largest hook are possessed by the Slaty (*Diglossa plumbea*) and Cinnamon-bellied Flowerpiercers (*Diglossa baritula*), two Middle American species which are also among the smallest flowerpiercers. Mauck and Burns postulated an initial divergence in flowerpiercer evolution in which bill and hook sizes began to diverge, but they argued that the change in bill-and-hook size has not been a simple progression. Instead, combinations of bill sizes and hook sizes have continued to evolve and change through history. Within the phylogeny of the genus *Diglossa*, a large bill hook and a small bill hook evolved many times in lineages not closely related to each other, indicating that bill morphology is malleable to evolutionary pressures. The diversity in hook size, as well as in bill size and length, has allowed up to about six species to co-exist locally at some Andean sites. Where multiple species of *Diglossa* are sympatric, bill and hook sizes differ markedly, resulting in distinctive partitioning of food resources. Overlapping species also typically differ in micro-habitat choices and in degrees of sociality, among other things.

An examination of phylogenetic-tree branches indicates that nectar-feeding lineages in tanagers arose three times and possibly more. One lineage includes *Dacnis* and *Cyanerpes*, a second includes *Diglossa*, *Oreomanes* and *Xenodacnis*, and a third lineage involved *Chlorophanes* and possibly others. *Coereba* and *Euneornis* may involve yet another lineage. In the second lineage, a close relationship among the three genera may not be easily predicted on the basis solely of bill morphology and feeding adaptations. These three genera share some plumage similarities, but *Diglossa* species, at least in the case of the smaller ones, are primarily nectar-feeders with a hooked bill and with a few species partially adapted for feeding on small fruits, whereas *Oreomanes* is a bark-searching insect-eater with a thin sharply pointed bill, and *Xenodacnis* is a partial nectarivore with a sharply pointed bill. The three differ remarkably in bill morphology. The possession of similar plumage patterns but different bill shapes, as seen in these three genera, mirrors a similar pattern found in *Tersina*, *Dacnis* and *Cyanerpes*.

Galapagos finches, often referred to as Darwin's finches, have long been acclaimed for their importance in evolutionary theory, but their origin has only recently been examined by means of rigorous phylogenetic procedures. An analysis of mitochondrial DNA from the cytochrome *b* gene indicated that the group is monophyletic, and presented as its sister a clade of six Caribbean species, comprising four of *Tiaris*, and one each of *Loxigilla* and *Melanospiza*, all of which build domed nests and all of which are closely aligned with tanagers. At the same time, of 13 species identified as closely related to Darwin's finches eleven proved to occur in the Caribbean, including eight island endemics; together with Darwin's finches, they form a domed-nest clade. This evidence from nest architecture, as well as genetic data, weakens the long-held view that a South American ancestor was the source of the Galapagos birds. Additionally, the taxa in the Caribbean group display remarkably low genetic diversity, suggesting that, instead of being relics of formerly widespread ancestors, or birds that managed to arrive from a variety of adjacent areas, they represent a group of closely related and recently evolved taxa. They may have originated more recently than other taxa in South America, and they may have been more successful in colonizing newer islands, as well as having a greater likelihood of dispersing. Notwithstanding the recent findings from molecular-genetic analyses, all of these finches are currently included within the family Emberizidae (see page 428), although their true placement appears to be in Thraupidae.

Other recent molecular work places several high-Andean and Patagonian genera, all at present included in Emberizidae, with Thraupidae. These genera, *Phrygilus*, *Diuca*, *Haplospiza*, *Poospiza*, *Sicalis*, *Embernagra* and *Catamenia*, spring from relatively recent radiations into open, largely treeless habitats above the tree-line in the Andes and on the Patagonian steppes. The addition of these genera increases the diversity of habitats which tanagers are known to occupy, and represents a marked expansion from earlier, more traditional family classifications with species predominantly in humid forest habitats and few or none in xeric regions and treeless zones. Now, the habitats range to xeric scrub in the Galapagos, high-elevation grasslands in the Andes and arid grassland and shrub-steppe in Patagonia.

Although *Euphonia* and *Chlorophonia* have long been regarded as tanagers, all molecular-genetic studies have suggested that the two genera form a monophyletic clade outside the Thraupidae. Importantly, these two genera differ from tanagers in several other significant ways, including the possession of a specialized diges-

Recent molecular-genetic data indicate that the ***Tit-like Dacnis****, with its thin, sharply pointed bill adapted to insectivory and nectaring, is closest to the flowerpiercers of the genus* Diglossa*, but also to the finch-billed and seed-eating* Haplospiza *and* Catamenia*, and the bamboo specialist* Acanthidops*. The last three genera are currently placed in Emberizidae. While the male Tit-like Dacnis is essentially all dark blue, the throat and underparts of the female are a deep cinnamon-buff, colouring she shares with* Oreomanes*, some* Conirostrum *and some* Diglossa*. Other common colours of species in these genera include blues and greys, supporting the idea of a close relationship among them.*

[*Xenodacnis parina bella*, Ecuador. Photo: Glenn Bartley]

The flowerpiercers (Diglossa) *have a downward-curved hook on the upper mandible of the beak that enables them to rob flowers of nectar without pollinating them. The upper mandible is used to hold the corolla of a flower while the bird pierces the flower with its lower mandible. The size of the hook, as well as the size of the bill, varies considerably. The* ***Moustached Flowerpiercer*** *(above) is a large flowerpiercer with a bill proportionately longer, straighter and less obviously hooked than that of smaller members of the genus. The longest bill and the smallest hook in relation to bill size are found in the* **Masked Flowerpiercer** *(below). The smallest bills and proportionately the largest hooks are possessed by the Slaty Flowerpiercer* (D. plumbea) *and the Cinnamon-bellied Flowerpiercer* (D. baritula), *which are also among the smallest flowerpiercers. A relatively large hook and a relatively small hook evolved multiple times in unrelated lineages. Up to six species of flowerpiercer can co-exist locally at some Andean sites, the differences in bill and hook sizes enabling food resources to be partitioned. Flowerpiercers originated in the Andes, with a single dispersal event from the northern Andes to Central America, and another single dispersal event from the northern Andes to the tepuis. The Masked Flowerpiercer, along with the Deep-blue* (D. glauca), *Bluish* (D. caerulescens) *and Indigo Flowerpiercers* (D. indigotica), *has sometimes been placed in a separate genus,* Diglossopis, *on grounds of some important anatomical features. Recent molecular-genetic data, however, indicate that these four species do not form a monophyletic group.*

Below: *Diglossa cyanea cyanea*, Ecuador. Photo: Tui de Roy/ Roving Tortoise Photos]

Molecular-genetic data indicate that the ***Plushcap*** *probably belongs among the tanagers. Its relationships are uncertain, and it has also been placed in a subfamily of Emberizidae (buntings and New World sparrows), and in its own single-genus, single-species family, Catamblyrhynchidae. Its stubby bill is thick and swollen. Like* Hemispingus *tanagers, the Plushcap is closely associated with dense undergrowth in montane forest, mainly where* Chusquea *bamboo is present, and its song is reminiscent of that of several* Hemispingus *species.*

[*Catamblyrhynchus diadema diadema*, Tapichalaca Biological Reserve, Zamora-Chinchipe, Ecuador. Photo: Doug Wechsler/ VIREO]

tive track and the building of a covered nest. In both, the stomach is reduced to little more than a thickening of the digestive track and is adapted for digesting soft fruit pulp but not the much harder and potentially toxic accompanying seeds, and for quickly passing seeds and other indigestible material through the gut. The covered nest also sets these two genera apart from all except a tiny fraction of tanagers, and nest architecture appears to be a conservative genetic behaviour that is not likely to change over short periods of time. Both genera are also remarkably similar in skeletal morphology. Cytochrome *b* molecular data suggest that *Chlorophonia* and *Euphonia* form a distinctive, monophyletic clade well separated from all Thraupidae, as well as from Parulidae. Genetic distances between tanagers and *Chlorophonia* and *Euphonia* were found to be, in fact, greater than those between parulid warblers and tanagers. Recent work suggests that the two genera are closest to Fringillidae and should not be included within Thraupidae.

Again on the basis of cytochrome *b* data, Burns found that the three Caribbean genera *Spindalis*, *Nesospingus* and *Phaenicophilus*, all traditionally placed in Thraupidae, formed a paraphyletic basal grouping compared with other tanagers and, thus, were not closely related to tanagers. The close relationship of these three genera to one another was not surprising, but the close relationship of *Chlorospingus* to these three was unexpected. Previous linear classifications had not identified the four genera as being closely affiliated, in part because *Chlorospingus* is continental and montane, whereas the other three genera are Caribbean and occur in both lowland and highland areas. Nevertheless, a few plumage characters are shared by all four genera. For example, the plumage of all four is olive-green to olive-brown and yellowish. In addition, *Spindalis* and *Phaenicophilus* have the head distinctively striped black and white, a pattern mirrored in the Sooty-capped Bush-tanager (*Chlorospingus pileatus*) in Costa Rica, and to a lesser degree in the form of postocular spots and marks in several other *Chlorospingus*. Female and juvenile plumage similarities in some of the Caribbean genera also have been noted.

In contrast to numerous plumage similarities between *Chlorospingus* and the three Caribbean genera, the sizes of these two groups differ dramatically. Average weights for *Spindalis*, *Phaenicophilus* and *Nesospingus*, respectively 31·2 g, 29 g and 36 g, are about 50% larger than that for *Chlorospingus*, which is 21·7 g. While all species of *Chlorospingus* are confined to montane regions from Mexico south through the Andes to northern Argentina, *Spindalis*, *Phaenicophilus* and *Nesospingus* are largely restricted to islands, where their larger sizes may have evolved for a variety of reasons associated with island distributions, including absence of predators, food resources and lack of competition.

Over and above the relationship with these three Caribbean genera, recent evidence now suggests that *Chlorospingus* may be closest to some New World sparrows of the genus *Arremonops*. The group of taxa habitually combined as the Common Bush-tanager (*Chlorospingus ophthalmicus*) is by far the most complex in the genus and is the one most in need of taxonomic revision. Five distinct clades have been identified within the Mexican population alone. Moreover, several Panamanian and Andean groups have been identified that may represent distinct species, including birds from parts of Venezuela and adjacent northern Colombia, such as the subspecies *venezuelensis*, *eminens*, *exitelus*, *flavopectus*, *trudis* and others, which are characterized by the fact that they have a blackish or grey, not brownish, crown, an essentially unspotted white throat, and no white postocular spot, and the dark-eyed form *argentinus* and others from the far southern portion of this group's range.

Chat-tanagers (*Calyptophilus*) have long been regarded as thraupids, but the phylogenetic relationships of the various Hispaniolan populations of this genus to tanagers or other groups remain ambiguous. Recent molecular investigation based on sequences of mitochondrial ND2 DNA and three nuclear intron loci has provided support in resolving the taxonomic status of the seven extant populations of *Calyptophilus*. Separated montane populations may have differentiated prior to the joining of the two paleo-islands that form present-day Hispaniola. These populations, however, do not have a long history of isolation, and the question is that of whether they represent one large polymorphic population or two taxonomic species.

Finally, there is the matter of the true affiliations of the genera *Piranga*, *Habia* and *Chlorothraupis*. Although *Piranga* species are often regarded as "classic" tanagers, several independent molecular studies have convincingly indicated that members of this genus are not thraupids and more properly belong among the cardinalids, where they likely are sister to a well-supported clade that includes *Cardinalis*, *Caryothraustes*, *Periporphyrus* and *Rhodospingus*, almost all of which are characterized by the possession of a black mask, though this is quite

Another species of uncertain affinities, the ***Black-backed Bush-tanager*** *is regarded by some authorities as belonging in the family Emberizidae, possibly being closest to the* Atlapetes *brush-finches. Others see it as closest to the* Chlorospingus *bush-tanagers, and molecular-genetic data indicate that it probably does belong in Thraupidae. It is a high-elevation species, found in dense, wet forest and in patches of stunted and* Polylepis*-dominated woodland up to the tree-line. It has been recorded as high as 4000 m in Ecuador.*

[*Urothraupis stolzmanni*, Los Nevados National Park, Colombia.
Photo: Pete Morris]

small on some species. The eleven species of *Piranga* are sexually dichromatic, with males brightly coloured and typically having red in the plumage. Three *Piranga* also have a small black mask, although the group appears to have diverged quite early from its sister-group, and the mask, as a morphological character, may have been lost by an ancestor of the remaining members of the genus. The geographical distribution of *Piranga* is centred on Mexico and Central America, and three species are endemic there. *Piranga* is composed of a clade containing the Red-hooded Tanager (*Piranga rubriceps*), White-winged Tanager (*Piranga leucoptera*) and Red-headed Tanager (*Piranga erythrocephala*), and another clade containing the Summer (*Piranga rubra*), Western (*Piranga ludoviciana*), Scarlet (*Piranga olivacea*) and Flame-colored Tanagers (*Piranga bidentata*) and the Northern (*Piranga hepatica*), Highland (*Piranga lutea*) and Lowland Hepatic-tanagers (*Piranga flava*). The placement of one species, the Rose-throated Tanager (*Piranga roseogularis*), currently remains uncertain.

Piranga, along with *Habia* and *Chlorothraupis*, forms a large, well-supported clade that seems to be unrelated to the tanagers and clusters within "Cardinalini". The placing of these genera within Cardinalini differs from all previous historical and modern taxonomies. Additionally, the ant-tanagers forming the genus *Habia* appear to be a polyphyletic group also unrelated to tanagers, with the Red-crowned Ant-tanager sister to all *Chlorothraupis*. This polyphyly is evident also in the plumages of ant-tanagers, some of which exhibit marked sexual dichromatism, with males mostly red and females, such as the female Red-crowned Ant-tanager, having dull yellowish and olive plumage much like monochromatic *Chlorothraupis*. In some other species of ant-tanager, females do not differ greatly from males, but are duller.

Morphological Aspects

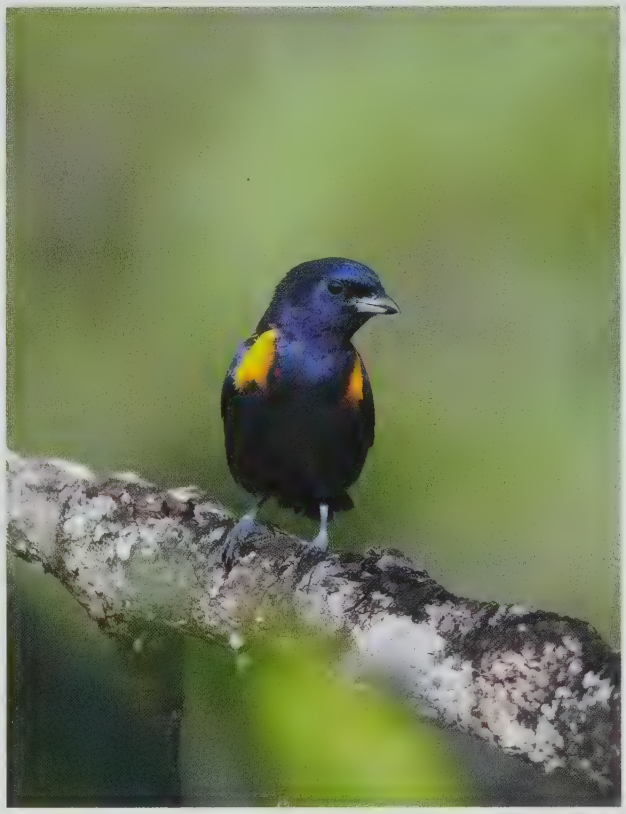
True Thraupidae comprise a morphologically fairly diverse group of species that are not easily summarized in broad generalizations. Those known to be true tanagers (see Systematics) range from small, quick species, such as the *Conirostrum* conebills and *Diglossa* flowerpiercers, to larger and more sluggish mountain-tanagers in *Buthraupis*. The family, broadly, comprises part of a larger group of nine-primaried songbirds, so designated because, with the exception of a few vireos, they have the outermost, or tenth, primary of the wing tiny and concealed. All of the nine-primaried songbirds, apart from some emberizine finches, are found in the New World. Genetically, tanagers as a group are aligned within this nine-primaried oscine assemblage, but taxonomists have found few, if any, morphological features that are common to all members of the family. Sclater, writing in 1886, noted that many tanagers could be characterized by the presence of a small notch near the end of the upper mandible. The notch was prominent in some species but scarcely apparent in others, and as a diagnostic feature it was ultimately of little value. Modern DNA-sampling has now shown that some genera in which the notch is prominent are evidently unrelated to the Thraupidae. Attempts to relate diet, bill shape, jaw musculature, and colour, pattern and texture of the plumage proved equally frustrating in defining the family. Failing to find morphological clues, Storer, in 1969, concluded "I believe that... the traditional lines between the tanagers and the finches and the tanagers and wood warblers will prove untenable, and different alignments between the genera will better show phylogenetic relationships." His statement proved remarkably prescient.

Ultimately, a complete reorganization of the tanager family will surely follow further DNA-sampling, something that continues to the present and is radically altering our concept of this and other avian families. What has emerged so far is a collection of species that, because of diverse plumages and remarkable variations in bill size, shape and function, may at first glance appear to have little in common with one another. No single morphological trait, or combination of physical traits, seems to define a tanager other than shared genetic ancestry. Yet, even as the family is reorganized, with several well-known and long-standing genera now being removed to other families, and numerous emberizid genera and a few cardinalids entering Thraupidae, one feature that does come to mind whenever one thinks of tanagers is the remarkable evolution of colourful plumages within the family. Bright colours are not unique to tanagers, of course, nor are all tanagers colourful. Some are, in fact, rather plain or have a modest plumage pattern, and that seems particularly true of numerous emberizid genera recently found to be genetically allied with the thraupids. Nevertheless, some of the largest and best-known genera of tanagers, including *Tangara*, *Buthraupis*,

The euphonias are strongly sexually dimorphic, the males being brilliantly coloured and the females mostly olive above and yellow beneath, as illustrated by this ***Violaceous Euphonia*** *pair. This species is a small member of its genus, but with a relatively heavy bill. Although for long regarded as tanagers, molecular-genetic data, morphology and some aspects of behaviour all suggest that the 27 species in the genus* Euphonia *belong elsewhere. Along with* Chlorophonia, *to which they seem most closely related,* Euphonia *species have a very specialized digestive tract and build covered nests.*

[*Euphonia violacea aurantiicollis*, REGUA Nature Reserve, Guapiaçu, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Bangsia, *Anisognathus*, *Iridosornis*, *Cyanerpes* and *Dacnis*, are extraordinarily colourful, and can be counted among the most colourful of all passerine birds. It is surely this feature that comes to mind when amateur and expert alike think of tanagers.



Pre-eminent with regard to colour are members of the genus *Tangara*, the 49 species of which represent not only the largest generic grouping of birds in South America, but also arguably the most colourful. This genus is set to become even larger with the addition of species formerly placed in *Thraupis*. In size and body shape *Tangara* tanagers are remarkably uniform, being small arboreal species with a stout, moderate-length bill, a tail of average length, and a rather small but sturdy and compact body. None has elongated plumes or tufts or an erectile crest or other unusual adornments, although one species, the Golden-eared Tanager, is capable of expanding its elongated ear-coverts. What *Tangara* do possess, collectively, is a breathtaking diversity of complex, often quilt-like colour patterns almost unrivalled in the avian world. In some, such as the Bay-headed Tanager and Blue-and-black Tanager (*Tangara vassorii*), the pattern is colourful but simple, while in others, such as the Green-and-gold Tanager, Saffron-crowned Tanager and Red-necked Tanager, the pattern is both colourful and complex. Although colour is perhaps the defining feature of the genus, a few of the species are notably plain. Dullest of the group is the aptly named Plain-colored Tanager (*Tangara inornata*), but the Scrub Tanager, Green-capped Tanager and a few other "minimalists" present relatively little bright colour or contrasting pattern in the plumage.

Within *Tangara*, every colour combination and hue of the rainbow is represented, and in a few species, most notably the Seven-colored Tanager and Paradise Tanager, almost every colour in the spectrum can be found on bold display. In others, the patterns are among the most complex to be found in nature, combining streaking, spotting, sharp geometric shapes, as typified by the trapezoidal black neck patch of the Golden Tanager, and bold but intricate, almost tapestry-like patterns on the mantle, as illustrated by the Emerald Tanager and Golden-eared Tanager. If *Tangara* tanagers are remarkable for their exceedingly colourful and complex patterns, their mostly higher-elevation and larger-bodied counterparts, the mountain-tanagers and allies, including *Buthraupis*, *Anisognathus*, *Chlorornis*, *Dubusia*, *Delothraupis*, *Iridosornis* and *Bangsia*, are almost equally colourful, although generally garbed in less complex colour patterns. Predominant in several of these genera are large block-like patches of yellow, blue, gold, rufous, moss-green and black. One species, the Scarlet-bellied Mountain-tanager (*Anisognathus igniventris*), combines red, sky-blue and black in a memorable display of colour, especially obvious when seen in flight.

Colour reaches its greatest intensity and saturation in the genus *Ramphocelus*, a group of mostly lowland tanagers in which males exhibit some of the most intense, velvety blacks, glistening reds and dark maroon-reds to be found in nature. In most species of *Ramphocelus* these intense reds and blacks are further enhanced by an enlarged, gleaming white lower mandible that is swollen and especially prominent at its proximal end. Numerous other genera of tanagers are brilliantly coloured or present arresting combinations of black and white, red, tawny or yellow in a seemingly endless array of patterns.

The displays of tanagers are, in general, not well documented except for the studies by Moynihan of two species of *Ramphocelus* and two *Chlorospingus* bush-tanagers (see General Habits). Among those described, however, display is rather unremarkable, and it does not appear that the brilliant colours and patterns that characterize the family have evolved primarily for display purposes in the way in which they have with manakins (Pipridae) and cotingas (Cotingidae) and various Old World groups. Several tanagers in the genus *Tachyphonus* puff out bold white shoulder epaulets in aggressive postures towards conspecifics. Other species of *Tachyphonus* may expand their white or yellow pectoral tufts and white or tawny flank-tufts in striking sexual displays towards females. Several *Tachyphonus* tanagers have concealed and colourful crown patches that can be erected, and others have flat, semi-concealed crests that range from flame-red to yellow, or combinations of both, and these can, at times, be expanded dramatically. These bold displays of colour by *Tachyphonus* are visible primarily in sexual and aggressive displays. At other times, the colourful crown and underwing patches are scarcely noticeable. The only true tanager with a more or less permanent crest is the Grey-headed Tanager, although even with this species the crest is not especially large and is often held semi-depressed. Ant-tanagers, which are now believed to be much more closely allied to cardinalids than to the true tanagers (see Systematics), have a flat crest which can be erected, and both Crested (*Habia cristata*) and Sooty Ant-tanagers (*Habia gutturalis*) sport a well-developed, contrasting red crest.

Many male euphonias share a basic plumage of blue upperparts and yellow underparts, with or without a yellow forehead and crown. Similarly patterned species often replace one another geographically and may form superspecies. The ***Purple-throated Euphonia*** *(above left), a small euphonia with a yellow forehead, glossy blue-black back and bright yellow underparts, may form a superspecies with the Scrub* (E. affinis), *Yellow-crowned* (E. luteicapilla) *and Trinidad Euphonias* (E. trinitatis). *There are greater differences between the* ***Golden-sided Euphonia*** *(above right), with its almost wholly dark glossy blue plumage, and the Rufous-bellied* (E. rufiventris) *and Chestnut-bellied Euphonias* (E. pectoralis), *but all share the golden-yellow pectoral patch. The* ***Blue-hooded Euphonia*** *(below left) forms a superspecies with the Golden-rumped* (E. cyanocephala) *and Antillean Euphonias* (E. musica). *A few species, such a the* ***Olive-backed Euphonia*** *(below right), differ from the majority in having drab female-type plumage.*

True tanagers exhibit a wide range of bill shapes, perhaps as diverse as in any Neotropical family, including the Furnariidae, although a majority of tanagers are equipped with a typical, multipurpose bill of average length and stoutness. This "average" bill, which is useful for capturing insects and for mashing or gulping fruits and small berries, is by far the most common bill type in the family. It characterizes many tanager genera, including *Schistochlamys*, *Cissopis*, *Neothraupis*, *Conothraupis*, *Lamprospiza*, *Tachyphonus*, *Ramphocelus*, *Thraupis*, *Bangsia*, *Buthraupis*, *Anisognathus*, *Iridosornis*, *Delothraupis*, *Tangara* and others. In some of these genera, in particular *Ramphocelus*, the bill is, on average, slightly thicker, and is then associated with the habit of mashing larger fruits and berries before consuming them. In others, such as high-elevation mountain-tanagers, which eat many small berries and also search for insects on mossy branches, the bill is stout but rather short for the size of the bird, and also may be associated with the practice of mashing fruit. Across the many species of *Tangara*, bill size and thickness represent, perhaps, an average for the family, being not too thick or too thin, and not too long or too short, a "goldilocks" compromise well suited for grasp-

Like the euphonias, to which they are most closely related, the five Chlorophonia *species almost certainly belong in the finch family Fringillidae. Chlorophonias are stockier than euphonias and the adult males are predominantly light green. They are less sexually dimorphic than the euphonias. The female* ***Blue-crowned Chlorophonia****, for example, is of a similar glistening emerald-green to that of the male, and has a similar turquoise-blue crown patch and narrow nuchal band of light blue, though both areas of blue are less extensive than on the male.*

[*Chlorophonia occipitalis*, Photo: Roland Seitre]

ing and gulping and sometimes also mashing small berries, as well as for capturing small insect prey on a wide variety of substrates, ranging from foliage and slender bare twigs to large bare or moss-covered branches.

Members of the small genus *Chlorochrysa* closely resemble *Tangara* in size and shape and in possessing brilliant colours, although the colours of *Chlorochrysa* are predominantly rich emerald-greens and sapphire-blues that glisten, satin-like, in the sun. The bill is similar to that of most *Tangara*, with which they commonly associate, but is always thinner. Like *Tangara*, they eat both small berries and insects, but they include more insects and fewer fruit items in their diet than *Tangara* tanagers. The thinner bill is well adapted for capturing insects. Where *Chlorochrysa* differ most dramatically from *Tangara*, as well as from other tanagers, is in leg structure. *Chlorochrysa* species search for insects by hanging from the undersides of leaves or leaf clusters, flying from one terminal clump to the next, or sprinting quickly along mossy limbs and out to terminal foliage, where they can be seen as they hang down or cling, belly up, beneath leaves, a form of behaviour rarely observed for any *Tangara*. Not surprisingly, in *Chlorochrysa* the feet and tarsometatarsus, as well as the leg musculature surrounding the tibiotarsus, are unusually strong and heavy relative to overall size, indeed among the most robust of any member of the family. Recent genetic data also indicate that, despite superficial similarities in appearance and diet, *Chlorochrysa* are not particularly closely related to *Tangara*.

While there has been strong selection for a generalist bill shape among species that take a mixed diet of fruit and insects, those species having a diet biased towards insects or towards nectar exhibit greater specialization in bill shapes. Those which depend upon seeds or nectar show even more extreme modifications in bill shape. A small and proportionately thin bill is associated with the gleaning of surfaces such as leaves and twigs for insects and secondarily for small berries, and can be found in many species, including those in the genera *Chrysothlypis*, *Erythrothlypis*, *Cnemoscopus*, *Hemispingus*, *Pyrrhocoma* and *Hemithraupis*, all of which are small and active, eat relatively little fruit, though *Erythrothlypis* consumes many *Clusia* arils, and spend much time in searching for insect prey. Among insect-eating tanagers, the thinnest bills are possessed by species of *Conirostrum* and *Thlypopsis*, which are small, highly active birds that spend most of their time gleaning in foliage for insects and take relatively few berries. Tanagers in the genus *Dacnis* and *Chrysothlypis* are only slightly heavier-billed, and they supplement intensive searching and insect-gleaning in canopy foliage with feeding visits to trees and shrubs with small berries. At the other end of the bill-size spectrum are the shrike-tanagers in the genus *Lanio*, which possess a rather long, heavy and straight bill with a conspicuous hooked tip. Shrike-tanagers often take prey from bark or foliage in fast, aerial sweeps and dives or, from a perch, make quick strikes or pecks at foliage, often capturing relatively large prey, which they can subdue or control by means of the sharp bill hook.

Where bill shapes differ most dramatically from the generalist one found in so many tanagers is in the small-bodied species that include varying amounts of nectar, small fruits and tiny cryptic insects in their diets. A thin, sharp-pointed bill is associated with the taking of nectar and tiny insects from flowers and the gleaning of tiny insects from leaves and flowers and sometimes sallying short distances into the air, and is found in such genera as *Dacnis* and *Xenodacnis* and *Conirostrum*. A much longer but similarly thin, sharp and slightly decurved bill again is associated with gleaning and probing in flowers, and is found in *Chlorophanes*; the two species in this genus also include some fruit in the diet. A long, slender and dramatically decurved bill, found especially in males of the *Cyanerpes* honeycreepers, being only slightly shorter and less decurved in females, is associated with specialized ways of consuming fruit, insects and nectar. The long, decurved bill enables the honeycreeper to reach into the narrow cracks of ripening arillate fruit husks and extract the rich arils before larger-billed birds can reach them, and these honeycreepers use the long bill also to grasp tiny insects hidden in cracks in bark and twigs and in vines.

A short, wide bill shaped almost like that of a swallow (Hirundinidae) is found on the Swallow Tanager, an enigmatic species that, at times, captures flying insect prey in aerial sallies in the open, as well as within tree canopies. The Swallow Tanager's bill is unique among tanagers, but does not represent the most extreme modification within the family. The most highly modified bill morphology in Thraupidae can be seen in the flowerpiercers in the genus *Diglossa*, which have both the upper and the lower mandibles slightly upturned and with a sharp hook at the tip of the upper mandible. In addition, the lower mandible is short and sharply pointed, and the tongue, with an inverted

Sole member of the genus Nesospingus*, the* ***Puerto Rican Tanager*** *is a drab, stout-billed island endemic. When first described, this species was tentatively included in the bush-tanager genus* Chlorospingus*, before being assigned to its own genus. Along with* Chlorospingus *and two other Caribbean island genera,* Spindalis *and the* Phaenicophilus *palm-tanagers,* Nesospingus *is part of a clade that is less closely related to other tanagers than to several New World warbler (Parulidae) genera, including* Dendroica, Basileuterus *and* Vermivora*. Average weights for the three island genera are around 50% greater than for* Chlorospingus.

[*Nesospingus speculiferus*, Puerto Rico. Photo: Adrian & Jane Binns/ VIREO]

Nine species of Chlorospingus *are recognized here, but relationships within the genus urgently require study. The race* olivaceiceps *of the* ***Ashy-throated Bush-tanager*** *(left) may represent a separate species, and so may the Central American race,* hypophaeus, *of the* ***Yellow-throated Bush-tanager*** *(right). Of 26 races of the Common Bush-tanager* (C. ophthalmicus) *currently recognized, some are at least as distinct as some taxa in the genus that are regarded as full species.*

[Left: *Chlorospingus canigularis canigularis*, Chicaque, Colombia. Photo:Jussi Vakkala.

Right: *Chlorospingus flavigularis flavigularis*, Reserva Natural de las Aves Arrierito Antioqueño, Anorí, Antioquia, Colombia. Photo: Roland Seitre]

U-shape in cross-section, when pressed against the mandible forms a tube that aids the bird in rapidly extracting nectar from tiny holes punched into the bases of the corollas of tubular flowers. This bill shape is most pronounced in the smaller species in the genus, especially the Cinnamon-bellied, Slaty, Rusty (*Diglossa sittoides*), Merida (*Diglossa gloriosa*) and White-sided Flowerpiercers (*Diglossa albilatera*), all of which obtain a substantial amount of their nourishment by piercing flowers. Flower-piercing behaviour and extreme bill modification are less evident in the three largest flowerpiercers, the Masked, Bluish (*Diglossa caerulescens*) and Moustached Flowerpiercers (*Diglossa mystacalis*), all of which have a bill that is straighter and with a less prominent hook at the tip.

Although recent molecular-genetic analyses suggest that *Chlorophonia* and *Euphonia* are most closely related to the fringillids (see Systematics), both genera have long been regarded as tanagers and both exhibit several interesting morphological adaptations related to their specialized feeding habits. Members of both genera feed predominantly on small, soft berries and supplement this diet with tiny insects and spiders (Araneae). They possess a short, stubby bill well suited for plucking and mashing small berries, biting pieces of larger fleshy fruit, plucking epiphytic mistletoe berries (Loranthaceae), pulling berries from fruiting spikes of Araceae plants, such as *Philodendron*, *Rhodospatha* and *Monstera*, and even hovering to pluck small berries. Members of both genera also have relatively short pliable digestive tubes with little more than a thickening where the stomach should be. Such "weak" stomachs easily digest soft fruit pulp, but do not digest or scar toxic seeds embedded in the fruit. Mistletoe berries, a case in point, are a favourite food of many species in both genera, but their seeds are highly toxic. The soft handling of these potentially lethal seeds leaves even the slimy protective layer around the seed intact as it quickly and harmlessly passes through the bird's gut. The sticky seeds are then voided intact in long strings that adhere to each other like strings of clear, miniature pearls and are wiped off against twigs or limb surfaces, where they remain stuck in potential germination sites.

In the last decade and a half, molecular-genetic studies have further suggested that *Chlorospingus*, *Piranga*, *Habia*, *Chlorothraupis* and *Mitrospingus* are unrelated to thraupids (see Systematics). Members of these genera have a notably strong, heavy bill, used for capturing large insects and handling a wide range of fruit sizes. The bill of *Chlorothraupis* is the stoutest and most robust of the group and shows a clear indication of a notch on the cutting edge of the upper mandible, a discredited taxonomic character once used to define the family. *Chlorothraupis* species, with their strong bills, also feed on insects of a wide range of sizes and even take anoles and other small vertebrates.

The Thraupidae have conservative wing shapes and lengths, most falling close the norm in wing shape and in length of primary extension for nine-primaried oscines. Their wing shapes generally reflect their sedentary status and lack of aerial foraging. Nonetheless, most species are good fliers, and some have large territories that include substantial open spaces, requiring an ability to fly rapidly between distant foraging sites and resting or nesting sites. The Fawn-breasted Tanager (*Pipraeidea melanonota*) is the only true tanager having a long primary extension, and it also is one of a small number that are partly migratory. The Hooded Mountain-tanager and a few other high-elevation tanagers of the Andes occasionally execute short aerial excursions accompanied by intense bursts of song. These flights, usually on a circular flightpath, may take the bird some 20–100 m out over a mountainside forest canopy, but none of the species concerned shows any unusual morphological structure, such as a long primary extension, that could be associated with this infrequently observed behaviour. Black-and-white Tanagers (*Conothraupis speculigera*) are now believed to be cross-Andean migrants, breeding on the west slope in Ecuador and north-western Peru, but spending a few months each year on the east slope and in nearby lowlands. Their migratory movements, though poorly understood, probably involve relatively short distances, and these tanagers do not have an unusually long primary extension.

There is a striking lack of modification also in the outer primary feathers among tanagers, including those now being reassigned to other families and the various emberizid and cardinalid genera recently shown to be genetically most closely related to thraupids (see Systematics). While wing-feather modification is commonplace in the Tyrannidae, Pipridae and Cotingidae and is usually associated with display routines, such modifications, involving narrowed or shortened or recurved outer primaries, or abnormally thickened inner secondaries, are seldom seen in oscine passerines and are almost non-existent in tanagers.

Fewer than half of the true thraupids exhibit strong sexual dichromatism, whereby the males are brightly coloured or boldly

The eleven species of Piranga *are sexually dichromatic, with males brightly coloured and typically having red in their plumage, while the females and immature birds have mainly brown, yellow or olive plumage. The immature male* ***Summer Tanager*** *at first resembles the female but its head and shoulders may be mottled with red. The amount of red in the plumage steadily increases, although males up to three years old may still have some greenish patches. The immature female often has a dull, orangish wash on her belly. The Summer Tanager does not change its plumage seasonally, unlike another migratory species which breeds in North America, the Western Tanager* (P. ludoviciana), *which has a duller non-breeding plumage. One* Piranga *species, the Red-hooded Tanager* (P. rubriceps), *is less strongly sexually dimorphic, the female having much brighter plumage than in other* Piranga *species, though still duller than the male. Molecular studies have convincingly indicated that members of the genus are not thraupids and more properly belong among the cardinals. The distribution of the* Piranga *species is centred in Mexico and Central America. Four species, the Summer, Western and Scarlet Tanagers* (P. olivacea) *and the Northern Hepatic-tanager* (P. hepatica), *occur in North America north of Mexico.*

[*Piranga rubra rubra*, Galveston County, Texas, USA. Photos: Brian E. Small]

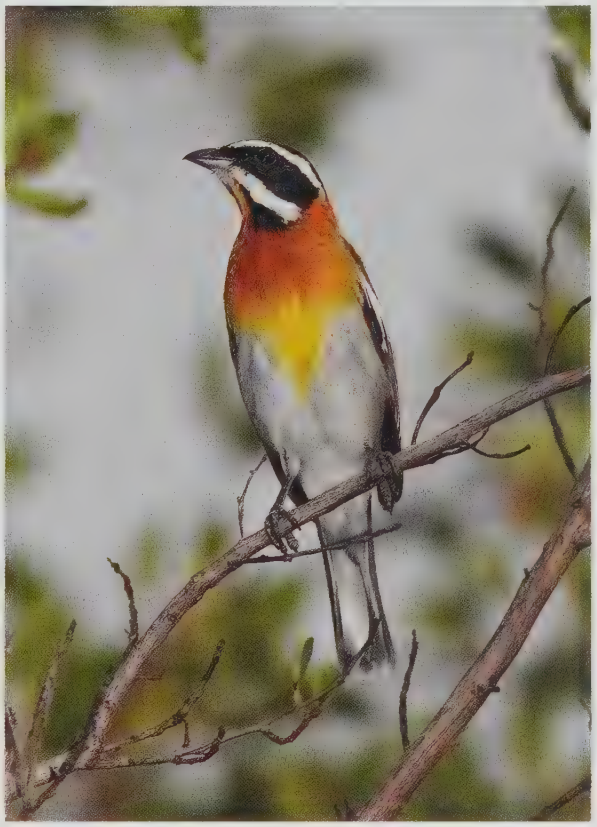
marked and the females show plainer combinations of olive, brown or buff to buffy yellow with paler underparts. Genera in which all, or almost all, of the species are strongly dichromatic include *Conothraupis*, *Creurgops*, *Thlypopsis*, *Tachyphonus*, *Lanio*, *Ramphocelus*, *Dacnis*, *Cyanerpes*, *Chlorophanes*, *Heterospingus*, *Hemithraupis*, *Chrysothlypis*, *Conirostrum*, *Xenodacnis* and some *Diglossa*. Less pronounced sexual dichromatism occurs in *Compsothraupis*, *Sericossypha*, *Nemosia*, *Trichothraupis*, *Pipraeidea* and *Chlorochrysa*, and in one species of *Bangsia*. In the largest group of tanagers, the genus *Tangara*, the sexes of a majority of the species are essentially identical, although males are usually slightly brighter. In about 20% of *Tangara*, the females differ to varying degrees, sometimes substantially, from their mates. Included in this group are the Burnished-buff, Lesser Antillean, Chestnut-backed (*Tangara preciosa*), Black-backed (*Tangara peruviana*), Green-capped, Black-capped, Sira (*Tangara phillipsi*), Silver-backed, Straw-backed and Black-headed Tanagers (*Tangara cyanoptera*), most of which are more closely related to one another than to other tanagers, and occur in dry or semi-open or lightly wooded terrain. Minor plumage differences between the sexes can be found in a few other species, including the Green-and-gold Tanager and the Emerald Tanager.

Most tanagers have a juvenile plumage that differs from that of the adult. In many, if not most, cases, this plumage resembles that of an adult but is decidedly duller and often much plainer, and initially may be almost devoid of any pattern or colour other than dull greys, browns and buffs. It is worth noting, too, that plumage sequences of tanagers have not been studied in detail. Plumage sequences are perhaps better known for the northern, migratory species of *Piranga*, a genus now thought to be better placed in Cardinalidae (see Systematics), than for any true tanagers. So far as is known, no true tanagers begin to breed when still in juvenile plumage, although young in a juvenile or subadult plumage frequently act as helpers at the nests of their parents (see Breeding). Some male euphonias, now genetically aligned with the Fringillidae (see Systematics), may breed in a subadult plumage that resembles that of the female, but differs from the latter in having a small black face mask. The pervasiveness of breeding by subadult male euphonias remains unknown, as does their breeding success rate compared with that of their adult counterparts.

While many true tanagers have bright plumage colours and bold patterns, they are, as a group, rather homogenous with regard to their bare-part colours. Any analysis of bare-part colours is largely limited to the range of colours recorded on specimen labels, to an examination of such colours visible in photographs, and to notes recorded by field observers. Each of these techniques is fraught, to some extent, with uncontrollable variation in light, interpretation of colour and, in the case of specimens, rapid post-mortem colour change. With these limitations in mind, a few generalizations are possible. Bare, coloured eyerings or other patches of coloured bare skin are not present in any species of tanager traditionally included in the family. The iris colour of most tanagers is dark, varying from brown to reddish-brown, but in a few genera, notably *Dacnis* and *Diglossa*, about half of the species have red or yellow irides and all of these are small-bodied species that feed partly on nectar and occur primarily in the canopy or middle levels of forest and wooded areas. One or two species in each of the genera *Conirostrum*, *Cissopis*, *Conothraupis*, *Hemispingus*, *Nemosia*, *Pipraeidea* and *Buthraupis* also have red, yellow or white eyes, but an obvious link between the evolution of eye colour and gender or environmental or behavioural features has not been demonstrated. Both species of *Mitrospingus* have grey eyes and several species of *Chlorospingus* have white or grey or yellow eyes, although both of these genera now properly belong with the cardinalids (see Systematics).

The bill colour of most tanagers varies from light horn-grey to blackish, often with the lower mandible paler, and it is generally homogenous within a genus. In a few genera, including *Hemithraupis*, *Chlorophanes* and *Chrysothlypis*, the upper mandible is dusky grey and the lower mandible yellowish. The bill of most *Tachyphonus* is relatively slender, with the upper mandible and tip blackish and the remainder of the lower mandible contrastingly light bluish-grey. Despite the fact that numerous tanagers have colourful plumage, only two of the more than 250 species originally placed in the family sport a brightly coloured bill. Adult Red-billed Pied Tanagers (*Lamprospiza melanoleuca*), as the English name suggests, have a bright red bill, and adult Grass-green Tanagers (*Chlorornis riefferii*) have a bright orange bill. One of the most distinctive bill patterns in the family is found in members of the genus *Ramphocelus*, the males of which have a bill that is stout, the upper mandible and tip black, with the basal two-thirds of the lower mandible obviously expanded, as if swollen, and contrastingly chalky white in colour. This expanded white portion of the bill is conspicuous, even at a distance, and especially so against the velvety black or red plumage on the

Two members of Piranga, *the* ***Red-headed Tanager*** *and the White-winged Tanager* (P. leucoptera), *are about one-third smaller than the rest, and have sometimes been placed in a separate genus,* Spermagra. *But recent DNA work does not support such treatment; it found that these two species form a clade with one of the largest in the genus, the Red-hooded Tanager* (P. rubriceps). *These three species all occur at higher elevations and are resident, rather than migratory. The Red-headed and White-winged Tanagers, and also the Rose-throated Tanager* (P. roseogularis), *have shorter and less pointed wings than other* Piranga *species.*



[*Piranga erythrocephala candida*,
Mazatlan Highway,
Mexico.
Photo: Pete Morris]

head of most species. On females of *Ramphocelus* the bill is thick but more normal in shape, and the lower mandible is pale grey, rather than chalky white.

Only a few species in this family of rainbow plumages also have brightly coloured tarsi. These include the Grass-green Tanager, with orange-red legs closely matching its bill colour and in striking contrast to the deep green plumage and chestnut mask, and the Hooded Tanager (*Nemosia pileata*), the male of which has notably bright yellow legs. In the honeycreeper genus *Cyanerpes*, males and, to a lesser extent, females have bright, almost candy-coloured red or yellow legs, or, in the case of the Short-billed Honeycreeper (*Cyanerpes nitidus*), pinkish-red legs. Both sexes of the Blue Dacnis (*Dacnis cayana*) and the Bicolored Conebill (*Conirostrum bicolor*) have pinkish legs. Bright tarsal colour is concentrated mainly in three related genera, *Cyanerpes*, allied *Dacnis* and *Conirostrum*, and may offer an additional clue to ancestral lineages. The tarsi and toes of most other tanagers are generally grey or horn or blackish, a few species having the tarsus paler or tinged yellowish or greenish-grey.

It is difficult to make generalizations about sexual dimorphism in tanager plumages. Some genera exhibit marked sexual differences in plumage, whereas in others dimorphism is slight or absent, or, as in the case of *Tangara*, obvious dimorphism is confined to only a few species. In general, smaller species, especially insectivores of lowland and lower montane elevations, are more likely to show marked sexual dimorphism in plumage than are species of larger body size and higher elevations, although there are exceptions. There has been no rigorous examination of these patterns.

Distinct juvenile plumages are worn by many, perhaps most, tanagers, but the sequences of plumages have not been worked out in a systematic manner. Even basic designations regarding age-classes are poorly known, and plumages labelled "juvenile" and "immature" should be regarded, in part, as conveniences for the purpose of discussion. In many, if not the majority of, tanager species, regardless of whether the adults are sexually dimorphic, or are bright or dull in colour, the young fledge in a modest-looking plumage. Among sexually dimorphic species, young are likely to resemble females for up to a year, as with *Ramphocelus*, or possibly longer, before acquiring an adult breeding plumage. Males of *Tachyphonus* and *Lanio* species undergo a post-juvenile moult resulting in a plumage that is mixed black and brown, and looks like neither the adult nor the juvenile. In the case of male Yellow-backed Tanagers (*Hemithraupis flavicollis*), a second annual moult is apparently required in order to achieve breeding plumage. Young of species which are not sexually dimorphic also are likely to begin life in a dull, inconspicuous plumage that is quite unlike that of the adults, although in most cases it is not known for how long these plumages are retained. The sexes of most adult *Tangara* tanagers are essentially identical, or females are slightly duller in plumage than males, but the juveniles leave the nest in a notably dingy greenish to greyish-brown plumage quite unlike that of their gaudy, multicoloured parents, and one that is confusing to field observers. Typically, when juvenile

In 2000, the Stripe-headed Tanager, with eight recognized subspecies, was split into three monotypic species, the Jamaican (Spindalis nigricephala), *Hispaniolan* (S. dominicensis) *and Puerto Rican Spindalis* (S. portoricensis), *and a fourth polytypic species, the* ***Western Spindalis****. As well as being geographically separated, the four newly recognized* Spindalis *species differ in morphology, plumage and vocalizations. The genus is confined to the Greater Antilles, except for the race* benedicti *of the Western Spindalis, which is part of the "West Indian" component of the fauna of Cozumel Island, off the Yucatán Peninsula.*

[*Spindalis zena pretrei*, Cayo Coco, Cuba. Photo: Claude Nadeau]

Like Piranga *and* Chlorothraupis, *the genus* Habia *appears to be genetically closer to the cardinalids than to the tanagers. The* ***Red-crowned Ant-tanager*** *is more closely related to* Chlorothraupis *than are other* Habia *species. Some* Habia *ant-tanagers, such as the Red-crowned Ant-tanager, are markedly sexually dichromatic: the males are mostly red and the females dull yellow, brown and olive. In other species, such as the Black-cheeked Ant-tanager* (H. atrimaxillaris), *females do not differ greatly from males but are duller. Ant-tanagers have a flat crest, which can be erected.*

[*Habia rubica vinacea*, Panama. Photo: Mike Danzenbaker/ AGAMI]

The Chlorothraupis *species are relatively large and robust, with a strong, heavy bill, and uniform, rather dingy green or olive plumage, with few distinctive field marks. Along with* Piranga *and* Habia, *they appear to belong with the cardinalids rather than the tanagers. All four are found in the undergrowth and lower storeys of very humid lowland and pre-montane forest. The* ***Ochre-breasted Tanager*** *is confined mostly to a narrow elevational band along the western base of the Andes, closely corresponding to a belt with the highest rainfall in the Western Hemisphere.*

[*Chlorothraupis stolzmanni dugandi*, Río Canandé Reserve, Esmeraldas, Ecuador. Photo: Doug Wechsler/ VIREO]

Tangara are in this plumage, they travel and forage with their parents for up to several months and, at this stage, are best recognized by identifying the adults present with them. Similarly, immature Black-faced Tanagers (*Schistochlamys melanopis*) are olive-green, very unlike the boldly black-and-grey adults, and they retain this plumage for at least a year and possibly two years. Immature White-banded Tanagers (*Neothraupis fasciata*), Blue-and-yellow Tanagers and many others spend an unknown period of time, running to months or possibly years, in a plumage that differs markedly from those of the adults.

One of the most unusual moult patterns, involving a post-breeding, or "eclipse", plumage, is exhibited by the male Red-legged Honeycreeper (*Cyanerpes cyaneus*). Adult males of this species are brilliant blue, with an azure cap and black wings and tail, while females are olive-green above and paler below. In a series of moults, young males gradually acquire adult plumage, but thereafter, following each breeding season, the males moult into a plumage similar to that of the female, but retain the black wings and tail. This moult sequence is rare among tropical species, and corresponds more closely to that of some temperate-latitude breeding birds such as northern waterfowl and migratory northern parulid warblers. First reported by A. F. Skutch in Costa Rica, this green postnuptial plumage of the male Red-legged Honeycreeper is acquired by a complete feather moult. Later, H. Sick, in Brazil, reported that this honeycreeper's striking colour change back to the blue plumage of the breeding season was due not to another moult, but to feather abrasion. Each tricoloured body feather has an olive-green tip, a blue centre and a black base; as the green feather tips abrade, the blue centre of the feather begins to show, revealing the new breeding plumage. The sequence of moults, eclipse plumages, and the possibility of feather wear in the genus *Cyanerpes* seems worthy of further investigation.

The most ambitious collection of weights and measures of the tanagers yet published is that by M. L. Isler and P. R. Isler in their monograph on the family, but these authors did not separate their data for males and females. For many less common species, and even some commoner ones, few weights, segregated by sex, are available.

The following data, taken by S. L. Hilty from live birds and specimens from the western Andes of Colombia, mainly along the River Anchicayá, in the department of Valle, are some of the very few weight data separated according to sex. This sample indicates that sexual dimorphism in size is minimal among tanagers, the males being on average similar to or very slightly heavier than the females. For seven species of *Tangara*, the details were as follows: for the Silver-throated Tanager, 13 males averaged 20 g in weight and five females 19·6 g; the average for six males of the Emerald Tanager was 15·9 g and for three females 16·3 g; of 23 individuals of the Rufous-throated Tanager (*Tangara rufigula*), 14 males averaged 20·5 g and nine females 19·8 g; seven male Bay-headed Tanagers had an average weight of 21·7 g and three females 21·6 g; five male Golden Tanagers

Molecular-genetic data indicate that the two Mitrospingus *species may be unrelated to any other Thraupidae genus. But, although they may be closest to Cardinalidae, no closely related family or sister-taxon has yet been identified and their true affinities are uncertain. Apart from the differing colours of their backs, the* ***Dusky-faced Tanager*** *and the Olive-backed Tanager* (M. oleagineus) *are very similar in appearance, but differ in vocalizations and behaviour. The song of the Dusky-faced Tanager is emphatic, but that of its congener weak and easily overlooked. Dusky-faced Tanagers are noisy, excitable and active when foraging, while Olive-backed Tanagers are quiet and sluggish.*

[*Mitrospingus cassinii costaricensis*, Costa Rica. Photo: Julian Hough]

had a mean weight of 19·9, the figure for six females being 20·7 g; the mean weight of four male Grey-and-gold Tanagers (*Tangara palmeri*) was 34·6 g, and that for four females was 30·2 g; finally, four male Blue-necked Tanagers had an average weight of 16·7 g, while the mean for three females was 17·5 g. Data for other thraupids include weights of 17 Scarlet-and-white Tanagers, of which the eleven males had a mean weight of 6·5 g and the six females 5·9 g; and, for the Lemon-rumped Tanager, four males weighed an average of 39·1 g and three females 35 g. Details are available for several additional species now generally not regarded as being true tanagers (see Systematics). These are the Orange-bellied Euphonia (*Euphonia xanthogaster*), 19 males of which averaged 13·6 g and 18 females 13·1 g; the Yellow-throated Bush-tanager (*Chlorospingus flavigularis*), seven males of which averaged 74·6 g and three females 69·5 g; and the Ochre-breasted Tanager (*Chlorothraupis stolzmanni*), twelve males of which had a mean weight of 42·6 g and seven females an average of 39·5 g.

The two Phaenicophilus *palm-tanagers form a superspecies, the Grey-crowned Palm-tanager* (P. poliocephalus) *replacing the* ***Black-crowned Palm-tanager*** *in the southern peninsula of Haiti and the immediately adjacent south-western Dominican Republic. There is a narrow zone where the two hybridize. The immature Black-crowned Palm-tanager has a grey crown. This, together with the smaller body size of the Grey-crowned species and its greater tendency to form groups, has led to the suggestion that it is a paedomorphic derivation of the Black-crowned Palm-tanager.*

[*Phaenicophilus palmarum*, Sierra de Bahoruco National Park, Dominican Republic. Photo: Doug Wechsler/ VIREO]

Habitat

As may be expected for any family as large and diverse as Thraupidae, its members are found in a wide range of terrestrial habitats. The majority of tanagers inhabit humid forest or lightly wooded areas, a few species occurring in drier, open grassy areas with scattered bushes and small trees. There are, however, a few terrestrial habitats in which the family, as presently constituted, is absent or not well represented, these including desert and semi-desert scrub, open savanna, southern beech (*Nothofagus*) forest and rocky tundra-like *páramo* and *puna* grasslands above the tree-line. Recent molecular-genetic studies, however, are revising even this long-standing view. Numerous emberizid genera, among them *Phrygilus*, *Catamenia*, *Diuca*, *Haplospiza*, *Poospiza* and *Sicalis*, appear to be more closely affiliated with the thraupids (see Systematics), and their inclusion within the tanager assemblage would indicate that many groups have successfully radiated into open and semi-open lowland and highland habitats. These include dry to arid scrub, dry and humid semi-open and open high-elevation tree-line zones, open high-elevation habitats such as *páramo* and *puna*, and in Patagonia grassland and shrub-desert. Other emberizid and cardinalid genera now believed to be much more closely allied to tanagers include *Embernagra*, *Volatinia*, *Sporophila*, *Oryzoborus*, *Saltatricula*, *Coryphospingus*, *Tiaris* and *Paroaria*, and these groups are found predominantly in lowland savanna, marshes, humid to dry scrubby areas, wooded borders and desert scrub, habitats where tanagers would otherwise have been scarce or absent. Still other groups, among them the Galapagos finches and a cluster of Caribbean genera including *Euneornis*, *Loxigilla*, *Loxipasser*, *Melanospiza* and *Melopyrrha*, have similarly been shown to be probably closest to thraupids in ancestral affinities; these are found in a variety of dry to humid

Genetic and morphological data support the continued inclusion of the ***Rosy Thrush-tanager*** *in Thraupidae. It is sometimes thought to be closer to the mockingbirds and thrashers (Mimidae), but it has also been suggested that the resemblances are convergent adaptations to a similar habitat niche. The five races occur in a series of small, isolated populations from western Mexico south to northern Venezuela. The races vary in coloration in a "leap-frog" pattern, with grey-backed populations in Mexico and South America, and an intervening black-backed population (race* eximia, *shown here) in lower Central America.*

[*Rhodinocichla rosea eximia*, El Valle, Coclé, Panama. Photo: Doug Wechsler/ VIREO]

Except when they are breeding, some tanagers are found in wide-ranging flocks of their own species. The excitable and noisy ***Paradise Tanager*** *(above) is very gregarious and often found in a single-species group of 3–15 individuals or more. But it also associates with mixed flocks of species that feed in the canopy. While many tanagers that join mixed flocks do so as pairs or small family groups, the Paradise Tanager is found in much larger groups and may make up 30–50% of the flock. Paradise Tanagers regularly associate with Green-and-gold Tanagers* (Tangara schrankii). *The two species may forage together, either accompanying mixed flocks or travelling independently of them. They move in and out of slower-moving mixed flocks, sometimes remaining for only a few minutes before flying off. In contrast, the* ***Swallow Tanager*** *(below) is almost always found in single-species groups, and is only infrequently and loosely associated with mixed-species flocks or feeding associations around fruiting trees. Individual Swallow Tanagers or groups perch well up in trees or on high exposed treetop perches, in a distinctive upright posture, often for extended periods of time. A detailed study in the 1950s in Venezuela found that, except while breeding, they spent about half the daylight hours inactive, two hours in foraging and three to four hours in social activity. While breeding, they gathered late in the afternoon on the tops of casuarina trees to catch insects for their young. This was a strongly social activity, the birds remaining in a flock even when moving to other treetops.*

island habitats, as well as in harsh arid conditions in the Galapagos Islands, zones where tanagers of previous classifications would have been scarce or completely absent.

On the other hand, several genera long regarded as tanagers, including *Euphonia*, *Chlorophonia*, *Piranga*, *Mitrospingus*, *Chlorospingus* and *Habia*, are now poised to be transferred, or have already been transferred, to other families. The moving of these groups out of Thraupidae, however, does not affect general remarks about habitat preferences of species within the family. The rest of this section is based on the family as traditionally constituted, but it also contains comments on departing species as well as on potential future incomers in the wave of taxonomic change currently affecting the family. Readers should be aware that forthcoming taxonomic revisions will almost certainly alter some aspects of the following discussion.

Tanagers are widespread across South America, from the lowlands to the tree-line. The highest diversity occurs in the Andes, but only one species, the Giant Conebill (*Oreomanes fraseri*), is regularly found above the tree-line and it inhabits a unique *Polylepis* woodland that grows at elevations higher than the normal timber-line. A few species, most notably the Blue-and-yellow Tanager, range southwards into dry regions of northern and central Argentina, and an even smaller subset occurs in dry, shrubby habitats of extreme northern Chile, but none reaches the southern beech forests of southern Argentina and Chile. In the Amazonian region, the number of species of tanager co-existing at single sites is generally lower than in the Andes, and the same is true in Central America, although almost 30 species can be found regularly in the former Canal Zone area of Panama. The number of species in the family generally declines northwards into Mexico. Four species of *Piranga*, namely the Summer, Scarlet and Western Tanagers and the Northern Hepatic-tanager, occur in North America north of Mexico, as does the vagrant Western Spindalis (*Spindalis zena*), but all four of the species are now believed to be much closer to cardinalids than to thraupids; this is probably also true of the spindalis, leaving the White-collared Seedeater (*Sporophila torqueola*), presently in Emberizidae but almost certainly a thraupid, as the only resident breeding species of tanager north of Mexico. A few other current emberizid species about to be reclassified as tanagers, including two species of *Tiaris* grassquit, and the Bananaquit, already transferred to Thraupidae, occur as accidentals in southern Florida, but none breeds there.

Tanagers are generally most diverse in regions of humid and wet forest and forest borders, occurring in reduced numbers in dry and semi-open regions. Several species have readily adopted human-altered environments, especially in urban areas, parks, gardens, farms and ranchland, so long as there are trees and shrubs. Tanagers, whether considered in the traditional sense or in light of the many probable new taxonomic revisions, are an important avian component of almost all wooded habitats across Middle and South America. They presently comprise about 7–9% of the total avian diversity in the Amazonian lowlands. This figure increases slightly in the foothills, peaking at about 10–16% of the species diversity in cool middle-Andean elevations between about 900 m and 1800 m; thereafter, their representation levels off or declines slightly with increasing altitude up to the tree-line. Several genera, including *Hemispingus*, *Buthraupis*, *Anisognathus*, *Iridosornis*, *Diglossa*, *Conirostrum* and a few monotypic genera, are well represented at high elevations up to the tree-line, but their distributions all end at the upper limit of tree growth. Thraupid representation also declines in dry rainshadow valleys of the Andes and in dry, semi-open lowland habitats: tanagers accounted for no more than 5·7% of the avian diversity in a dry intermontane valley near Tambo, in Bolivia, for barely 4% in a dry-forest coastal site near Tucacas, in Venezuela, and for less than 3% in ranchland in Apure, also in Venezuela. In dry and progressively more open habitats in Argentina and Chile their representation also declines southwards, eventually only one or two species persisting as seasonal breeders or visitors. The pattern is similar in Central America, with areas of humid forest supporting the greatest number of species, dry forest harbouring fewer species, and overall diversity declining as one moves northwards.

Recent genetic findings (see Systematics) will significantly change the complexion of the family. It also will change many of the figures mentioned above. While a definitive thraupid taxonomy is not yet a reality, it is close to becoming one, and it is possible to glimpse what lies ahead. What seems sure to emerge is a family still dominant in Andean cloudforests and in Amazonia, although with the loss of a few well-known genera, including *Euphonia*, *Chlorophonia*, *Chlorospingus*, *Mitrospingus*, *Chlorothraupis* and *Habia*, and perhaps others; a family also much better represented in semi-open regions in the Neotropical lowlands, above the tree-line in the Andes, across

In common with most small passerines, the ***Chestnut-bellied Euphonia*** *performs stereotyped wing-flicking and tail-flicking movements when about to fly, as these birds are doing. The Rufous-bellied Euphonia* (Euphonia rufiventris)*, which forms a superspecies with the Chestnut-bellied Euphonia and is very similar in behaviour, often also flicks its tail to one side while foraging. Like many other euphonias, the Chestnut-bellied Euphonia is usually seen singly or in pairs, and sometimes in small groups. The Rufous-bellied Euphonia is even less frequently seen other than in pairs or singly, though both of these euphonias are regular members of mixed-species flocks.*

[*Euphonia pectoralis*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

*Long-billed birds such as this **Purple Honeycreeper** can have practical difficulties in reaching their neck and upper breast and back while preening. In general, longer-billed species spend more of their grooming time in scratching with their feet than do shorter-billed congeners. The Trinidadian race, shown here, has a significantly longer bill than the nominate. Purple Honeycreepers are restless and nervous birds, constantly fidgeting and wing-flicking, often barely pausing to rearrange a few feathers as they go.*

[*Cyanerpes caeruleus longirostris*, Trinidad. Photo: George M. Jett]

the entire cone of southern South America, and in the Caribbean and the Galapagos Islands. Genetic evidence is pointing to a thraupid radiation that has been successful in colonizing not only core tropical forested habitats, but also a variety of marginal, semi-open and island habitats. Ancestral lines have radiated into colder, semi-open Andean highlands above the timber-line, as inhabited by, for example, *Phrygilus*, *Poospiza*, *Catamenia* and *Sicalis*, into semi-open habitats in humid lowlands, such as those occupied by, for instance, *Sporophila*, *Oryzoborus* and *Volatinia*, and a variety of marginal, dry and arid scrub and semi-open habitats, including those colonized by *Diuca*, *Embernagra*, *Saltatricula*, *Coryphospingus* and *Rhodospingus* on the South American mainland, with a number of genera that have been equally successful in colonizing marginal habitats in the Caribbean and Galapagos. If current preliminary findings continue to be validated, one of the more surprising changes to traditional taxonomies will be that a significant proportion of all the passerines in the Galapagos may trace their ancestral lines to a tanager radiation, rather than an emberizid one. Curiously, for all the likely success of thraupid lineages in colonizing marginal high-Andean habitats and the farthest reaches of Patagonia, the presence of any tanager, even as a seasonal visitor, in North America north of Mexico now seems remote. However, there is a small population of the probably thraupid White-collared Seedeater (see Systematics) in southern Texas.

Tanagers are amongst the groups of birds most closely associated with Andean cloudforests, at least in popular image. In these cool, perpetually misty and moss-draped forests regularly some 25 to 46 species occur syntopically in an ever-changing species mosaic from Venezuela south to Bolivia, and these figures will not change greatly even with the dramatic taxonomic reorganization occurring within the family. In the Andes, two areas are paramount for tanager diversity: the western slope of the western Andes in Colombia and north-western Ecuador, and the eastern slope of the Andes from Colombia south to Bolivia. It is in these broad areas that the family reaches its greatest diversity, and a significant part of this extraordinary diversity is the result of radiation within a single genus, *Tangara*.

The number of syntopic species of tanager in the Andes of southern Venezuela, the coastal mountains of south-eastern Brazil and the humid lowland forests of Amazonia is only slightly smaller than that in the Andes from Colombia southwards. For example, 35 species of tanager have been recorded at the Explornapo Lodge near the River Napo, in north-eastern Peru, while a 1-km² site at Cocha Cashu, in the Manu Biosphere Reserve of southern Peru, contained 40. In west-central Brazil, 35 species have been recorded at Alta Floresta, in Mato Grosso. Away from humid and wet forests in Amazonia and the Andes, the diversity at single sites falls. In the Guianan lowlands from eastern Venezuela eastwards to French Guiana, the number of tanagers at single sites declines to about 15–30. A similar decline occurs in Venezuela north of the Orinoco and in dry northern coastal regions of Colombia. The average single-site diversity of tanagers in Panama and Costa Rica is about 15–20 species, similar to that in the Guianas, and northwards through Central America the decline continues, and this pattern is unlikely to change much with taxonomic revisions. The entire country of Mexico holds barely 30 species of tanager, and most of these are found in the humid south-eastern lowlands. A similar decline occurs from Amazonian Brazil southwards into Argentina. The humid Atlantic Forests of south-eastern Brazil and adjacent eastern Paraguay and north-east Argentina, however, harbour many tanagers and several endemic genera, such as *Compsothraupis*, *Orchesticus*, *Orthogonys*, *Pyrrhocoma* and *Stephanophorus*. In highland Atlantic Forest, as in the Andes, it is the diversity of *Tangara* that is most striking, with up to five species found together at some sites. Single-site totals for the family also are high, on average about 25–30 species, although generally lower than at Andean sites.

Most broadly defined habitats are, on close inspection, composed of a number of micro-habitats utilized to varying degrees by birds. The Amazon Basin, for example, does not comprise a single sweeping rainforest habitat from end to end, but a complex mosaic of habitats and micro-habitats encompassed within a broadly defined region. It also is affected by rather dramatic regional differences in annual rainfall, and the distribution of this rainfall through the year. Tanagers occur virtually throughout this matrix of habitats, some using many habitats, while others are more narrowly constrained. Few, however, appear to be as specialized in habitat preference as are many suboscine taxa. Habitats within the Amazon Basin, in the broadest terms, consist of *terra firme* forest, floodplain forest known as *várzea*, swamp-forest known as *igapó*, several types of white-sand forest and scrub, river edges, river islands and their associated successional vegetation stages, oxbow lakes, treefall light-gaps, palm forests, morichales (stands of vegetation dominated by the moriche palm, *Mauritia flexuosa*), vine forests, sites with a high density of fig

Preening is a bird's main defence against ectoparasites such as lice. Foraging habits can influence the load of parasites that a species carries. The ***Scarlet-and-white Tanager****, which feeds in the outer foliage of trees and shrubs, is likely to have a lower level of infestation than a bird that gleans arthropods from the bark. Studies in the Brazilian Atlantic Forest have also found that ectoparasites tend to be more prevalent on birds that join mixed flocks regularly than on those that do so only occasionally.*

[*Erythrothlypis salmoni*, El Danubio, Buenaventura, Valle del Cauca, Colombia. Photo: Roland Seitre]

trees (*Ficus*), the last mainly in floodplains, and bamboo patches, black-water rivers and white-water rivers, among others. Any one or all of these habitats can vary separately or in concert with regard to seasonal distribution and quantity of rainfall and in micro-climate factors that affect everything from the extent of epiphytic growth in the canopy to openness of the understorey. Some forest types differ dramatically from immediately adjacent ones, while others differ in less obvious ways from nearby vegetation types. The underlying soils also strongly influence the type of vegetation that is present, and scientists are only beginning to comprehend this influence on overall diversity. The diversity of forest types and associated micro-habitats is an important contributor to overall species diversity within the Amazon Basin. These factors, together with the sheer size of Amazonia, the important historical climatic changes and numerous immense rivers acting as isolating mechanisms, have contributed to the raising of the species diversity in Amazonia above that which is supported in the Guianan lowlands and lower Central America. The large number of habitats found within relatively small areas provide more opportunities for habitat and resource specialization, and

Comfort behaviour such as sun-bathing may help to control ectoparasites, either killing them directly or exposing them to preening as they try to escape from the heat. It may also kill feather-degrading bacteria. A number of tanager species, including the ***Green Honeycreeper*** *have also been observed anting, which possibly involves the use of formic acid produced by the ants (Formicidae) to control parasites, although it has been suggested that it also stimulates the skin and gives the birds pleasure. Green Honeycreepers "ant" in trees, rather than on the ground.*

[*Chlorophanes spiza spiza*, Trinidad. Photo: Greg & Yvonne Dean/ WorldWildlifeImages.com]

*This **Brazilian Tanager** is scratching its head by the indirect method, bringing its foot up over its wing. This is probably typical of thraupids as a whole; in a related family, the Cardinalidae, so far as it is known, all species use the indirect method. Like scratching, the roosting habits of tanagers have received little attention. However, tanagers that roost in pairs seem to be always slightly separated from each other; and Palm Tanagers* (Thraupis palmarum)*, which roost as pairs within groups of 10–75 birds, also seem to maintain a distance, probably because otherwise ectoparasites could pass between them.*

hence for greater numbers of species to co-exist without directly competing, than would be possible in less complex environments. Some avian families, such as the ovenbirds, the thamnophilid antbirds and the tyrant-flycatchers, have been particularly successful in exploiting this variety of habitats.

Tanagers are found in most, if not almost all, terrestrial habitats in the tropical lowlands, but until the taxonomy of the family is more clearly understood the full spectrum of habitat utilization within the family cannot be properly analysed. Nevertheless, a few patterns do emerge among genera believed to be true tanagers. Species of *Ramphocelus* tanager, for example, occur mostly in shrubby forest borders, disturbed areas and second growth of various ages, one of them, the Masked Crimson Tanager (*Ramphocelus nigrogularis*), usually inhabiting shrubby borders along watercourses and swampy areas. Shrike-tanagers, along with several species of *Tachyphonus* and the Yellow-backed Tanager, follow mixed-species foraging flocks in the subcanopy of humid forest; dacnises, honeycreepers and *Tangara* species form their own flocks in canopy and emergent forest trees and, from time to time, also join more diverse mixed flocks. Red-billed Pied Tanagers forage mainly in emergent trees in tall primary forest, whereas Guira Tanagers (*Hemithraupis guira*) and Hooded Tanagers forage in a variety of secondary and thinned woodland habitats and in semi-open areas with scattered trees. *Thraupis* tanagers occur in disturbed areas, river edges, parks, gardens and semi-open areas in dry to humid regions, and also wander across the tops of canopy trees in tall lowland forest. The genera *Schistochlamys*, *Neothraupis* and *Cypsnagra* occur in a variety of semi-open grasslands with scattered bushes and small trees in the lowlands. Although *Sporophila* seedeaters, *Sicalis* yellow-finches and some other genera have not previously been recognized as tanagers, recent molecular evidence suggests that they are best treated as thraupids, rather than as emberizids (see Systematics). Several of these genera are found in marshes and open grassland, thus indicating that, within lowland tropical latitudes, tanagers have spread into virtually all major habitats.

Similar habitat-partitioning is evident in highland habitats in the Andes. One highland species, the Blue-capped Tanager, occurs in second growth and disturbed areas, while all except one member of the genus *Thlypopsis* are found in scattered shrubby vegetation in high and often dry valleys. Several other Andean genera are closely associated with humid pre-montane or higher-elevation montane forest and borders, where they forage mostly above the understorey. This group includes the genera *Creurgops*, *Cnemoscopus*, *Calochaetes*, *Bangsia*, *Buthraupis*, *Anisognathus*, *Chlorornis*, *Dubusia*, *Delothraupis* and *Iridosornis* and many *Tangara* species. Other predominantly Andean genera are more closely associated with dense undergrowth and bamboo in pre-montane or montane forest; they include *Hemispingus*, *Catamblyrhynchus* and the enigmatic *Urothraupis*. *Diglossa* flowerpiercers, another Andean group with an ancestral radia-

*Anecdotal evidence suggests that bathing takes place more frequently in hot lowlands than in cool montane habitats, especially late in the afternoon on hot, sunny days. The **Grey-headed Tanager** seeks out habitats where standing water is available: in Amazonia, the nominate race (shown here) occurs mainly in the undergrowth of swampy* várzea *forest and other poorly drained wooded sites, and when in drier habitats this species is usually found near watercourses.*

[*Eucometis penicillata penicillata*,
Atlantic Rainforest, Brazil.
Photo: Cassiano Zaparoli]

tion northwards into the highlands of Middle America and the tepuis of eastern Venezuela, occur mostly in humid shrubby or bushy areas, forest borders and stunted tree-line woodland. *Conirostrum*, unlike many thraupid genera, is less easily categorized. Active and warbler-like in appearance, about half of its members are confined to, or occur in, such disparate lowland habitats as mangroves, *Cecropia* trees on new Amazonian river islands, dry forest, gallery woodland and second-growth woodland in humid areas, while the remainder are found at high elevations in shrubby areas and humid forest borders in the Andes. The Cinereous Conebill (*Conirostrum cinereum*) is exceptional, as it has both a lowland population and highland populations. From south-western Ecuador south to western Chile it occurs in arid scrub at sea-level, but it ranges upwards in arid to moderately humid scrub to the tree-line or higher in the Andes, thus spanning a range of elevations and habitats far greater than any congener. In the north of its range it occurs only in wooded borders and shrubs in the highlands.

Of the genera no longer believed to belong with the true tanagers (see Systematics), most are found in humid forest or wooded borders. For example, one or more *Chlorospingus* bush-tanagers can be found in almost all humid montane forests from Mexico south to Bolivia. One or more members of the genus *Euphonia*, now thought to belong with Fringillidae, can be found in almost all dry to humid forest or lightly wooded habitats from western Mexico south to northern Argentina. *Chlorothraupis*, *Habia* and *Mitrospingus* are denizens of undergrowth and thickets in lowland and lower montane regions. More catholic in habitat choice are the large and mostly slow-moving *Piranga* species, one or more of which occur in a wide range of forests, forest borders, and semi-open and second-growth vegetation from lowland to highland areas, and locally also in dry to humid woodland. The four migratory *Piranga* in North America breed in a wide range of deciduous and evergreen forests.

Within the Amazonian lowlands, tanagers are arboreal and occur primarily in habitats associated with middle and upper strata of forest, or lower down along shrubby borders of forests, lakes and rivers. In a landmark study in the Manu Biosphere Reserve, in south-eastern Peru, in the 1970s and early 1980s, J. W. Terborgh and several investigators found that, of the 40 species of tanager recorded in 1 km² of forest and river edge at the Cocha Cashu Biological Station, only three foraged primarily in the understorey. Two of these, the Grey-headed Tanager and Red-crowned Ant-tanager, occurred inside the forest, and the third, the Orange-headed Tanager (*Thlypopsis sordida*), occurred in tall canegrass (*Gynerium*) on river sandbars outside the forest; since the ant-tanager genus *Habia* is now believed not to be closely related to tanagers, only two true thraupids occur regularly in the understorey. The remaining 37 species were associated with a variety of mostly arboreal forest habitats, or along forest borders and lake margins. Of the 15 habitats quantified in the Manu study, tanagers were present in eight (albeit only infrequently in two of these) including: river margins; cane brakes; swamp-forest; low-lying seasonally flooded transitional forest; high-ground forest; lake margins; marshes; and *Mauritia* palm swamps. Habitats not utilized by tanagers included river shores and lakeshores, lakes, bamboo, the aerial zone, and forest-stream margins. No tanagers were dependent upon or restricted to *Guadua* bamboo and only one species, the Magpie Tanager (*Cissopis leveriana*), occurred even occasionally in marshes; only the Palm Tanager (*Thraupis palmarum*) was seen in *Mauritia* palm swamps, and only the White-vented Euphonia (*Euphonia minuta*), now generally regarded as a fringillid, was regularly associated with forest openings. The transfer from Emberizidae to this family of the *Sporophila* seedeaters, which in the Manu region occur primarily in grassy lake margins, will not change these results appreciably. It is evident that tanagers have radiated into and now occupy almost all important arboreal habitats in Amazonia.

Nowhere, however, do tanagers seem to specialize in the subdividing of structural features in an environment as finely as they do in the Andes while, at the same time, making use of several broad habitat types such as wet montane forest, forest borders, and various stages of secondary growth and thinned woodland. In Andean cloudforests, six to ten species of *Tangara* may occur together at a single locality. Just as remarkable as this large number of co-existing congeners, however, is the fact that the composition and abundance of species continually change with elevation, so that a community of 6–10 species in the foothills will gradually be replaced by different species at successively higher elevations. Thus, a mixed flock containing seven or eight or nine species of *Tangara* at the base of the Andes will often share few or none of its members with a mixed flock of *Tangara* in a montane forest 1000–1500 m higher up the slope. To a lesser extent, various species or subspecies also replace each other latitudinally

Whereas birds of the undergrowth, forest edges and clearings readily use pools on the ground, highly arboreal species such as Tangara *tanagers generally bathe in tree sites such as rotted-out branch stubs, knotholes, large leaves and "tank" bromeliads. But the opportunistic* ***Bananaquit*** *is active at almost any height, from near ground level to the canopy, and will bathe with equal readiness in pools on the ground or, as here, in a century plant* (Agave americana) *leaf.*

[*Coereba flaveola uropygialis*, Willemstad, Curaçao. Photo: J. R. Riemer/ AGAMI]

Although only recently recognized as part of the tanager family, the ***Bananaquit*** *is typical of many tanager species in being a poor singer. It does sing persistently, however, producing songs that typically consist of a short, high-pitched series of unmusical buzzes, "chip" notes and insect-like hisses. Among the 41 subspecies distributed from south-eastern Mexico to Brazil, Peru and Bolivia, and across the Caribbean islands, there are hundreds of regional dialects and much individual variation within regions. The songs can be confused with those of hummingbirds (Trochilidae), conebills* (Conirostrum) *and dacnises* (Dacnis)*, and even with insect sounds.*

[*Coereba flaveola chloropyga*,
Iguazú National Park,
Argentina.

from north to south in the Andes, such that a middle-elevation flock on the east slope of the Andes in Venezuela or Colombia would not contain quite the same composition of species as a flock in humid montane forest at a similar elevation on the eastern slope in southern Peru or adjacent Bolivia. In numerous cases, the replacement of one species by an allied species occurs at large natural barriers. In the Andes, this replacement often takes place where an unusually deep mountain valley nearly splits the mountain range perpendicularly to its axis. This can be seen best at the Táchira Depression, in southern Venezuela, and the Marañon Valley, in Peru. In both cases, the valleys are so deep and low in elevation, and the habitat drier and so dramatically different in the valley bottoms compared with adjacent higher elevations, that they provide effective barriers preventing montane birds from moving from one side of the valley to the other.

While *Tangara* tanagers overlap broadly in their use of fruit resources, they search for arthropods by employing a variety of species-specific techniques and a remarkably fine-grained divi-

Along with its many beautiful but unmusical species, Thraupidae does include some fine singers, such as the ***Cinnamon Tanager****. Its song, delivered from an open perch on top of a tree or shrub, is a leisurely and exceptionally sweet series of phrases, some of which may be repeated over and over. Harsher critics have called it "rather monotonous". There is some geographical variation, but the pattern and rich melodic tone are easily recognizable. Its congener, the Black-faced Tanager* (Schistochlamys melanopis)*, also has a musical song involving repeated phrases.*

[*Schistochlamys ruficapillus capistrata*,
Serra da Canastra
National Park,
Minas Gerais, Brazil.
Photo: Edson Endrigo]

Vocal duetting is performed by several genera of tanagers and may be used in different contexts, from territorial defence to maintaining contact in dense undergrowth. Pairs of ***White-rumped Tanagers****, for example, sing to announce their territory ownership. They are conspicuous as they sit close together in the tops of isolated trees and shrubs, and sing their loud, rollicking duets. The song, heard mainly prior to sunrise, but also periodically during the day, is a rapid and loud series of melodic whistles, the phrases given over and over in rapid succession. The duet may be antiphonal or synchronized.*

[*Cypsnagra hirundinacea pallidigula*, Jalapão State Park, Mateiros, Tocantins, Brazil. Photo: Robson Silva e Silva]

sion of their foraging substrates. In western Ecuador, for example, Naoki, working at an elevation of about 1250 m, found that, in a community of seven *Tangara* tanagers, all of them used largely the same fruit resources and harvested these in the same way, but the species differed sharply in the manner in which they searched for arthropod prey and the substrates on which they searched. She found that these various species of *Tangara* foraged on bare or partly mossy branches, or mossy surfaces, or live foliage, or dead leaves, or flower buds. Moreover, the location of these structures within a tree or shrub was also important. Members of the genus regularly subdivided the parts of trees and shrubs where they habitually foraged, such that some species foraged more in the inner part of a tree or branch, others in the middle, and still others in the outer twigs and foliage. The searching techniques employed by the seven tanagers also varied from species to species and involved sallying, pulling, probing, hanging upside-down, hanging to the side, hanging downwards, reaching down, reaching to the side, reaching up, and gleaning. Some species used combinations of substrates, habitats, foraging positions and attack manoeuvres, resulting in a remarkably precise habitat subdivision in the utilization of arthropod resources. With such a rich variety of foraging manoeuvres, substrates, tree positions and habitats, it is perhaps not surprising, then, that so many similar species can co-exist.

An example of the exceedingly fine discrimination of foraging sites used by some *Tangara* is illustrated by two of the seven species studied by Naoki. The Golden Tanager consumed mostly similar fruits, and in similar proportions, to those taken by the Flame-faced Tanager, the two thus overlapping almost completely in the fruit portion of their diets. When foraging for arthropods, both species also habitually searched along branches by leaning down and peering at the sides of the branches, first on one side, and then hopping once or twice along the branch and repeating the process on the other side of the branch as they progressed outwards. Both also foraged mostly on the inner section of branches, so that the average size of the branches inspected was similar for the two species, but from two to four times larger than the branch sizes used by the other five *Tangara*. In addition, the Golden and Flame-faced Tanagers did most of their foraging in primary forest, the Flame-faced Tanagers differing mainly in including slightly more trees in semi-open areas. Up to this point, these two species were nearly identical in their foraging manoeuvres, tree position and habitat use, but, in a critical fourth dimension, the type of substrate used, they differed dramatically. Flame-faced Tanagers obtained approximately 80% of their arthropod prey from moss on the inner part of limbs, and took most of the remaining prey items from partly mossy limbs, revealing that, when foraging for arthropods, this species is a moss specialist. Golden Tanagers, on the other hand, took only about 40% of their arthropod prey from moss and a further 20% from partly mossy limbs; they captured a sizable 35% on bare limbs, a micro-habitat substrate almost completely ignored by allied Flame-faced Tanagers.

In examples where the foraging behaviour of some *Tangara* tanagers are very similar, the species may avoid direct competition by having non-overlapping distributions. The Speckled (*Tangara guttata*), Spotted, Yellow-bellied (*Tangara xanthogastra*) and Rufous-throated Tanagers all feed heavily on tiny berries of *Miconia* and other melastomes, these accounting for perhaps half or more of their food choices, and each species also searches for insects primarily on twigs and foliage near the outer ends of branches. Their distributions are largely discrete, but in areas where two or more of the species overlap, such as in southern Venezuela, the Spotted Tanager occurs in the lowlands, and the Speckled and Yellow-bellied Tanagers at higher elevations. Here in the tepui highlands, Speckled Tanagers forage primarily in terminal twigs and foliage, while Yellow-bellied Tanagers spend more time in utilizing larger-diameter, interior branch surfaces.

Many tanagers in the Amazonian region are broadly distributed geographically, whereas in the Andes distributions are more apt to be long and linear, corresponding to narrow elevational bands of suitable forest. Distributions that follow a particular forest type in the Andes often extend for hundreds and even thousands of kilometres along an eastern-slope or western-slope contour of the mountains, but may extend little more than a thousand metres vertically. A dozen or more species of tanager, however, have unusually small distributions, in some cases limited to the headwaters of a single watershed or mountain ridge. For example, the Sira Tanager is found only at the north end of a single isolated mountain top in east-central Peru, where it presumably requires the cooler montane forest confined to the top of this isolated ridge. The habitat of some other species appears not to

*The dawn song of the **Green-headed Tanager**, given from the crown of a tree, consists of a high-pitched, trisyllabic phrase, steadily repeated up to 90 times a minute. For a number of* Tangara *species, however, no song has yet been described. Some apparently sing rarely or not at all, although it is often unclear which of their vocalizations could actually comprise a song. Many songs that have been described consist of repeated buzzing, wheezing or ticking. Rare exceptions include the Grey-and-gold Tanager* (T. palmeri), *a notably vocal species with several semi-musical calls.*

[*Tangara seledon*, Brazil.

differ appreciably from that in adjacent areas, and exactly how or why the distributions of these birds are so restricted remains unknown. For example, the Orange-throated Tanager (*Wetmorethraupis sterrhopteron*) is known only from a small area of wet foothill forest in the upper Marañon Valley of northern Peru and adjacent Ecuador. The species was not discovered until the early 1960s and was considered so unusual that it was placed in a monotypic genus; it would seem, therefore, to have no closely related competitors. Furthermore, the habitat in which it occurs, with the exception of a few arid valleys, extends essentially along the length of the eastern base of the Andes from Colombia south to Bolivia. So, why is this species confined to such a small area? At the present, the factors limiting the distribution of this species so sharply are not known. Perhaps it is a relic species, historically more widespread, but now reduced to a single small area because of factors as yet unidentified. It is not readily apparent that the wet forest in this small area differs much from that in other, contiguous areas. Sadly, this rare species is now being hemmed in by deforestation, making the likelihood of learning the reasons for its small distribution ever more remote. In another example, Parodi's Hemispingus (*Hemispingus parodii*) lives in dense bamboo and wet, stunted forest at the tree-line in the department of Cuzco, in southern Peru. The species is fairly common locally, but has yet to be found farther to the north or south, despite the fact that this narrow band of wet tree-line vegetation extends more or less uninterrupted northwards to northern Peru and southwards into Bolivia. The Green-capped Tanager provides yet another example of a species confined to a single high-lying, semi-arid valley in the intermontane region of extreme southern Peru. The habitat is not unusual, because dry, intermontane valleys are characteristic of many highland areas in Peru and southwards into Bolivia. What factor or factors, modern or historical, cause this species to be confined to a single valley remain unknown.

Typically for most of the genus Diglossa, *the song of the **Grey-bellied Flowerpiercer** is a rapid, complex jumble of high-pitched notes, lasting around three seconds. The song is repeated at intervals of a few seconds during peak singing bouts, which take place at dawn, from a perch in the top of a shrub or small tree. Both sexes sing. As well as breeding territories, these flowerpiercers hold individual territories and are aggressive in defending small patches of flowers.*

[*Diglossa carbonaria*, Tunari National Park, Cochabamba, Bolivia.

Numerous tanagers are associated with cool, mossy cloud-forests, and no group exemplifies this better than the genus *Tangara*. With some 49 species, *Tangara* is the largest single genus of birds in the Western Hemisphere. It is well represented across Amazonia and in Atlantic Forests of southern Brazil and a sprinkling of species have found their way northwards into Central America and south Mexico, but the genus is nowhere else as diverse as it is in the Andes. From the Amazonian lowlands and foothills along the eastern base of the Andes, various *Tangara* species gradually replace one another in succession upwards to almost 2500 m, a single species, the Blue-and-black Tanager, ranging nearly to the tree-line. This grand panoply of avian colour unfolding up the verdant slopes of the Andes represents one of the greatest of all radiations of avian diversity. About half of the Andean *Tangara* depend heavily on wet forest, the remainder favouring a variety of more disturbed habitats, including treefalls and semi-open areas, but within these *Tangara* communities there

With the likely transferral of the genus Piranga, *perhaps to the Cardinalidae, Thraupidae will lose some of its finest songsters. The song of the* ***Flame-colored Tanager****, given from a high perch, is a long series of phrases of 3–6 notes, rich, musical and reminiscent of a vireo (Vireonidae), but with a slight burr typical of the genus. Some species sing for up to half an hour at dawn, giving their slow, rich carolling from a favourite perch. Others may be less rich in their delivery: the song of the Highland Hepatic-tanager* (P. lutea) *has been called "rather repetitious", and that of the Lowland Hepatic-tanager* (P. flava) *"melodious but with little variation".*

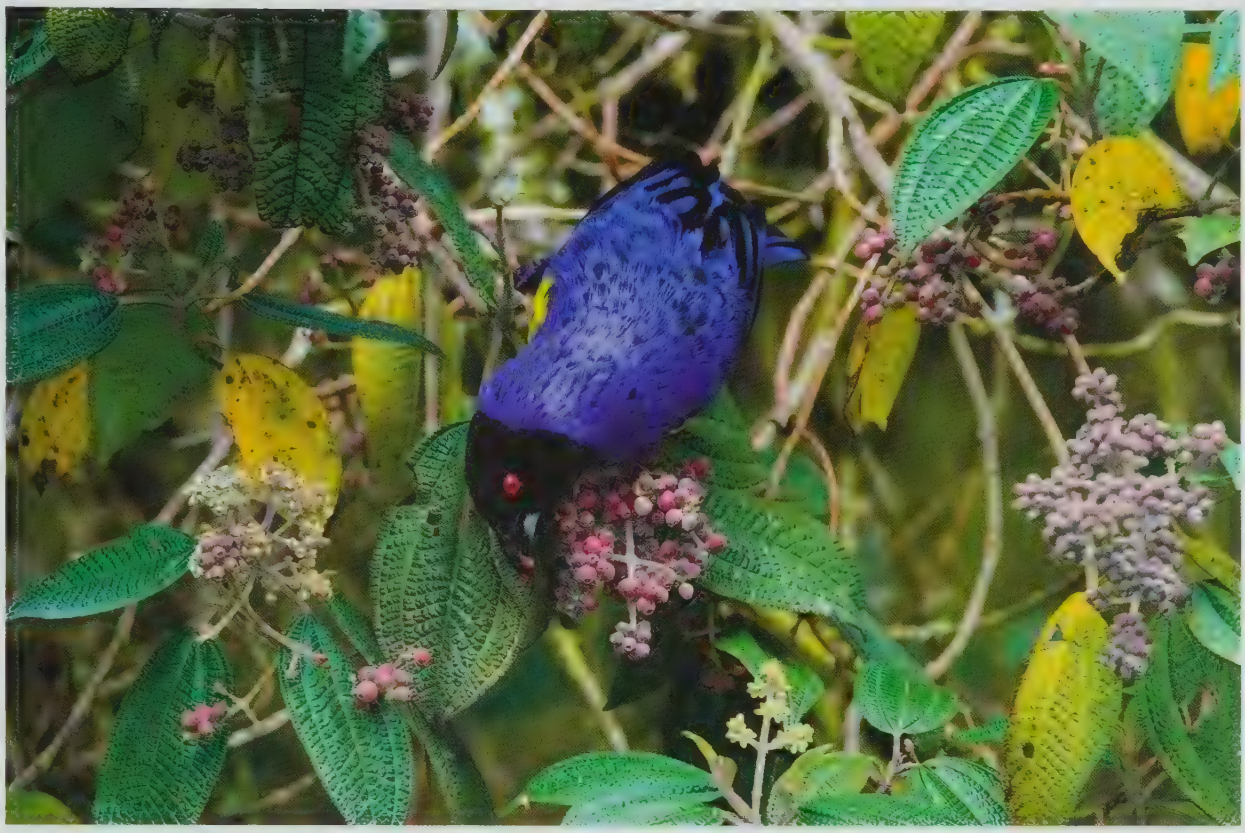
[*Piranga bidentata bidentata*, Santa Rita Mts, Madera Canyon, Arizona, USA. Photo: Rick & Nora Bowers/VIREO]

is exceptionally broad habitat overlap, almost all of them using the same spectrum of humid forest, wooded borders and light woodland at times. In a community of eight *Tangara* tanagers in the Anchicayá Valley of western Colombia, Hilty found that two species, the Blue-necked and Golden-hooded Tanager, occurred primarily in semi-open areas with scattered trees, while the remaining six species used a combination of wet and mossy forest interior, forest borders and secondary woodland. These six, however, favoured certain forest micro-habitats over others, despite broad overlap. For example, the Emerald, Silver-throated, Bay-headed and Golden Tanagers occurred more often inside tall, wet forest, the Grey-and-gold Tanager used mainly high canopy and emergent trees in the forest and in clearings, and the Rufous-throated Tanager favoured forest borders and secondary woodland and borders. Within the Amazon Basin it is also not unusual to find most *Tangara* sharing the same spectrum of forest and forest-canopy habitats, only one species, the Masked Tanager, occurring mainly in open or semi-open areas with scattered tall trees. The other species make use of the tallest emergent forest trees and the canopy and subcanopy heights, and, indeed, they are often found together in the same mixed flocks of tanagers and honeycreepers early in the morning. Later in the day, they are likely to forage together with other species in large mixed canopy flocks.

A few tanagers are associated with semi-open habitats and grasslands where there are only scattered trees and bushes and, in Brazil, with light-canopied *cerrado* woodland. Two south-central Brazilian species, the White-banded Tanager and White-rumped Tanager (*Cypsnagra hirundinacea*), are found only in savanna with a peppering of trees and shrubs. Interestingly, the White-banded Tanager bears a striking resemblance in appearance to the Great Grey Shrike (*Lanius excubitor*) and Loggerhead Shrike (*Lanius ludovicianus*) of northern temperate regions, both of which occupy partly open terrain similar to that in which this tanager is found. The more widespread Black-faced Tanager occurs in similar open to bushy habitats, as well as in the mixed grassland and scrub that develops on white-sand soils across southern Venezuela and the Guianas, and in grassland and gallery-forest mosaics that characterize the strongly seasonal *llanos* climate of central Venezuela and north-eastern Colombia. The Red-shouldered Tanager is closely associated with the tough, sclerophyllous-leaved bushes that dot grassland on Guianan white-sand soils. It is not known what factors restrict it to this specialized vegetation of white sandy soil while the more widespread Black-faced Tanager thrives in a broader range of equally open habitats. Only four species of *Tangara* occur primarily in semi-open habitats, and they overlap little in range with the others. The Burnished-buff Tanager thrives both in white-sand scrub and in strongly seasonal, mixed grassland and woodland that characterizes much of northern and central Venezuela and adjacent Colombia east of the Andes, habitats similar to those occu-

Some tanagers always forage in a particular stratum, but the ***Blue-winged Mountain-tanager*** *forages at various heights, from below eye level to high in the canopy. Blue-winged Mountain-tanagers forage conspicuously in pairs or single-species groups of up to ten individuals. They also join mixed-species flocks containing other tanagers and New World warblers (Parulidae), but frequently strike out on their own in erratic little forays. They are energetic, nimbly run-hopping along slender, mostly bare branches, and working out fairly quickly to terminal foliage clusters.*

[*Anisognathus somptuosus cyanopterus*, Bellavista Cloud Forest Reserve, Tandayapa, Ecuador. Photo: Tui de Roy/ Roving Tortoise Photos]



Communities of many species of tanager are able to co-exist because they divide available habitats and resources between them. The ***Vermilion Tanager*** *belongs to the monotypic genus* Calochaetes, *one of a number of Andean genera, also including* Tangara, *which are closely associated with humid montane forest and forest edges, where they forage mostly above the understorey. Other predominantly Andean genera found in these forests are more closely associated with dense undergrowth and bamboo. Vermilion Tanagers have a short, thick bill that is able to take larger fruits than can most tanager species, and they are not often seen at the small-berried trees used by many other species.*

pied by the Black-faced Tanager. It overlaps only very locally, for example near Ocaña, in the Colombian department of Norte de Santander, with the allied Scrub Tanager, which occupies a range of scrubby and intervening agricultural habitats in dry intermontane valleys in Colombia and northern Ecuador. The Green-capped Tanager, as discussed above, is found only in the watershed of a single high-lying arid valley in Peru. And the Lesser Antillean Tanager, found only on St Vincent and Grenada, occurs in gardens and semi-open areas but also in secondary growth and drier woodland.

The use of different habitats by separate geographical populations of the same species is a phenomenon that has not, so far as tanagers are concerned, received much attention from scientists and is complicated by the uncertain taxonomic status of some taxa. In many cases, a single tanager species occupies essentially similar habitats throughout its range, even though its populations are broadly dispersed geographically, but separate populations of a few species are found in two or more distinctively different habitats. The Orange-headed Tanager is an example of such a species that occupies different habitats in different portions of its range. Along the Orinoco River in Venezuela the race *orinocensis* is known mainly from young vegetation on river islands, and in western Amazonia the subspecies *chrysopis* also occurs in young vegetation such as *Gynerium* grass, willows (*Salix*), *Tessaria* (Asteraceae), *Cecropia* and *Erythrina* on river islands, as well as in young second growth along riverbanks and in humid shrubby clearings and gardens. South of the Amazon Basin, however, the nominate race of the Orange-headed Tanager inhabits dry woodland, parks, gardens and *cerrado*, as well as light woodland along watercourses; in north-western Argentina it is found in dry, strongly seasonal open woodland, and in vines, weedy scrub and brush along intermittent riverbeds in the lowlands and foothills, and here it ranges up to 1000 m elevation. In another example, the Black-goggled Tanager (*Trichothraupis melanops*) has one population in the Andes and another in the lowlands of south-eastern Brazil, and the two populations are separated by a wide gap. The habitats occupied by these two populations are quite different. Andean birds are found in a narrow band between about 1000 m and 2400 m on the eastern slope in Peru and Bolivia, where they occur at low density in the lower and middle strata of mossy forest on steep slopes, and pairs or families accompany mixed-species flocks that contain other species of tanager. The somewhat more numerous eastern population is found in both lowland and foothill forest in Atlantic eastern Brazil, east Paraguay and north-eastern Argentina, in this region reaching a maximum elevation of 1200 m, only slightly higher than the lowest elevation reported for this species in the Andes. While the eastern population is found in predominantly humid forest, the Atlantic Forests are more seasonal, warmer, and less humid than the cloudforests where the Andean population lives. A disjunct distribution also characterizes the Fawn-breasted Tanager, with an almost wholly Andean population (race *venezuelensis)* stretching from northern Venezuela south to Bolivia, as well as occurring locally in the highlands of southern Venezuela. These highland birds are found in a range of humid forest types, including forest borders, coffee plantations and disturbed or opened areas, and are nomadic or migratory, although their movements are poorly understood. A second, widely separated subspecies, the nominate race, is found in the Atlantic Forests of southern Brazil, Paraguay and Argentina. This south-eastern population occurs in both lowland and humid montane hill forest, but seasonally ranges into more open sites as far south as the *pampas* of Buenos Aires and northwards into mixed *cerrado* and dry forest in south-central Brazil. These habitats are far more open than any used by the Andean population of this species.

Disjunct or non-contiguous populations are a feature of many tanagers both in the Andes and in the lowlands of South America. In some cases, such as those of the Orange-headed, Black-goggled and Fawn-breasted Tanagers mentioned above, as well as the Blue-necked Tanager, these discontinuous ranges may be associated with habitat shifts that occurred in the past. From a modern perspective, the separations appear to be maintained by intervening habitat that is inappropriate. In another example, the Plumbeous Euphonia (*Euphonia plumbea*) occurs primarily in semi-open scrub in white sandy-soil regions, and its isolated and widely scattered populations across northern South America correspond closely to ancient deposits of these sands, some of which in western Amazonia predate the uplift of the Andes. The unravelling of historical events and corresponding time periods that may have led to such distributions is, however, difficult, and it may be almost impossible, even with the aid of molecular genetics, to reconstruct with confidence the reasons why some

Of 35 ***Hooded Mountain-tanager*** *stomachs examined, 34 contained only vegetable material and only one contained both animal and vegetable matter. As well as fruit pulp, the vegetable material consisted of seeds and leaves. These mountain-tanagers forage in two different ways. When in association with caciques* (Cacicus) *and jays (Corvidae), they move rapidly, roaming over large areas. They rarely mix with smaller species. Away from mixed flocks, they are slower and more methodical, hopping along bare or mossy branches, mainly in the middle and upper strata of trees.*

[*Buthraupis montana cucullata*, Ecuador. Photo: Kathy Kinnie]

disjunctions have occurred or why a once continuous population may have become separated into two or more in the past. In a common disjunct pattern among tanagers, a widespread population occupies humid forest across much of the Amazon Basin and a narrowly constricted population is confined to a band of coastal or montane forest in south-eastern Brazil. This distributional pattern can be observed with the Red-legged Honeycreeper, Green Honeycreeper, Yellow-backed Tanager, Flame-crested Tanager, Turquoise Tanager, Opal-rumped Tanager, Red-crowned Ant-tanager and Magpie Tanager. It is a feature also of the Orange-bellied Euphonia, Violaceous Euphonia (*Euphonia violacea*), Golden-rumped Euphonia (*Euphonia cyanocephala*) and Blue-naped Chlorophonia (*Chlorophonia cyanea*), species currently included in Thraupidae but now believed to be fringillids. An even commoner pattern of disjunction can be seen in the Andes, where populations widespread historically during cooler periods have, during a subsequent warmer epoch, been pushed to higher elevations and ultimately become separated by deep, arid and often hot valleys that become barriers to the free dispersal of species northwards and southwards. In some cases populations have, by various means, overcome these barriers. More often, however, widespread populations have found themselves isolated as climatic changes reduced appropriate habitat to a series of island-like ridges or mountain tops, with little or no chance for gene flow to occur between the various isolates. The Andes harbour many such distributional patterns, and dozens are evident from an examination of the tanager range maps. An example is provided by the Golden-crowned Tanager (*Iridosornis rufivertex*), a high-Andean species now separated into at least four and possibly as many as seven isolated high-elevation populations scattered between Colombia and northern Peru. Almost certainly this species was more widespread when climates were colder and its preferred cold, damp habitat was more extensive and continuous at lower elevations. Now, with its range fragmented, there is effectively no opportunity for gene flow between the populations, each surviving in refugium-like, wet elfin woodland at or near the tree-line. Other examples of tanagers with similarly fragmented ranges include the Superciliaried Hemispingus, Lacrimose Mountain-tanager (*Anisognathus lacrymosus*), Buff-breasted Mountain-tanager (*Dubusia taeniata*), Hooded Mountain-tanager and Black-chested Mountain-tanager. In some of these examples, isolation has been followed by minor plumage changes. In the case of the Buff-breasted Mountain-tanager, plumage differences also are accompanied by dramatic vocal differences north and south of the Marañon Valley. In some instances, isolation over time has resulted in populations that have diverged, approaching or reaching the threshold for recognition of the forms as separate full species, as has probably occurred with the various isolates of the Black-eared Hemispingus (*Hemispingus melanotis*), and the closely allied Piura Hemispingus (*Hemispingus piurae*) and Western Hemispingus (*Hemispingus ochraceus*), and with isolates of the Buff-breasted Mountain-tanager mentioned above. A similar situation can bee seen with Carmiol's Tanager (*Chlorothraupis carmioli*) and the Olive Tanager (*Chlorothraupis frenata*), taxa traditionally treated as conspecific. Both, incidentally, are now regarded as better placed within the cardinalids (see Systematics).

General Habits

Tanagers, irrespective of taxonomic definition, are an important and conspicuous component of almost every avian community in the humid New World tropics. To most humans, the general behaviour of the ones likely to be seen in settled areas must seem fairly unremarkable. Blue-grey (*Thraupis episcopus*) and Palm Tanagers, at least at first glance, appear to forage and behave in much the same way as many other small birds, and *Ramphocelus* tanagers troop around in noisy and familiar groups in gardens and bushy areas. Some of these same tanagers occasionally damage fruit in gardens, but they also eat many harmful insects (see Relationship with Man).

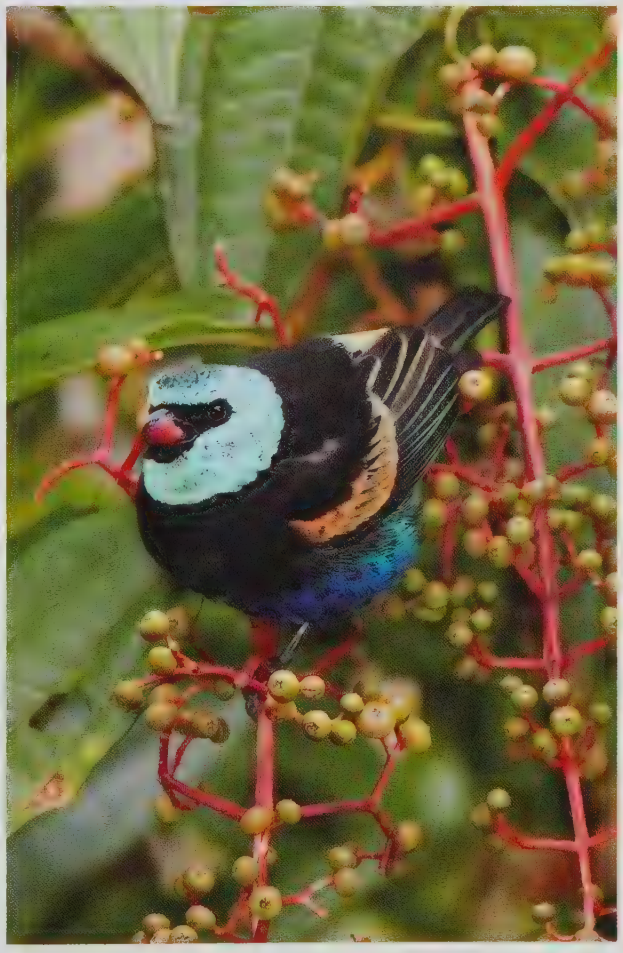
During at least part of the year, many tanagers join mixed-species foraging flocks and are found in pairs or families within these flocks. A minority also gather in much larger groups numbering 5–20 individuals, sometimes more, and when these forage with other species they may comprise 30–50% of all the birds in such mixed flocks; examples of this include the Beryl-spangled and Silver-throated Tanagers in the Andes and the Paradise and Green-and-gold Tanagers in Amazonia. Except when they are breeding, some tanagers occur also in wide-ranging flocks of their own species. For example, the Crimson-backed and Silver-backed

*The **Brassy-breasted Tanager** lives almost entirely on small fruits, topped up with a small quantity of arthropods. The feeding habits of this species and the Cinnamon Tanager* (Schistochlamys ruficapillus) *were studied over twelve months in Ibitipoca State Park, in Minas Gerais, Brazil. Both species consumed mainly fruit, but the two showed different responses to changes in food availability. When fruit was in short supply, the Cinnamon Tanager consumed more arthropods, leaves, flowers, and food left by tourists. But the Brassy-breasted Tanager maintained its high intake of fruit, with some arthropods, flowers and nectar, throughout the year.*

[*Tangara desmaresti*, Nova Friburgo, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Tanagers, as well as most other *Ramphocelus* tanagers, are among the most conspicuous birds in gardens, in settled areas and along forest and lake borders in lowland tropical America. They spend much of the year in little flocks, foraging, mobbing predators and even roosting together. These groups are presumably composed of related adults and offspring of these families, and perhaps also unrelated members, although the social organization of these ubiquitous flocks remains unstudied. Red-billed Pied Tanagers and Scarlet-throated (*Compsothraupis loricata*) and White-capped Tanagers (*Sericossypha albocristata*), although less well known because they occur in remote areas, also travel in groups of a few to a dozen or more individuals of their own species and roam through forest treetops. At times, Blue-grey, Sayaca (*Thraupis sayaca*) and Palm Tanagers also gather in loosely associated flocks. The reasons why these single-species flocks form are poorly understood, but this flocking behaviour may, at various times, be related to short-distance seasonal movements in response to changing food availability, to locally abundant food resources, to dispersal of the young, and to long-distance migration. In eastern Bolivia, for example, groups of 50–60 Sayaca Tanagers are commonly observed in Noel Kempff Mercado National Park in July and August and likely represent roosting and/or migratory parties from more southerly latitudes. In general, flocking, in whatever form, is most closely associated with species that occur in forested or partly wooded or shrubby areas. In contrast, species such as the Black-faced, Burnished-buff and Scrub Tanagers, which live in relatively open habitats, infrequently follow mixed-species flocks but are often seen in small, single-species groups that may consist of extended families.

The most extensive work on the display behaviour of tanagers has been conducted by Moynihan, who worked primarily in Panama with Crimson-backed Tanagers (*Ramphocelus dimidiatus*) and Lemon-rumped Tanagers, which share many similar types of display behaviour. His studies focused also, for brief periods of time, on several South American species of *Ramphocelus*, as well as on *Chlorospingus* bush-tanagers in Panama. Moynihan observed display behaviour associated primarily with locomotion, gregariousness, hostility and sexual behaviour of adults and juveniles, and found that all or most of the displays of Crimson-backed Tanagers, described below, were partly or completely homologous with those of Common Bush-tanagers.



Like most small passerines, Crimson-backed Tanagers perform various stereotyped wing-flicking and tail-flicking movements when they are about to fly. These are performed by males, females and juveniles with equal frequency and in all social situations, including by solitary individuals, and by birds in mixed flocks as well as those in single-species flocks. As with many other tanagers, these movements are most pronounced when a tendency to fly is inhibited or delayed momentarily, in which case the wing-flicking and tail-flicking probably serve as a signal of an individual's intention to fly. Wing-flicking movements of Crimson-backed Tanagers are similar to those of many other birds, and involve opening and closing the wing rapidly and repeatedly. Wing-flicking is almost always performed in synchrony with tail movements, but is generally less exaggerated. Tail-flicking usually involves the jerking of the tail sharply to one side, and then more slowly returning it to its original position; less often, the tail is flicked first to one side, then to the other and finally back to its initial position. Tail-flicking can also be vertical, involving simple down-and-up or up-and-down movements, or a more complex down-up-down movement, or vice versa. Simple down-and-up tail-flicking is the commonest movement.

Crimson-backed Tanagers are gregarious although somewhat less so than some other species of *Ramphocelus*. A family of four or five individuals often remains as a unit for months, but larger groups, involving several families, are apt to be less stable and much briefer in duration. With these tanagers, gregariousness is associated with a variety of hostility displays towards group-members and, to some degree, with rather weakly developed territorial defence or maintenance. Intraspecific disputes often involve an "erect" posture with the neck extended upwards, but the head horizontal, with sleeked plumage and slightly cocked tail. More aggressive postures include crouching and ruffling of the plumage. Plumage-ruffling, especially, is associated with a tendency to attack and often precedes fights that involve physical interactions. Gaping, in which the bill is held open unusually wide in a stereotyped position, is also commonly associated with aggressive behaviour and may be combined with crouching and ruffling; it perhaps represents an exaggerated form of threat biting, in which a threat posture is followed by a physical attempt to bite.

Simple monosyllabic nasal notes are given by adults and juveniles especially in social situations, when two or more birds are

The berries of Miconia *and related genera in the Melastomataceae comprise a significant proportion of all the fruit eaten by* Tangara *tanagers. In almost any month of the year, one or more species of this small tree can usually be found in fruit. In a study in Colombia, consumption of* Miconia *berries by 23 resident tanager species varied from around 14% of all fruit-eating in February to nearly 65% in December. In Trinidad, 31% of the fruits eaten by the* ***Turquoise Tanager*** *(above left) were* Miconia *berries, although this species has been recorded as eating 26 species of fruit. Insect-seeking, however, made up almost half the foraging records for this species. The* ***Gilt-edged Tanager*** *(above right) usually forages from the middle to the canopy of forest trees, but descends to feed at fruiting shrubs along the forest edge. The* ***Blue-necked Tanager*** *(below left) is primarily a fruit-eater: of ten stomachs examined, nine contained only fruit and seeds. Insects account for 13% of its diet in Colombia, the remainder being fruit, of which* Miconia *species comprise just over half. Although not often seen in mixed flocks, it may join them at fruiting trees. But the* ***Spangle-cheeked Tanager*** *(below right), which takes a wide variety of small fruits, is often found in small mixed-species flocks.*

*The **Golden-collared Honeycreeper** has sometimes been placed in the genus* Tangara. *Its montane distribution mirrors that of many* Tangara *species, and its plumage is much like that of the Black-headed Tanager* (T. cyanoptera), *although its bill shape differs substantially. It forages mainly in the upper levels of trees, and, typically, one or two associate with fast-moving mixed-species flocks containing* Tangara *and other tanagers. But observations suggest that it takes fewer insects than do* Tangara *species. It has been recorded as taking* Miconia *berries (as here),* Cecropia *catkins and nectar.*

[*Chlorophanes pulcherrimus pulcherrimus*, Cock of the Rock Lodge, Manu National Park and Biosphere Reserve, San Pedro, Cuzco, Peru. Photo: Roland Seitre]

present, and the calls often are not closely associated with particular types of behaviour. Nasal notes are uttered most frequently in certain types of hostile interaction, especially intraspecific territorial disputes, but not when actually fighting. Moynihan argues that nasal notes, in most situations, are given when escape and attack tendencies are roughly balanced and they thus represent a neutral situation perhaps slightly favouring escape over aggression, but are not uttered during actual escapes. They also are given very frequently when eggs or young are being threatened by predators. During these situations, the frantic calling and flying back and forth by the adults represent both escape and attack intentions, commonly referred to as "mobbing". Similar calls and mobbing behaviour are widespread among small birds. Crimson-backed Tanagers also utter a wide variety of other calls, ranging from muffled notes to hoarse notes that are associated with "flight or fight" tendencies. The entire spectrum of muffled to hoarse notes is associated with hostile situations, muffled notes representing the weakest hostile motivations, and hoarse ones the strong motivations; the latter are often uttered as threats, when attack and fight tendencies overwhelm escape tendencies. Combinations of muffled and hoarse notes may be involved in "greetings" between mated individuals, especially when the partners have been widely separated and then come unusually close together. Even in this case, however, the notes contain hostile components, although in these situations weaker muffled notes are predominant. Single plaintive notes also are used in various situations, but most often by partners that have become separated. These plaintive notes always stop as soon as a calling bird is joined by its mate.

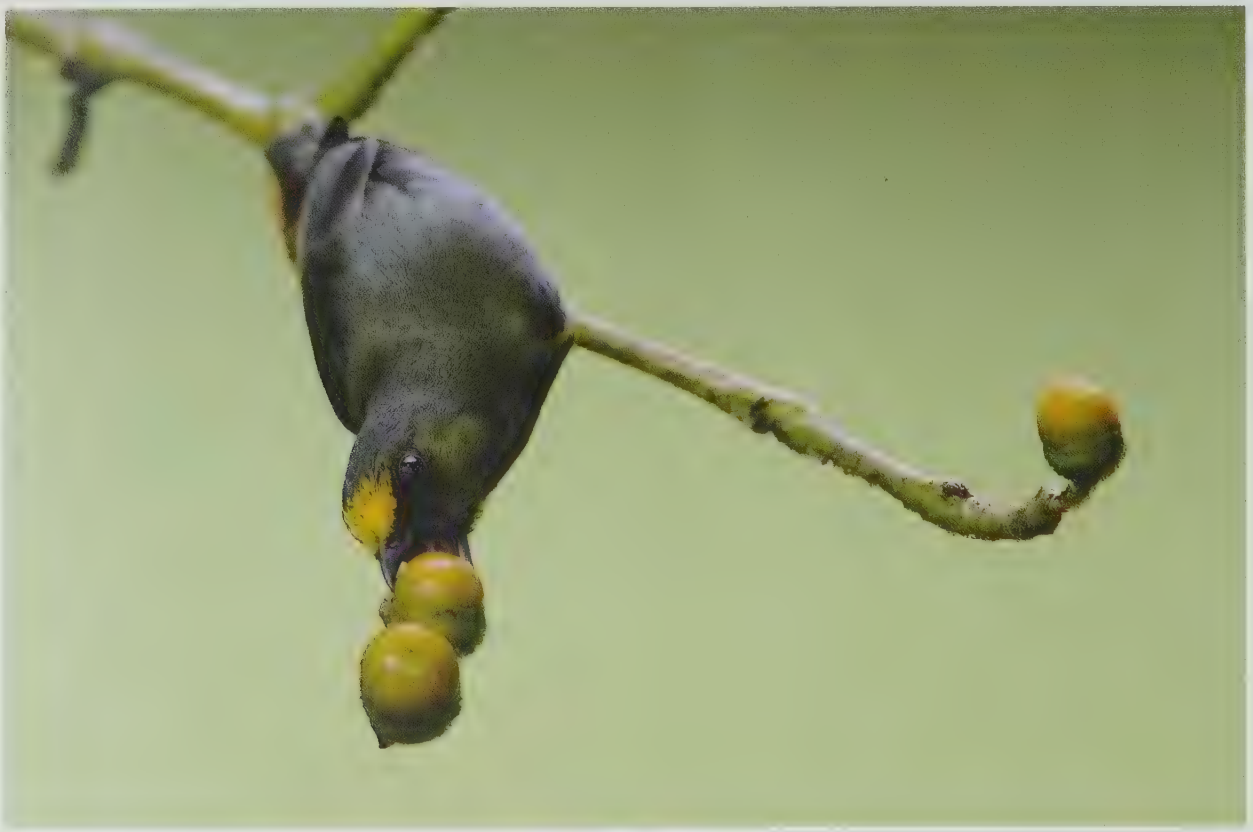
Dawn songs, which in fact begin well before dawn, represent the most sustained vocal effort of Crimson-backed Tanagers and are given only by males. Song perches are usually well elevated and exposed, so the singer is visible from all directions and he begins to sing the moment he arrives. Dawn-song postures of the Crimson-rumped Tanager are somewhat ritualized, being more rigid than during singing at other times, and the singer typically adopts a diagonal attitude, sometimes also with some fluffing of the breast and belly feathers. Dawn song is not accompanied by flicking of the wings or tail, although males typically fly back and forth between several song perches during their dawn performance. Dawn singing, in terms of behaviour, is a solitary exercise, almost always performed by single males. If a female is within 6–10 m the male seldom sings, and he always stops singing immediately if a female joins him. As with many species, dawn singing is largely confined to the breeding period. Males are frequently joined by their mates at some point during the dawn chorus but, according to Moynihan, these interactions are more likely to relate to pairing or pair-bond maintenance rather than copulatory behaviour. For both male and female Crimson-backed Tanagers, pre-copulation behaviour is characterized by a rather exaggerated bill-up and tail-up posture, with the wings raised, the tail quivering and the breast and rear-end feathers widely fluffed. Males assumed this posture both when distant from and when close to females, and females usually adopted the same posture at the same time if copulation ensued.

Relatively little has been written about the roosting behaviour of tanagers, and most of what has been written comes from the careful observations of Skutch in Costa Rica. There is considerable variation in roost-site preference from species to species, but Skutch noted one prevailing pattern. Tanagers that build open nests sleep amid foliage, the members of a pair often roosting from a few centimetres to a metre or so apart, but never in physical contact. On the other hand, Bananaquits and *Chlorophonia* and *Euphonia*, the last two genera now generally treated as fringillids (see Systematics), build domed and covered nests, and all seek more sheltered sites for roosting. They may utilize the nest itself as a roosting site, either intermittently or continually for surprisingly long periods of time. Female Bananaquits often sleep in their nests, and both sexes sometimes construct dormitories, which are similar to the nests but thinner and less well constructed. Small pockets of moss on limbs, and nooks and holes amid ferns, orchids, lichens, liverworts and other epiphytes growing on branches, may also be used as sleeping sites. Skutch once observed a male Tawny-bellied Euphonia that roosted within a mass of moss that hung beneath a horizontal branch 5 m up in a row of calabash trees near his house. The euphonia slept in a small side-facing pocket in this moss, a site that did not differ greatly from a typical nest-site. The bird was first noticed roosting in this moss pocket on 22nd September, and it returned every night until at least mid-October. About a year later, what was presumed to be the same male Tawny-bellied Euphonia roosted for several months in nearby calabash tree, this time in a

small space between fern rhizomes and a branch that was covered with small epiphytes. After roosting in several sites in this tree, the euphonia disappeared, but it (or perhaps another individual) returned a few years later and again roosted beneath a horizontal branch, this time on the thin root of an epiphyte that was sheltered by liverworts. Except for a few brief absences, this bird returned to the same roosting site every night for the next four months, always arriving silently and unobtrusively. Skutch also observed a female sleeping in a similar pocket amid liverworts growing beneath a branch. He reported that, with only occasional absences, this female used this roost-site for two years. In one instance, Skutch watched a Bananaquit usurp the roosting site of a female euphonia, eventually filling the hole with grasses and causing the euphonia to abandon the roost-site.

During his long career of reporting on the lives of birds in the American tropics, Skutch found roosting Silver-throated Tanagers only three times, and in each case it appeared to be a solitary individual, because no mate could be located nearby. The roost-sites were small twigs and a leaf petiole located 2–3 m above ground, and with a large sheltering leaf overhead. The tanager returned to the same site for several nights, and in one case roosted close to a Rufous-tailed Hummingbird (*Amazilia tzacatl*) nest where a female was brooding her nestlings. Palm Tanagers, Blue-grey Tanagers and Golden-hooded Tanagers usually roost in pairs, the members often within a metre or two of each other but not in contact. In Costa Rica, Skutch observed a pair of Blue-grey Tanagers that roosted in an orange tree, sometimes sleeping on the long thorns present on the tree; from March until July the pair roosted about 2·8 m up in thick foliage, the two individuals always slightly separated from each other. On the island of Trinidad, pairs of Palm Tanagers have been observed to enter porches of buildings to roost on beams, a choice that must be learned and represents a "safe", predator-free, roosting site. Farther south, in Brazil, Sick has reported the use by groups of Violaceous Euphonias of dense clumps of mistletoe as roosting sites. A group of Cherrie's Tanagers, a species generally treated as conspecific with the Scarlet-rumped Tanager in the writings of Skutch, roosted for weeks in a dense hedge of *Stachytarpheta*, a shrub with spikes of purple flowers that grew in his yard. Away from houses and gardens, these tanagers roosted in tangles of bushes and vines at the edge of forest; other sites included a thorny orange tree, which they shared with other tanagers. In January, in the Maracaibo Basin of western Venezuela, Hilty watched nearly 30 Crimson-backed Tanagers at dusk as they flew over a brick wall and into a small group of citrus trees behind a house, in what appeared to be a large communal roost.

The Bananaquit is widely known for its habit of building dormitory nests for sleeping, and euphonias usually sleep in small pockets of moss on the sides of or beneath branches or in other protected crevices. So far as is known, however, most tanagers do not make use of holes or dormitory nests or other special structures for sleeping.



Anting by birds is an activity in which a bird grasps an ant or other small arthropod and mashes or otherwise damages it, and then brushes or rubs it through its feathers. It has been reported for more than 200 species of bird, covering many families, but it has not been frequently reported for tanagers. Skutch mentioned the anting activities of the Green Honeycreeper and noted that, unlike in temperate latitudes, where anting usually takes place on the ground, it is almost invariably performed in Costa Rica by birds perched in trees. In Brazil, Sick summarized the anting behaviour of three species of *Tangara* tanagers, the Gilt-edged (*Tangara cyanoventris*), Brassy-breasted and Blue-necked Tanagers, and also that of the Golden-chevroned Tanager (*Thraupis ornata*), but said little about when and where the behaviour was observed. Anting by birds is generally regarded as a beneficial activity, although the specific role that crushed ants or other arthropods and their body chemicals play when rubbed on feathers or skin remains largely conjectural. It is believed to be somehow useful in feather maintenance by helping to rid the feathers of mites and other parasites or to reduce skin irritations that could occur during the moult period. Because it has been reported for so many birds, it is an activity that is likely to be practised, at least occasionally, by many more species of tanager.

Unlike anting, water-bathing has been reported for numerous species of tanager, and is an activity that is probably undertaken by all thraupids when they have the opportunity to do so. There appears to be little evidence that bathing is more typical of certain genera or species of tanager than of others, or that it is more common among species living in one habitat than among those in another. In humid lowland sites in tropical America, several species of tanager have regularly been observed to bathe, especially

In a study of eight species of epiphyte-searching insectivores from various families in Costa Rica, the only thraupid, the ***Sooty-capped Bush-tanager****, was the most vocal, conspicuous member of the guild, and most mixed-species flocks seemed to organize around it. The Sooty-capped Bush-Tanager used the widest range of substrates and was the only species constantly to feed on fruit. As well as* Miconia, *it eats the fruits of* Fuchsia, *blackberries* (Rubus) *and Ericaceae. It forages from near the ground to the middle of the canopy, most commonly at 3–6 m, and is restless and active, habitually flicking its wings and tail.*

[*Chlorospingus pileatus*, Savegre Lodge, Costa Rica. Photo: Theodoulos Poullis]

Tanagers either swallow smaller fruits whole or mandibulate them with the bill. The ***Olive-backed Euphonia****, seen here plucking a fruit, frequently feeds on* Lycianthes sancta-clarae*, a member of the nightshade family (Solanaceae) with a fruit measuring 12 × 10 mm, bigger than the bird's head. The euphonia squeezes out the pulp and drops the skin and most seeds. Euphonias and chlorophonias are the only tanagers with a digestive tract modified for the quick passage of fruit pulp. Both genera are now generally placed within Fringillidae.*

[*Euphonia gouldi praetermissa*, Costa Rica. Photo: Mike Danzenbaker/ AGAMI]

late in the afternoon on hot sunny days, and the activity has been recorded also for several species of *Tangara* inhabiting the wettest cloudforests. Whether bathing takes place more frequently in hot lowland habitats than in cool, humid montane regions is unknown, although some anecdotal observations suggests that this may be true. Skutch reported bathing by numerous species in humid lowland forest in Costa Rica, and Hilty has observed bathing by a wide range of tanagers, including euphonias, several species of *Tangara* and the Green Honeycreeper, in cloudforests of the western Andes of Colombia, as well as by members of the genera *Thraupis*, *Ramphocelus*, *Tachyphonus*, *Coereba* and *Euphonia* at small pools in streams and rocky outcrops in the middle Orinoco region of southern Venezuela and near the River Magdalena, in central Colombia. Bathing sites utilized range from small forest or streamside pools, usually at the edge of forest or in a small opening but near cover, to water-filled tree holes, broken branch stubs, knotholes on limbs or trunks and tank bromeliads in trees. In general, highly arboreal species, such as *Tangara* tanagers, bathe at sites in trees, rather than descending to the ground, whereas species that occur in shrubby forest borders and clearings, such as the White-lined, Blue-grey and Palm Tanagers and various species of *Ramphocelus*, readily bathe in pools on the ground. Bathing can be a solitary activity, as when it takes place at a small bromeliad or knothole in a tree, but at larger streamside pools it is more often a social activity with several species of tanager and other bird species in attendance and bathing simultaneously or waiting nearby.

The bathing activities of tanagers have been observed mostly between mid-morning through to the late-afternoon hours. While not confined to periods of sunny conditions, bathing may occur more frequently on warm sunny days. Bathing tanagers, like most small passerines, usually stand in shallow water to a depth of 2–5 cm or so and repeatedly dip the body and head forwards and downwards into the water while holding the wings and tail partly spread. While dipping the head into the water they rapidly flick or fan their wings, thus creating a cascade of splashing water drops that aids in wetting the bird's feathers. Following a session of bathing, which can last from a few seconds to a minute or more, and may include repeated wing-flicking and wing-fanning with much splashing, the bird flies to a nearby perch and fans its wings vigorously, and then preens for up to several minutes.

Many tanagers readily mob predators, often joining excited groups of birds that include hummingbirds (Trochilidae), tyrant-flycatchers, gnatcatchers (Polioptilidae), parulid warblers and emberizids. Small owls, especially those in the genus *Glaucidium*, are frequent targets of mobbing activities, as are arboreal snakes. Cats (Felidae), opossums (Didelphidae), raccoons (*Procyon*), rodents and other small mammalian predators, and even some small hawks (Accipitridae), may also be mobbed when the opportunity presents itself. Mobbing alarm calls seem to be universally recognized by all small birds and, although most mobbing activity is generally limited to harassment, including a constant stream of excited alarm calls, wing-flicking and hopping and flying back and forth in the vicinity of the predator, attacks involving physical strikes by tanagers and other species in an attempt to drive a predator from the area do occur at times. Small owls, once they fly, are almost always pursued for varying distances by a swarm of agitated small birds. In the northern portion of the Andes, various flowerpiercers, *Hemispingus* tanagers, Blue-capped and Blue-and-yellow Tanagers, and Lacrimose and Buff-breasted Mountain-tanagers have frequently been observed to mob Andean Pygmy-owls (*Glaucidium jardinii*). In lowland areas of northern South America, Crimson-backed and Silver-beaked Tanagers, White-lined Tanagers, and Blue-grey, Glaucous (*Thraupis glaucocolpa*) and Palm Tanagers, as well as Bananaquits and various species of euphonia, dacnis and *Cyanerpes* honeycreepers, all readily mob Ferruginous Pygmy-owls (*Glaucidium brasilianum*).

Although the majority of tanagers occur in pairs when breeding, their post-breeding behaviour varies considerably. Skutch believed that Grey-headed Tanagers remained in pairs throughout the year, although territoriality was weak, as might be expected for a species that follows a mobile food resource, in this case prey flushed by army ants (see Food and Feeding), and must frequently trespass through the areas of neighbouring conspecifics to reach such an unpredictable resource. Silver-throated Tanagers, a forest-based species, were seen in pairs all year, but Skutch believed that, when these tanagers were not breeding, pair-bonds were looser than those of some other tanagers. He also frequently saw solitary individuals, especially towards the year end, but it is not certain if this indicates an absence of pair-bonds. Cherrie's Tanager, like all *Ramphocelus*, occurs in noisy, conspicuous flocks

Many species of tanager include Cecropia *catkins in their diet, either throughout the year or seasonally. The* ***Bay-headed Tanager*** *readily hangs head downwards to eat the catkins and takes tiny protein corpuscles from the petioles. In a community of 41 species of tanager in western Colombia, 17 species were recorded as feeding in every month on the catkins of* Cecropia reticulata. *Usage peaked in October, when 25 tanager species were recorded as feeding at these trees. In a similar study of bird use of* Cecropia *in Espírito Santo State, in Brazil, visits peaked at dawn, midday and mid-afternoon, suggesting a "three meals a day" feeding pattern.*

that wander along forest borders and in overgrown clearings when not breeding, but mostly form pairs when breeding. Curiously, Skutch was unable to detect any behaviour by this species that seemed directly associated with pair-bond formation or courtship. Furthermore, territorial defence was essentially non-existent, conflicts among individuals were rare, and even the location of dawn-song perches seemed to bear little relationship to nest locations, which often were well separated but occasionally quite close together.

The social behaviour of Golden-hooded Tanagers proved even more puzzling to Skutch. Most nestings involved pairs, although one or two immature or adult-plumaged birds were present as helpers at some nests (see Breeding). Outside the breeding season, Skutch sometimes observed pairs, trios or even four adult-plumaged individuals travelling together and once observed up to 17 roosting together in two adjacent trees, including eleven together on one low branch. Extended periods of conflict between two individuals at the start of the March–April breeding period suggested that pair-bonds were reformed, or contested, at the onset of breeding. In western Colombia, observations by Hilty of colour-marked Golden-hooded Tanagers suggested a more stable social organization. Of four birds marked for twelve months or longer, all were present at the end of the study, and five birds marked for nine months or longer were also present at the end of the study. Both members of a colour-marked pair ringed at the outset of the study remained together throughout 15 months of observation and were never recorded more than about 375 m from the original capture site. One member of a second ringed pair died shortly after having been ringed, and it was not until about 4–5 months later that the survivor was observed with a mate, an unringed individual. These two then remained together for the last five months of the study. During the months before the single bird found a mate, it wandered widely, up to 450 m or more from its original capture site. Once mated, this second pair rarely moved more than about 200 m from its nest-site. Of two nests observed, no helpers were seen at either.

In a study in west Colombia involving several hundred marked individuals of 17 tanager species, several colour-marked tanagers remained paired for twelve months or more. These were the Grey-and-gold Tanager, Rufous-throated Tanager, Blue-necked Tanager, Golden-hooded Tanager and Palm Tanager. Colour-marked pairs observed for up to six months included the Bay-headed Tanager and the Emerald Tanager, as well as the Yellow-green Bush-tanager (*Chlorospingus flavovirens*), a species not genetically close to the true tanagers.

The longevity of pair-bonds of Orange-bellied Euphonias, however, could not be established with certainty. Several pairs, involving a ringed individual and an unringed bird, could be recognized, but it was not known if the partners remained together beyond a nesting period. The comparative stability of montane populations in western Colombia contrasts with empirical observations of euphonias in lowland western Amazonia, where the Orange-bellied Euphonia and several other species form small mixed flocks, at least in drier months, and remain together for unknown periods of time when feeding on mistletoe berries in the forest canopy. It is not known if pair-bonds are maintained within these groups, or if their members are related, or move seasonally. One Amazonian species, the White-lored Euphonia (*Euphonia chrysopasta*), is routinely observed in pairs, both when nesting and when visiting fruiting trees. and it may form permanent or semi-permanent pair-bonds lasting over several years.

Voice

Numerous authors have remarked that the tanager family contains some of the most beautiful of all birds, but also some of the poorest singers. A great many do have songs that are squeaky and unmusical, and in some cases a true song is so seldom heard that it is almost non-existent. For a few species, a song has yet to be identified with certainty. Nevertheless, the vocalizations of many tanagers are distinctive, albeit often difficult for human ears to discern clearly. A minority have musical songs, and these may be simple repeated phrases, such as are commonly given by *Ramphocelus* tanagers at dawn, whereas other thraupids have remarkably complex songs that involve intricate and rapid phrases, precisely timed duets, and even trio and quartet singing. Morphologically, the syrinx of tanagers is similar to that of other oscine passerines and capable of producing a wide range of complex sounds. So far as is known, songs are always given at least by males and, in some cases, also by females, although females may sing briefer and perhaps weaker songs than those of their respective mates.

By whatever means one chooses to discuss vocalizations within this broad family, however, a caveat looms, and it is the changing taxonomy of the family (see Systematics). Many of the most gifted singers currently included in Thraupidae, those with melodious songs pleasing to the human ear, are species now regarded by many as being best placed in other families. For example, all members of the genus *Piranga*, which includes four species in North America and a few others scattered from Mexico to Argentina, are excellent singers, noted for their slow, rich, carolling songs not unlike those of some *Turdus* thrushes. All of them, however, appear to be genetically more closely related to cardinalid finches than to tanagers. The *Habia* ant-tanagers likewise have slow, sweet songs and they, too, appear to be unrelated to the true tanagers. The various species of *Euphonia* comprise another group in which some species have complex chattering songs, others a variety of simple whistles, and still others a great ability to mimic sounds, and the genus has sometimes been placed in Fringillidae in recent reclassifications. The Violaceous Euphonia, the Yellow-throated Euphonia (*Euphonia hirundinacea*), the Thick-billed Euphonia (*Euphonia laniirostris*) and, to a lesser extent, the Chestnut-bellied Euphonia (*Euphonia pectoralis*) all imitate calls and songs of other birds. Generally, their mimicked calls are accurate, although they are unlikely to deceive the original models because they are often given over and over in rapid delivery. The dawn songs of at least some of the *Chlorothraupis* tanagers, if not especially musical, are certainly notable for their energy and complexity, and *Chlorothraupis*, as well as the large assemblage of *Chlorospingus* bush-tanagers which have energetic, if rather simple, dawn songs, evidently shows closer genetic affinities to other families.

Stripped of some of the best singers in the family, many of which are being shipped off, taxonomically, to other families, what remains of vocal talent within the Thraupidae? For such a large and colourful family, the remaining species comprise, at present, a group whose songs, in large measure, have been described with such words as "high-pitched", "squeaky", "thin", "a high trill", "rapid", "monotonous", "high and strident", "excited bursts of ticking and twittering", "sharp, dry or buzzy", and so on. From the literature, it is clear that the songs of many tanagers are high-pitched and complicated, and difficult to paraphrase in a meaningful way. Furthermore, no comprehensive vocal analysis has been carried out for any tanager; no detailed studies have been made of the complete vocal repertoire, the functional and behavioural context of the vocalizations, sexual differences, and seasonal differences, nor of the ontogenic development of the vocal repertoire. Even the range of geographical variation in a thraupid's songs is largely limited to anecdotal comments, as, for example, when Skutch mentions that the Blue-grey Tanager, which he often called the "Blue Tanager", has developed song dialects, noting that in Carabobo, in Venezuela, the "song started off much like that of Costa Rican Blue Tanagers but it ran off into high, wiry notes like those of the Bay-headed Tanager—notes that I have not heard from the Blue Tanagers in Central America". For a surprising number of tanagers, especially in the genus *Tangara*, there is relatively little information: few archival sound recordings and few substantive qualitative written transcriptions of vocalizations. Vocal descriptions of *Tangara* are a particularly thorny problem, because it is often unclear which of their vocalizations actually comprises a song. For many species, it has proved difficult to distinguish true songs clearly from vocalizations that could denote greeting, excitement or other aspects of behaviour. Furthermore, the songs of many *Tangara* tanagers apparently are given infrequently, or they are so weak and high-pitched that they are infrequently heard or recognized as songs.

In general, the songs of oscine passeriforms are more complex, having more non-repeating notes or phrases, than the simple, often repetitive suboscine songs, and at least portions of oscine songs are learned, rather than inherited. While the songs of many tanagers could hardly be regarded as musical, they are often complex and, in some cases, trios, quartets and even quintets have evolved. Chief among tanagers engaging in these types of complex vocal choruses are several species of *Hemispingus*. It is uncertain if all members of this genus engage in group performances, but this behaviour has been reported for at least a third of them, including the Superciliaried Hemispingus, Oleaginous Hemispingus (*Hemispingus frontalis*), Rufous-browed Hemispingus (*Hemispingus rufosuperciliaris*), Black-headed Hemispingus (*Hemispingus verticalis*) and Drab Hemispingus (*Hemispingus xanthophthalmus*). There is no information on the function of these songs, nor on the context in which they are delivered. The performance of the Oleaginous Hemispingus is perhaps typical.

In a study of bird use of Cecropia *in Espírito Santo State, in Brazil, the species that tended to arrive first was the* ***Violaceous Euphonia*** *(seen here feeding in a* Piper aduncum *tree). It often sang, imitating the calls of other birds, as if calling them to the fruiting trees, perhaps to provide "safety in numbers" against predators. Rather than feeding for extended periods, birds tended to make repeated and rapid visits to* Cecropia, *as if wary of hawks (Accipitridae) that may wait in ambush near a busy fruit tree. The Violaceous Euphonia joins mixed groups of birds in mobbing small owls (Strigidae) and other predators.*

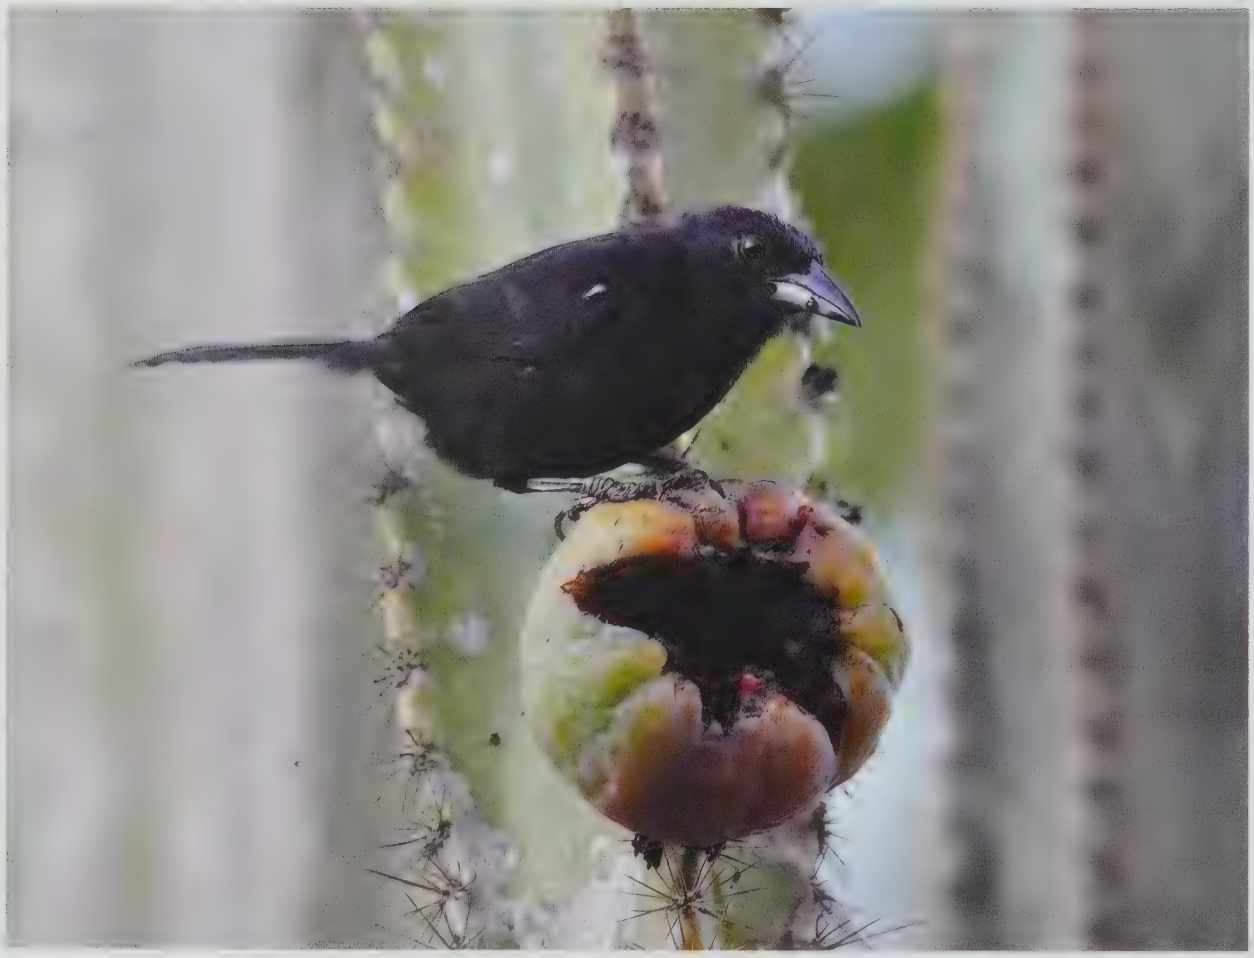
*The **Olive-green Tanager**, seen here feeding on the seeds of a bromeliad of the genus* Aechmea, *is most often found in single-species flocks, and is only occasionally joined by other passerines. When foraging, individuals within a flock often spread over a fairly large area. Only two other thraupids, the White-lined* (Tachyphonus rufus) *and Silver-beaked Tanagers* (Ramphocelus carbo), *are known to eat bromeliad fruits. But many species visit bromeliads in search of insects, either hopping around them and peering at them (as the Olive-green Tanager does), or rummaging through them.*



[*Orthogonys chloricterus*, Itatiaia City, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Pairs, trios or quartets of this species, while foraging relatively close together at dawn or shortly thereafter, periodically break into more or less simultaneous song, sometimes several times within a minute. One individual initiates the chorus, and the other singers, which may be only a metre or a few metres away, immediately join in, giving songs that are either identical or similar but sound as if slightly out of sync with that of the lead bird and perhaps also with those of neighbours. The audible effect of up to four birds more or less simultaneously giving a rapid stream of chipping notes is that of an intense chattering vibration that may accelerate slightly, and then gradually slow as the singers proceed. Unquestionably, the sound volume and vibration effects produced by four birds is greater than could be achieved by any single individual alone, although it is unclear how this is used in the context of the social units of these species.

Vocal duetting is performed by several genera of tanagers, including *Neothraupis*, *Cypsnagra*, *Thlypopsis*, *Hemispingus* and *Rhodinocichla*, and the structure of the environment in which each species occurs has shaped the way in which duets have evolved and are used in communication. For example, vocal duets are an important aspect of song performance of the White-rumped Tanager, a species of savanna with scattered trees (*campo sujo* and *cerrado*) in Brazil and eastern Bolivia. Duetting is well documented also for the enigmatic Rosy Thrush-tanager (*Rhodinocichla rosea*), a species that occurs in dense understorey in dry to humid scrub and forest borders from Mexico south to western Venezuela. While mated pairs of both of these species perform duets, they are given in dramatically different ways and, to some extent, for different purposes. Pairs of White-rumped Tanagers, for example, are conspicuous as they sit close together in the open in isolated low treetops or the tops of tall shrubs and sing loud rollicking duets in the early morning hours, and periodically during the day, to announce their territorial ownership. Males initiate these duets with a churring that changes to a low-pitched, staccato rattle, at which point the female joins in with a series of forceful and syncopated musical phrases that may be repeated several times, the overall effect being not unlike that of humans singing old-fashioned "rounds", but with a distinct syncopation in the performance. The contrast between the male's unmusical vocalizations and the musical part performed by the female is dramatic and unforgettable, and travels a long distance across open savanna. Between performances, the pair may fly off a considerable distance to other trees and repeat the duets and, if another pair enters its territory, the partners quickly and aggressively respond to the intruders. Rosy Thrush-tanagers, on the other hand, are retiring birds of dense undergrowth and are difficult to see, and they rarely or never sing from an exposed position of any kind, yet both males and females announce themselves with slow musical phrases. Pairs sometimes sing antiphonal duets from hidden positions in dense undergrowth, and do so even at the nest-site. Pairs of Rosy Thrush-tanagers may sing both solos and duets during territorial disputes, but vocal duetting remains only one of several vocal tools in territorial defence, and it appears to be employed much less often by this species than it is by White-rumped Tanagers. Antiphonal duets by thrush-tanagers are used extensively also in pair maintenance and mate location, as a means of keeping track of the partner in dense undergrowth, where pair-members are often out of sight of each other for extended periods of time. In this manner, the duet behaviour of thrush-tanagers resembles that of many *Thryothorus* wrens.

While the songs of tanagers, as noted above, are often described as being high-pitched and complex, general song types tend to be similar among species within the same genus and are, therefore, useful for taxonomic purposes and for identification of species in the field. Some examples within the family include the two species of *Schistochlamys*, which sing a rather lilting and melodic series of whistles that brings to mind the songs of some cardueline finches; *Hemispingus*, which give high, thin chipping notes when foraging and periodically perform vocal duets, trios, quartets, and even quintets that consist of a fast staccato series of chipping notes; and the small, warbler-like *Thlypopsis*, which sing high, wiry notes and bursts of thin "chip" notes that are given, at least by two species, as duets. The two *Creurgops* are vocal minimalists with only their calls, but not their songs, recorded. *Tachyphonus* comprises a less easily characterized group in which the males' songs are either a series of rather simple, flat rising and falling notes or much more complex, high-pitched songs, and, as noted previously (see Systematics), the genus is polyphyletic. *Lanio* is a small but vocally facile group of species with simple whistled songs, loud smacking contact notes and harsh, well-developed alarms; *Ramphocelus* tanagers deliver

Tanagers have few morphological features specifically for handling fruit. The Swallow Tanager (Tersina viridis) *is the only thraupid with a gape wide enough to swallow what are, in relation to its body size, even moderate-sized fruits. A few non-forest tanager species eat the fruits of* Cereus *cacti; these include the* ***Sayaca Tanager*** *(above) and its congener the Blue-and-yellow Tanager* (Thraupis bonariensis), *the* ***White-lined Tanager*** *(below) and the Silver-beaked Tanager* (Ramphocelus carbo). *The fruits of* Cereus *cacti are dehiscent, splitting open to expose the pulp and seeds. Tanagers mandibulate the pulp before swallowing it, and tend to move the seeds and any attached skin to the edge of their beak, and drop them. In a study in* restinga *habitat in south-east Brazil, only 3·5% of 145 seeds of the cactus* Pilosocereus arrabidae *regurgitated or defecated by Sayaca Tanagers germinated. Germination rates were much higher for the Purple-throated Euphonia* (Euphonia chlorotica), *which, like other euphonias, has a digestive tract adapted to process fruit pulp quickly while eliminating potentially poisonous seeds. The Purple-throated* Euphonia *is one of a number of Euphonia species which eat the fruits of* Rhipsalis, *a genus of epiphytic cacti which grow in the forest canopy. The fruits of figs* (Ficus) *are another important component of the Sayaca Tanager's diet. In a study in dry forest in western Brazil, 20 bird species were observed to feed on figs during the wet season. They ate an estimated 83,000 figs between them, and the Sayaca Tanager consumed 16% of the total. This increased to 27% of 85,000 figs during the dry season.*

*This **Fawn-breasted Tanager** is eating the fruits of* Eriobotrya japonica, *an exotic tree from south-eastern China which is rapidly colonizing some parts of Brazil, including the borders of the Atlantic Forest. The Fawn-breasted Tanager was one of a number of frugivorous bird species which, a study found, were entering Brazilian towns and cities to eat the fruit of this and other exotic trees and shrubs grown in gardens and parks. The study concluded that these birds could transport viable seeds of alien species in their gut and disperse them on their return to natural and semi-natural habitats, including protected areas.*

[*Pipraeidea melanonota melanonota*, São Lourenço do Oeste, Santa Catarina, Brazil. Photo: Rudimar Narciso Cipriani]

sharp chipping notes when foraging and sweet, melodious whistled songs at dawn and dusk; *Spindalis*, a Caribbean group of four species, has variable songs of sharp notes, ticking notes, harsh scolding notes and thin trills; and *Thraupis* tanagers give songs that are the quintessential high-pitched, squeaky songs for which the family is so well known. *Bangsia* is a vocally poorly known group, its members, so far as is documented, having high-pitched but rather simple repetitive songs that may consist of single or two-note phrases, buzzes or pulsating trills. In contrast, the songs of *Anisognathus*, the mountain-tanagers of the high Andes, are more varied and less easily characterized, but they are usually complex and include one or a few lower-pitched or forceful notes alternated with higher-pitched squeaky notes, or rapid and complex bursts of high and low notes, and, in one taxon, a series of melodious whistles that increase in volume and pitch. *Buthraupis*, another high-Andean group with what are, for the birds' size, surprisingly high-pitched and weak songs, utters phrases that consist of various squeals and "wheedles" and repeated single notes or phrases, as well as fast complex songs given in flight display. The genus *Tangara*, comprising over a sixth of the family as traditionally classified, gives songs that are, so far as is known, mostly quite high-pitched and vary from being a few simple notes to being wiry, complicated and sometimes pulsating verses, but the songs of most species are infrequently heard. *Diglossa* songs are generally characterized by their long-sustained, and often extremely complex and jumbled series of notes delivered rapidly; a few members of this genus have a song that is, instead, a flat trill. Other groups currently included in Thraupidae, although likely to be unrelated to true tanagers, exhibit similar generic song patterns. As mentioned in the preceding paragraphs, *Chlorospingus* bush-tanagers, for example, typically give fast bursts of chipping and twittering notes when excited, but their dawn songs are simple and repetitive, and *Piranga* species sing single, mostly simple melodic songs. *Habia* species are noted for their mellow whistled songs and rich vocal repertoires, although some have simple, repetitive and unmusical dawn songs.

Tanagers generally sing at dawn, although the extent of dawn song varies greatly and, in some areas, is almost certainly seasonal, too. Dawn songs of a few genera, such as *Ramphocelus* and *Thraupis*, which often live in the presence of humans, are well documented and often pleasing, or at least persistent. Dawn songs are reported for such varied genera as *Neothraupis*, *Thlypopsis*, *Habia*, *Thraupis* and *Tangara*, and probably are given by many tanagers. Some species, however, sing relatively little, regardless of the season or the time of day. The Magpie Tanager is one such example, as are many species of *Tangara*, and a number of primarily Andean genera of tanagers, including *Creurgops*, *Bangsia* and *Buthraupis*, although in some, perhaps many, cases the apparent lack of song may be an artefact resulting from an inability of human observers to recognize what constitutes a song in the species in these genera.

Dawn songs are typically delivered from a prominent perch, suggesting that maximum territorial coverage is the desired purpose of the performance. On the other hand, some species also sing day songs, which differ in various ways from those given at dawn, and these songs are more often given from lower and less visible perches. The function of day songs may vary with context, but it is more likely related to pair maintenance and contact between partners, although little is known about these songs. Far less often heard or witnessed are the flight songs and displays performed by a few mountain-tanagers. In the rare cases in which these have been observed, a complex song is given as the bird flies out on a circular or oval path over the canopy of mountain forest. Apparently, these aerial song displays can occur at any time of the day, and little is known about the context in which they are performed.

In addition to songs, given at dawn and sometimes periodically during the day, tanagers also have various calls. These include contact notes, which are almost invariably high-pitched and weak, and one or more kinds of alarm calls, which are usually sharp or harsh and lower-pitched than contact notes. Other vocalizations are used in various situations, especially in hostile or aggressive encounters, at or near nests, and during courtship, and include various harsh or scolding notes, rattles and high-pitched chipping notes, although the vocal repertoires of thraupids are poorly documented. Several mountain-tanagers in the genus *Buthraupis* emit distinctive calls prior to taking flight and during flight. These vocalizations may serve to communicate information to flock-members, which are sometimes well scattered.

Perhaps the most remarkable documentation of the dual role of vocalization was discovered during a study of mixed-species

A versatile forager that employs a range of techniques to catch insects, the Blue-grey Tanager also eats a variety of fruits. It plucks and swallows small fruits and berries while perched, but clings to larger fruits (like this papaya) and pecks out pieces. In a study in Trinidad, ***Blue-grey Tanagers*** *ate two kinds of fruits not generally taken by any other tanagers. They mandibulated the 1-cm-long berries of* Vismia *before swallowing them, but plucked the 5-cm-long catkin-like fruits of* Piper, *which they carried to a perch before laying them across a branch and eating pieces out of them.*

[*Thraupis episcopus episcopus*, Tailândia, Pará, Brazil. Photo: Edson Endrigo]

flocks in south-western Amazonia. Researcher C. A. Munn found that the White-winged Shrike-tanager employed alarm calls at the approach of predators, but occasionally gave false alarm calls to warn off a competing species if the outcome of an aerial chase for arthropod prey was close. This remains one of the few documented examples in which birds have been shown to employ calls for the purpose of deceit (see also Food and Feeding).

Lastly, it is worth reiterating that tanagers, as currently defined taxonomically, are far from being a monophyletic group, and discussions of their vocalizations, especially the notably deficient efforts of many species mentioned above, likely present a biased view of the family. Recent molecular studies, as summarized at the beginning of this essay (see Systematics), reveal that some cardinalids and numerous emberizids are closely aligned with tanagers. A significant number of these species will probably be transferred to the thraupid family and many of them are excellent singers, including especially the cardinals (*Paroaria*), saltators (*Saltator*), seedeaters (*Sporophila*), diuca-finches (*Diuca*), sierra-finches (*Phrygilus*) and yellow-finches (*Sicalis*) and even the warbling-finches (*Poospiza*). The outcome is likely to reveal an assemblage of birds more evenly balanced between species that have what are, to the human ear, pleasing songs and those possessing squeaky, unmusical songs.

Food and Feeding

Almost all tanagers live on a mixed diet of fruit and insects, and for some, including members of the genera *Coereba*, *Chlorophanes* and *Diglossa*, nectar is an important food item, at least seasonally. Species of *Thraupis*, *Chlorospingus* and a few others also eat some buds, as well as immature ovaries of flowers, and *Thraupis* tanagers include young leaves in the diet. With such a wide range of foods taken by members of this family, it is not surprising to find that there are numerous species with specialized foraging habits and feeding behaviour. There are, for example, species or groups of species that are almost wholly frugivorous, and others that are almost wholly insectivorous, or nectarivorous, or that consume combinations of these items. Using traditional taxonomic arrangements, there are no species of tanager that feed predominantly on seeds. Molecular-genetic studies, however, have modified ornithologists' understanding of family and genus limits of tanagers (see Systematics), and forthcoming taxonomic arrangements are likely to include within Thraupidae many species that eat mostly seeds or have a mixed diet of seeds and insects, including numerous genera from the high-Andean *puna*, from the scrub of Patagonia, from semi-open grasslands in humid New World tropical lowlands, from the Caribbean, and even from the Galapagos Islands.

Although many tanagers are widely considered to be mostly frugivorous, foraging data for those species studied in detail indicate that they consume a mixed diet of fruit and arthropods. The proportions of food items eaten can vary dramatically through the year in seasonal areas, but may vary little in humid areas. Species living in strongly seasonal habitats, such as places with lengthy wet and dry seasons, are apt to switch the diet in response to periodic shortages of certain resources. On the other hand, communities of tanagers in wet and relatively non-seasonal environments, such as the western slope of the western Andes in Colombia, and in western Amazonia, experience few resource shortages and their diets include fairly similar proportions of fruits and arthropods throughout the year. The composition, and possibly the quality, of the fruits taken, however, may change through the year. The manner in which tanagers search for insect prey and the substrates on which they search are often highly species-specific, and even the range of fruit sizes and the method by which fruits are handled vary among members of the family. Unfortunately, however, only a few formal studies have focused specifically on these aspects of tanager dietary strategies.

Isler and Isler, in their landmark treatise on tanagers, were among the first to attempt a family-wide synthesis of broad dietary patterns in the family. Bringing together information on fruit and insects, but excluding other dietary items, they compiled data from published and unpublished sources on 149 species of tanager. Their compilation included both formal studies of foraging behaviour and non-systematic observations from numerous observers over a broad geographical area. Despite some likely bias resulting from the greater ease of observing birds eating fruit compared with those consuming cryptic insects, the study reveals broad dietary patterns within the family. For example, the diet of 33% of the tanagers in their survey consisted of at least two-thirds insects, while the diet of 28% contained at least two-

Arillate fruits are often rich in both proteins and lipids, and attract a wide range of small frugivorous birds, including honeycreepers, dacnises and many Tangara *species. The* ***Red-legged Honeycreeper*** *regularly hangs head downwards, or completely upside-down, to obtain fruit or arils, and also hovers to extract arils from their woody coverings. In Trinidad, the tiny berries of* Miconia *species comprised 33% of all fruit taken by Red-legged Honeycreepers, which is typical of thraupid species, but the arils of arillate trees and vines accounted for an additional 35% of fruit material eaten.*

[*Cyanerpes cyaneus cyaneus*, between Cayenne and Saint-Georges, French Guiana. Photo: Damien Laversanne/ Bios]

thirds fruit. The remaining species, approximately 40% of the total, ate more or less equal proportions of insects and fruit. Perhaps the most significant finding was that fruit comprises half or more of the diet of approximately 68% of all tanagers as currently classified.

The first attempt to quantify foraging behaviour among a community of tanagers involved a 13·5-month study in Trinidad by B. K. Snow and D. W. Snow. This husband-and-wife team kept systematic records of the foraging behaviour of the 15 species of tanager and honeycreeper on the island in an effort to discover the extent of feeding overlap between the various species and to determine ways in which foraging behaviour differed among them. Of the 15 species studied, ten were relatively unspecialized morphologically, having a bill suitable for the exploitation of a wide range of small fruits and berries. The three honeycreepers and the Bananaquit had a bill specialized to varying degrees for the exploitation of nectar, and the dacnis possessed a sharp-pointed bill suitable for fruit, nectar and the capture of insects. The Snow team found that, among the ten unspecialized tanagers, some feeding-niche separation between the species was due to their exploiting different habitats, but more was due to a differential utilization of micro-habitats within a habitat. Among closely related species, feeding overlap was much greater in the portion of the diet that was fruit than in that represented by insects. Nevertheless, some important differences in fruits chosen were evident. Blue-grey Tanagers, for example, frequently ate compound fruits, items that other species rarely or never took, and White-lined Tanagers often consumed bromeliad fruits, a dietary item shared with Silver-beaked Tanagers. The three species of *Tangara* and the two *Thraupis* species were numerically the most important genera, and the Snows found that, compared with the *Tangara*, the *Thraupis* favoured non-forest areas, took more nectar and fewer fruits, foraged higher in trees, and sallied more for flying insects. They also pointed out that, while species that eat fruit are often numerically the most abundant, there were far fewer species of frugivore than of insectivore, a reflection perhaps of the fact that there are many more ways for insects to hide and hence more opportunities for specialization on them. Both of the two *Cyanerpes* honeycreepers searched for insects by using a "look-under-the-branch" technique, but the Red-legged Honeycreepers also searched foliage and frequently sallied for flying insects. Overall, insects comprised a much larger proportion of the diet of Red-legged Honeycreepers than they did for Purple Honeycreepers (*Cyanerpes caeruleus*), which relied more heavily on seasonal availability of nectar. Red-legged Honeycreepers included more fruit in their diet than Purple Honeycreepers, roughly 44% to 30% fruit respectively, but, because of the long narrow bill, neither species exploited more than three or four kinds of fruiting shrub, mainly species of *Miconia*, a smallish tree that often produces large crops of sugary but tiny berries. The Green Honeycreeper, a *Chlorophanes* species with a sharply pointed but much shorter bill than that of *Cyanerpes*, fed heavily on fruit and on small flying insects, which it captured in the vicinity of large flowers, whereas the Blue Dacnis took a wide variety of fruit and a roughly equal proportion of insects, but less nectar than any of the other thraupids in the study. The Bananaquit was highly specialized for nectar-feeding. It depended far more on nectar than any of the other species, and indeed this food source accounted for about 75% of its diet throughout the year. Not surprisingly, it fed on a much greater variety of flowers than any other tanager in the study. Fruit comprised a small proportion of its diet, and it pierced the majority of these fruits, whereas most other tanagers mashed or gulped fruits. Because the *Cyanerpes* honeycreepers fed on only a few nectar sources, their nectar consumption varied sharply during the year.

As most tanagers are small, they are capable of eating only small fruits which they can gulp whole, or mash and swallow piecemeal. Small fruits are usually high in carbohydrates, or sugars, but low in fats and proteins, and they do not, by themselves, comprise a balanced diet, unlike the large fat-rich and protein-rich fruits favoured by large-bodied, specialized, fruit-eating birds. Many tanagers consume large quantities of tiny berries, especially those produced by *Miconia* and related genera in the Melastomataceae family. An analysis of two species of melastomes showed that their berries consisted of 84% carbohydrate by dry weight, far higher than an average of 56% recorded from a sample of fruits in 26 other plant families. The implications of a diet of high-carbohydrate but low-quality fruits have led tanagers and most other small frugivorous birds also to include in their diets varying quantities of insects, which provide a source of protein. Perhaps no better example of a mixed diet can be found than that of members of the genus *Tangara*. The 49

The long, slender, decurved bill of Cyanerpes *honeycreepers is associated with specialized ways of consuming fruit, insects and nectar. Of observations of the* ***Shining Honeycreeper*** *(above) foraging in Panama, 44% were of fruit-eating, 37% were of insect-hunting and 19% were at flowers. The Shining Honeycreeper is sometimes aggressive towards the* ***Red-legged Honeycreeper*** *(on right in lower picture) and may displace it from food sources. Shining Honeycreepers, however, generally favour more humid regions, where seasonal swings in food availability are less pronounced than in the drier habitats used by Red-legged Honeycreepers. In Trinidad,* Cyanerpes *honeycreepers feed on only a few nectar sources, and so their nectar consumption varies sharply during the year. This differs markedly from the Bananaquit* (Coereba flaveola)*, for which nectar accounts for about 75% of the diet throughout the year. Nectar-feeding at flowers made up just 12% of observed foraging by Red-legged Honeycreepers in Trinidad. Overall, insects comprised a much larger proportion of the diet of the Red-legged Honeycreeper than of that of the* ***Purple Honeycreeper*** *(on left in lower picture), which relied more heavily on the seasonal availability of nectar. The Purple Honeycreeper takes a smaller percentage of fruit than the other honeycreepers, and its narrow bill probably precludes it from including many of the fruits that the other species eat. But Purple Honeycreepers occasionally use the beak to pierce and suck fruits such as oranges.*

or so species scattered from Mexico south to northern Argentina all have a mixed diet of fruit and insects. A few species also consume nectar and other vegetable items, but the quantity of these is negligible when compared with the amounts of fruit and insects taken.

While most tanagers include some fruit in their diets, these birds are well designed for capturing arthropod prey. Their morphological and behavioural adaptations represent a compromise between what is required for capturing insects and, at the same time, what is needed for efficiently harvesting a variety of small fruits and berries. Whereas the behaviour of some birds when hunting arthropods involves a stationary search, as illustrated by, among others, the jacamars (Galbulidae), puffbirds (Bucconidae), motmots (Momotidae) and certain tyrant-flycatchers, the foraging behaviour of all tanagers is characterized by movement, usually little sprints and pauses, as the individual progresses along a branch or twig or moves restlessly through foliage. Within this broadly defined category, however, tanagers make use of an extremely wide range of substrate specializations and employ an almost limitless variety of searching techniques with the aim of finding arthropod prey and, at the same time, avoiding excessive foraging overlap with other species, which would reduce prey-capture rates for all species involved.

The Isler husband-and-wife team enumerated ten broad substrates used by tanagers when foraging, as well as some of the methods utilized by the birds in order to obtain prey from these substrates. Since their preliminary survey, detailed observations by Naoki and others have shown that, in some tanager communities, subdivision of niche substrates extends well beyond these groupings. A sample of the major substrates utilized by tanagers includes the following twelve.

1) **Branch surfaces**. Many tanagers, both large and small and both in the highlands and in the lowlands, hop along branches, pausing frequently to inspect the sides or underside of branches. Smaller species often search in a very stereotyped or repetitive manner, larger species generally less so, and the category can include both large and small branches, twigs, bare branches, and partially or completely moss-covered or epiphyte-covered surfaces. A few species hang downwards from the sides of branches, and especially from moss and other plant material growing on the sides of these.

*The **Chestnut-bellied Euphonia** probes flowers for nectar and/or insects and also takes sugar water from feeders. Hovering is only a small part of a wider foraging repertoire for this species. Euphonias and chlorophonias both hover, but are less efficient at hovering than are hummingbirds (Trochilidae) and manakins (Pipridae). Their bills are short and rather thick, which may prevent them from reaching as far or as efficiently as species in these other families, and limit the range of nectar and fruit that they can harvest.*

[*Euphonia pectoralis*, Brazil. Photo: Kathy Kinnie]

2) **Leaf undersurfaces**. Tanagers in a number of genera search the undersurface of leaves, and a smaller number also regularly search upper surfaces (see next category) or both surfaces. To reach the undersurface of a leaf, most *Tangara* perch on a twig or leaf petiole, or cling to the leaf itself, and lean down to peer underneath. Some species, typified by the Red-crowned Ant-tanager and the *Chlorospingus* and *Cnemoscopus* bush-tanagers, hop quickly up slanting branches and twigs until they are close enough

*The **Rufous-browed Conebill** probes dense flowerheads and inflorescences with its thin, sharply pointed bill, but in search of insects rather than nectar. Conebills also inspect and probe clusters of leaves, and some specialize in foraging on leaves damaged by infestations of foliage-chewing insects. The Rufous-browed Conebill forages mostly in the tops of shrubs and smaller trees, including exotic vegetation in parks and gardens. It may also be found in the trees and bushes around small wetlands* (humedales) *on the high plateau savanna of the Sabana de Bogotá, occasionally moving out into the reeds and sedges.*

[*Conirostrum rufum*, Bogotá, Colombia. Photo: Pete Morris]

to peer up at the underside of leaves overhead. *Chlorochrysa* tanagers, which have unusually thick, strong tarsi, habitually work their way quickly out to branch tips and then hang upside-down from leaves or leaf clusters, from which they then inspect both surfaces of leaves. White-eared Conebills (*Conirostrum leucogenys*) also persistently inspect leaf surfaces in this manner, being especially attracted to the compound leaves of species of Fabaceae (Leguminosae/Mimosoideae), where they regularly remain high above ground and hang upside-down from leaf tips at the ends of large spreading branches.

3) **Leaf upper surfaces**. It has been noted that tanagers probably forage for arthropods on the upper surfaces of leaves proportionately more often than other bird species. In order to gain access to the tops of leaves, some tanagers have evolved specialized techniques. White-shouldered Tanagers often flutter in the outer foliage, peer downwards at large leaves, and then dart or leap downwards to attack prey; Guira, Rufous-throated and Speckled Tanagers, among others, stick the head up above the leaves and then execute acrobatic sallying manoeuvres to capture prey. Two high-Andean species, the Black-headed Hemispingus and the Drab Hemispingus, simply alight on large stiff leaves and stand or walk on the tops of them. In the lowlands, Palm Tanagers also sometimes walk on large leaves and, aided by their unusually sharp claws, regularly hang from the slippery tips of palm-frond leaflets to inspect the undersurfaces. In mountain forests White-winged Tanagers may sally out to snap arthropods from the tops of leaves, and in the lowlands Masked Crimson Tanagers employ a similar technique in sallying to the tops of leaves.

4) **Mossy trunks and branches**. In cloudforests of Central America and the Andes, where moss often covers almost all bark surfaces, many tanagers sprint along branches, pausing every second or two to inspect mossy surfaces or to probe for cryptic arthropods. Moss clumps also are checked by many highland genera, including *Bangsia*, *Buthraupis*, *Anisognathus*, *Iridosornis*, *Dubusia*, *Delothraupis* and *Chlorospingus*.

5) **Epiphytes**. Not only do many cloudforest tanagers inspect the surface or probe into clumps of moss, they also inspect the surfaces of a wide range of epiphytes, including bromeliads, ferns and orchids. Although information is scanty, a few species may partly confine their foraging to the surfaces of epiphytic plants, especially bromeliads. The Olive Tanager and the Ochre-breasted Tanager regularly rummage in bromeliads, as well as in arums and philodendrons (Araceae), two plants that often grow as epiphytes. Orange-bellied Euphonias pluck berries from the spike-like spadix of these plants and regularly glean small insects from inside the spathe; they also hover in front of spider webs suspended between philodendron leaves, and have been observed to pluck tiny spiders, as well as trapped insects, from these webs.

6) **Air: for flying insects**. Few tanagers are specialized morphologically for foraging on flying insects. The most prominent exception is the Swallow Tanager, which is often found in the tops of open trees and in semi-open areas; this species, with a broad gape and long wings, takes many flying insects in short sallies. Similarly, the Fawn-breasted Tanager, another species with long wings and a bill gape that is wider than that of most other tanagers, is often found in partly open areas and frequently sallies to air for insects. Inside tropical forests, shrike-tanagers, which have long wings for speed and a relatively long tail for manoeuvrability, are specialized for capturing insects in swift, aerobatic looping sallies. Red-legged Honeycreepers also capture many insects in flight and are far more insectivorous than other *Cyanerpes* honeycreepers, all of which have shorter bills; they make many captures in short sallies and aerial lunges in the vicinity of large canopy flowers, which attract insects. Although seemingly poorly adapted for capturing aerial insects, several species of *Tangara* regularly make short, awkward-looking sallies for flying insects. Despite the appearance of inefficiency or awkwardness when sallying, a few of these *Tangara* species, especially the Masked, Golden-hooded, Blue-necked and Golden-naped Tanagers (*Tangara ruficervix*), capture a significant number of flying insects. Many other tanagers occasionally seize aerial insects in flight and, while none seems well adapted for even short aerial sorties, they do, nevertheless, avail themselves of outbreaks of emerging termites (Isopoda) and other seasonal swarms of insects, and regularly pursue small flying insects. Rufous-throated Tanagers and both Black-and-yellow and Scarlet-and-white Tanagers regularly sally short distances or chase small flying insects.

7) **On or near the ground, in association with army-ant raids**. Arthropod prey flushed by army ants, especially those of the species *Echiton burchelli*, represent a food resource exploited by only a tiny fraction of tanagers. The best-known examples of

Heliconia (Heliconiaceae) flowers are bird-pollinated, relying in particular on hummingbirds (Trochilidae). But some thraupids, such as Diglossa *flowerpiercers, rob them of nectar by breaking in below the flower's sexual parts, while others, such as the* ***Scarlet-rumped Tanager*** *(left), eat the petals and other soft parts. Heliconias are plants of clearings, disturbed habitats and early secondary growth, habitats used both by many species of* Ramphocelus *and by the* ***Olive-backed Euphonia*** *(right).*

[Left: *Ramphocelus passerinii*,
Costa Rica.
Photo: Glenn Bartley.

Right: *Euphonia gouldi gouldi*,
Chan Chich Lodge,
Orange Walk, Belize.
Photo: Silvio Sommazzi]

On Caribbean islands and over much of its range in northern South America, the ***Bananaquit*** *occupies almost every type of habitat other than the deepest forest and the most arid scrub. It is common in gardens and parks, orchards, plantations, light woodlands and mangroves, and other places where flowers are abundant. It appears to be equally at home at any level, foraging from near the ground to the canopy. To a far greater extent than any other thraupids, including honeycreepers and flowerpiercers, Bananaquits are nectar specialists. They feed from a wide range of trees, shrubs, vines and herbaceous plants, restricted only by the length of their beak, which may prevent them from reaching into flowers with long corollas. However, they pierce the bases of some deep tubular flowers with their bill to get at the nectar. They feed in particular on dense clusters of small flowers which, probably because of the tiny amount of nectar that they contain, are not used by other thraupids. Bananaquits flit or hop quickly from one group of flowers to the next, and their head movements are very quick, enabling them to probe all the flowers in a cluster in a matter of seconds. In Trinidad, they compete only with the very smallest hummingbirds (Trochilidae) for these small flowers, although they exploit a far greater range of flowers than does any hummingbird species. Unlike hummingbirds, Bananaquits perch to feed and do not hover, and so expend less energy. They eat some small fruits and berries, but also pierce and suck the juice from larger fruits.*

[*Coereba flaveola chloropyga*, Juquiá, São Paulo, Brazil. Photo: Fabio Colombini]

Flowerpiercers (Diglossa) *have the most highly modified bill of all the thraupids. Both the upper and the lower mandibles are slightly upturned and there is a sharp hook at the tip of the upper mandible, while the lower mandible is short and sharply pointed. They feed by hooking the upper mandible over, or into, a flower corolla to hold it firm, while using the lower mandible to puncture the base of the corolla. The tongue is U-shaped in cross-section, and, when pressed against the lower mandible, forms a tube that aids the bird in rapidly extracting nectar; the tongue also has the brush tip typical of nectar-feeding birds. This bill shape is most pronounced in the smaller species in the genus, such as the* ***Slaty Flowerpiercer****, which obtains a substantial amount of its nourishment from nectar. The Slaty Flowerpiercer visits a wide variety of flowers, of both native and introduced species, and is especially fond of certain flowering shrubs and epiphytes. It forages with remarkable swiftness, each flower visit lasting little more than a second before the bird flits to another, nearby flower and repeats the process. Like other small* Diglossa *species, Slaty Flowerpiercers are extremely territorial, and pairs or non-breeding singletons will vigorously defend favourite flower patches against conspecifics. They may themselves be attacked and supplanted by larger species of hummingbird (Trochilidae).*

[*Diglossa plumbea*, Cerro de la Muerte, Costa Rica. Photo: Konrad Wothe]

There are documented instances of Diglossa *flowerpiercers extracting nectar by "legitimate" means, reaching into the flower, rather than piercing the base of the corolla and robbing it. A study of four species of flowerpiercer in the Colombian eastern Andes found that species with short bill and relatively large hook, such as the* ***White-sided Flowerpiercer****, were more likely to pierce and rob flowers than were those with a longer bill and small hook, such as the Masked Flowerpiercer* (D. cyanea)*, which were able to reach into longer corollas. Tubular, erect flowers were robbed most often; however, the flowerpiercers transported pollen between plants with pendent flowers and short to medium-length corollas.*

[*Diglossa albilatera albilatera*, El Dorado, Sierra Nevada de Santa Marta, Colombia. Photo: Ketil Knudsen]

army-ant followers among the Thraupidae are the Grey-headed Tanager, Red-crowned Ant-tanager and Red-throated Ant-tanager (*Habia fuscicauda*). While both Grey-headed Tanagers and Red-crowned Ant-tanagers regularly forage at army-ant swarms in Central America and northern South America, neither species is much associated with ant swarms in the Amazonian portion of its range. The Crested Ant-tanager follows swarms of the small black *Labidus* army ants in the Andean highlands of Colombia, but these swarms are infrequently encountered and unpredictable in occurrence and they do not provide a reliable resource base. The eastern, lowland population of the Black-goggled Tanager has been reported at army-ant swarms, but its discrete sister population in the Andes has not. Other tanagers, especially species of *Tachyphonus* and *Ramphocelus*, have occasionally been reported at swarms. In cooler highland forests army ants become increasingly scarce, and above about 1000 m these ants are rare. At this elevation and higher, the only army ant likely to be followed by birds is *Labidus praedator*, the swarms of which are typically rather small, unpredictable in occurrence, and not regularly followed by birds. Some species do take occasional advantage of these swarms, although none does so on a regular basis. Many birds, even canopy-level species that normally do not descend low, will opportunistically take prey items flushed by army ants. In western Colombia, between 980 m and 1250 m elevation, six *Labidus praedator* swarms were noted by Hilty, and at one large swarm an Emerald Tanager and ten Silver-throated Tanagers were present, some individuals descending as low as 0·3 m to capture fleeing prey; a few Silver-throated Tanagers appeared unsure of how to utilize this unusual resource or were intimidated by the presence of two species of ant-following antbird and were not observed to capture prey. Neither tanager normally forages so low, although both will descend briefly to about 3 m in order to feed on berries of fruiting shrubs. At another swarm, at an elevation of 1250 m, a pair of Moss-backed Tanagers was noted; both individuals foraged about 1–2 m up over this swarm, spending approximately12 minutes in capturing a few prey items before leaving. It is likely that many highland birds, including tanagers, make occasional use of prey flushed by army ants, but the importance of these ants to most highland birds is small.

8) **On the ground, in or near forest**. A few species of tanager regularly forage on the forest floor. Most notable are the Rosy Thrush-tanager and the two *Calyptophilus* species, the Eastern (*Calyptophilus frugivorus*) and Western Chat-tanagers (*Calyptophilus tertius*), all of which may ultimately prove to belong not with Thraupidae, but with other avian families (see Systematics). The thrush-tanager typically remains at one location on the ground for extended periods of time as it flicks leaves aside with its bill. More than 20 other tanagers, almost all of them lowland species, are known to forage occasionally on the ground. This group includes members of such varied genera as *Neothraupis*, *Tachyphonus*, *Eucometis*, *Trichothraupis*, *Habia* and *Ramphocelus*. No highland species currently classified as a tanager is known regularly to forage on the ground, although a few species of *Iridosornis* have been observed foraging on mossy rocks and roadside banks. On the other hand, many genera currently placed in Emberizidae, but now believed to be closer to tanagers (see Systematics), typically forage on the ground; they include the *Phrygilus* finches, the *Diuca* finches, the *Poospiza* finches, the *Embernagra* finches, the chaco finch genus *Saltatricula*, the two *Coryphospingus* finches, and also the single species of *Rhodospingus*.

9) **Arboreal dead leaves**. This substrate is an important foraging site for birds in several predominantly insectivorous families, such as the ovenbirds (Furnariidae) and the typical antbirds (Thamnophilidae). At least 25 species of tanager also regularly or occasionally inspect dead-leaf clusters for hidden arthropods. The Oleaginous Hemispingus is one of the most prominent searchers of dead-leaf clumps, and in many, or perhaps most, areas this species consistently searches dead leaves and hanging clumps of dead leaves. In the coastal cordillera of Venezuela, more than half of all prey captures made by this thraupid are from suspended dead leaves, although this species may take a higher proportion of prey in this manner here than it does elsewhere. In the Machu Picchu area of south-eastern Peru, the Oleaginous Hemispingus regularly checks dead hanging leaves, but it also frequently forages on mossy branches or other substrates. Several other species of hemispingus spend lesser amounts of time in searching clusters of suspended dead leaves. This foraging method is reported also for various species of *Thlypopsis*, *Tangara* and *Cnemoscopus*. Three other genera, namely *Habia*, *Chlorospingus* and *Chlorothraupis*, all now believed to be allied to cardinalids (see Systematics), also frequently search suspended dead leaves and clumps of old leaves lodged in branch forks.

*Small and agile species such as the **Chestnut-bellied Euphonia** are able to crawl over large inflorescences like this* Combretum fruticosum *flower, instead of hovering or perching alongside to peck at them. Clambering and thrusting their heads among the stamens as they probe for nectar and insects, they may do some damage to the flower. But they pick up pollen (clearly visible on the forehead of this bird), which they transfer to the plants which they visit subsequently. Chestnut-bellied Euphonias also take sugar water from hummingbird feeders.*

[*Euphonia pectoralis*, Ubatuba, São Paulo, Brazil. Photo: Ivan Sazima]

10) **Damaged leaves**. This is a substrate utilized to varying degrees by some species of dacnis, which, in general, take more insects than fruit. Damaged leaves can provide a particularly rich insect foraging site. When foliage-chewing insects are active and the damage is extensive, hundreds to thousands of holes in clumps of leaves are evident and may blight entire trees. Foraging Blue Dacnises have been observed to fly directly from one damaged leaf site to another. Pearly-breasted Conebills (*Conirostrum margaritae*), which occur mainly in stands of young *Cecropia* on newly formed river islands in Amazonia, also make extensive use of damaged leaves. Chestnut-vented Conebills (*Conirostrum speciosum*), at least locally, and Bicolored Conebills in the Amazon region, but not coastally, along with a few *Tangara* tanagers, such as the Golden-naped Tanager in Colombia, also make use of damaged leaves as food-resource patches.

11) **Bamboo**. Although bamboo is an important and sometimes exclusive micro-habitat for birds across the southern Amazonian lowlands, and also an important foraging site for a wide range of species near the tree-line in the Andean highlands, relatively few tanagers use it to the exclusion of other substrates. The single known exception to this is the Plushcap (*Catamblyrhynchus diadema*), which systematically searches the leafy internodes and, to a lesser extent, the stems of *Chusquea* bamboo in the highlands. Bamboo is an important foraging substrate also for the Rufous-browed Hemispingus in Bolivia and somewhat less so for several other hemispingus species. Other highland tanagers, including *Chlorornis*, *Dubusia* and several species of *Iridosornis*, are often closely associated with bamboo when foraging, although they seem not to be dependent upon it.

12) **Flowers**. While flowers are usually regarded in the context of nectar resources, some, especially mass flowerings in forest canopy trees, attract many insects, and a few species of tanager regularly use flowers as insect-holding substrates, picking insects directly from flowers and sallying short distances in the vicinity of the flowers. Both Green Honeycreepers and Red-legged Honeycreepers take many insects in short fluttering sallies near flowers, and the Golden-collared Honeycreeper, a scarce species for which little information is available, has also been observed while fluttering and sallying for insects around flowers. Several *Tangara* tanagers, including the Blue-necked, Masked, Golden-hooded, Rufous-throated and Grey-and-gold Tanagers, may employ this technique for obtaining insects; indeed, many, if not most, members of the genus *Tangara* opportunistically forage in this manner.

When the taxonomy affecting the thraupid family settles down once more, the revisions are likely to include species with foraging-substrate specializations that fall well outside those listed above. While it is unlikely that any of the above categories will be eliminated from the list by pending taxonomic changes, except possibly that involving the following of army ants, a few prominent foraging substrates not included in the list are worthy of brief mention, because they are utilized by species likely to be transferred from Emberizidae to Thraupidae in the future. Among them are (i) grass stems, which are utilized by all *Sporophila* and *Tiaris* species as perch sites which the birds ride downwards, causing the stems to bend over so that the birds can then reach out and down along the stems to obtain seeds and, perhaps, occasionally insects; (ii) open bare or rocky ground, substrates used by many *Phrygilus*, *Diuca* and *Sicalis* finches of the high Andes and Patagonia; and (iii) the ground in tall grassland, a substrate exploited by *Embernagra* and species in a few other emberizid genera.

In a summary of arthropod prey items taken by tanagers, the Isler team found that 62 species included larvae and caterpillars in the diet, 57 included beetles (Coleoptera), 39 incorporated wasps and bees (Hymenoptera), and 34 species took orthopterans. Although the survey was incomplete and probably biased towards the captures of large insects, which are more visible to field observers, the sample does show that tanagers take a broad range of arthropod prey. It also suggested that highland tanagers took more beetles and grub-like insects than their lowland counterparts. Lowland tanagers, in general, took a wider variety of arthropod prey items than highland species, doubtless a reflection of greater lowland-insect diversity, and greater orthopteran diversity in particular in the lowlands.

Small tanagers of less than about 15 cm are more likely to specialize on specific substrates when foraging than are larger tanagers. Many small tanagers move along branches and twigs or through foliage and search for prey in a methodical but often highly stereotyped manner, myopically inspecting their preferred substrates from as close as 2–5 cm. *Tangara* tanagers are often cited as extreme examples of this substrate specialization. In a

Mostly insectivorous, the ***Western Tanager*** *forages in the upper levels of coniferous trees and the canopy of mature alder trees (*Alnus*). It examines the foliage, hopping or jumping from perch to perch and taking prey mostly by pecking from leaves. It sometimes remains motionless except for head movements as it watches for flying prey, and sallies varying distances into the air for flying ants and termites. Hymenopterans, mostly wasps but some ants, account for 56% of its insect food, increasing to 75% in August. In Montana, the Western Tanager was observed to hover over musk thistle* (Carduus nutans) *heads and attempt to pick out the introduced weevil* Rhinocyllus conicus.

[*Piranga ludoviciana*, Victoria, British Columbia, Canada. Photo: Glenn Bartley]

summary compilation of foraging behaviour from various sources for 31 species of *Tangara*, the Islers found that at least 24 species, 77% of the total, were substrate specialists, preferring to forage in specific ways and on specific substrates to the virtual exclusion of other sites. In their sample, 15 species searched for arthropod prey mainly on branches, five from leaves and one from the undersides of leaves and branches, and three often captured insects in short aerial sorties. Even more remarkably, those species which preferred branches, almost half of the total, could be further divided into several subcategories, including those that habitually inspected bare branches and those that favoured mossy or partly mossy branches. More recent studies, detailed below, have shown that substrate discrimination in *Tangara* communities can be even finer. Such extreme specialization with regard to the invertebrate portion of the diet is most obvious in the Andes, where up to ten species of *Tangara* may have overlapping or partially overlapping ranges and are, in turn, replaced by others at successively higher elevations. Foraging specialization is characteristic of lowland *Tangara*, as well, and it is not uncommon to find up to eight overlapping species locally in Amazonia. There

Although active and full of nervous energy, the ***Chestnut-vented Conebill*** *is easily overlooked as it forages high in the outer foliage of spreading branches. It is especially fond of searching the tiny leaflets and axils of the compound foliage of legumes (Leguminosae), busily hustling from one spray of leaflets to the next, often hanging upside-down to probe and glean. It may exploit damaged leaves for foliage-chewing insects. Pearly-breasted Conebills* (Conirostrum margaritae)*, which occur mainly in stands of young* Cecropia *on newly formed river islands in Amazonia, make more extensive use of damaged leaves as a foraging substrate.*

[*Conirostrum speciosum speciosum*, Cachoeiras de Macacu, Rio de Janeiro, Brazil. Photo: Narciso Cipriani]

Chlorothraupis *species forage mostly in the understorey. The* ***Olive Tanager*** *seems more restless and faster-moving than others in its genus, as it hops along branches or flies short distances to new perches. It is generally seen in smaller parties than Carmiol's Tanager* (C. carmioli)*, with which it was once thought to be conspecific. Carmiol's Tanager searches for larger insect prey such as beetles (Coleoptera) and crickets (Orthoptera) by hopping, rummaging and peering, lunging forwards or hanging downwards. Of observations of Carmiol's Tanagers feeding on insects from leaves, 65% involved the leaf undersides.*

[*Chlorothraupis frenata*, Amazonia Lodge, Manu Biosphere Reserve, Madre de Dios, Peru. Photo: Roland Seitre]

are, however, far fewer species overall in the lowlands compared with the highlands, and foraging substrate specialization may be less extreme.

In western Ecuador, Naoki examined the patterns of foraging, for both arthropods and fruit, in a community of seven sympatric species of *Tangara*. To achieve her objective, she took foraging data over a period of seven months in order to permit a detailed analysis of foraging parameters, and to test whether foraging differences among the species resulted in resource-partitioning. Naoki's analysis showed that not only did substrate preference differ among the seven tanager species, as was found in the broad analysis by the Islers, but the physical attack manoeuvres used to obtain arthropods also differed, as did the horizontal foraging position within trees and the preferred habitat. An example of the fine discrimination displayed by these small mixed-diet species can be seen in the attack manoeuvres and foraging substrates of the Golden Tanager and the Flame-faced Tanager, two forest-dwelling species both of which used inner and middle portions of thick branches and searched in a highly stereotyped manner by reaching down or hanging downwards to check first one side of a branch, then the opposite side, all the while progressing outwards a few hops at a time. Beryl-spangled Tanagers employed similar stereotyped searching movements, but searched only thin branches and twigs in foliage. Metallic-green and Rufous-throated Tanagers searched mainly in outer foliage, inspecting and gleaning from the tops of leaves, or reaching up from below to the undersurfaces. Blue-necked and Golden-naped Tanagers differed still further in often sallying or fluttering short distances to the air. The species which were most similar to each other in foraging behaviour, such as the Golden and Flame-faced Tanagers, differed in both foraging position and attack manoeuvres: the Flame-faced foraged mostly on mossy branches and often probed into the moss; whereas the Golden Tanager foraged far less on mossy branches and, when it did so, picked prey items from the surface, rather than obtaining them by probing. Metallic-green and Rufous-throated Tanagers both used leaf substrates for foraging, but the latter employed more manoeuvres involving hanging upside-down, especially to get at leaf undersurfaces and when searching large leaves. Further, the two species differed somewhat in habitat preference and the elevation at which they occurred, with Metallic-green more in forest and at higher elevation and Rufous-throated more in edge and disturbed situations at slightly lower elevations. A final example is provided by the Blue-necked and Golden-naped Tanagers, which obtained a majority of their prey in short aerial sallies, but favoured different habitats. Approximately 80% of the recorded foraging attempts of Blue-necked Tanagers were in semi-open habitat and a further 15% were in secondary forest, while for Golden-naped Tanagers the situation was almost exactly the reverse.

In contrast to the tanagers' foraging behaviour when seeking arthropods, Naoki found few differences in the methods by which

One or more Chlorospingus *bush-tanagers can be found in almost all humid montane forests from Mexico south to Bolivia. They hop quickly up slanting branches and twigs until they are close enough to peer up at the underside of leaves. They also check moss clumps, and frequently search bunches of dead leaves. The* ***Dusky Bush-tanager****, seen here with a moth (Lepidoptera), is particularly attracted to vine tangles, which it searches from near the ground to the treetops. It is seen high or in the canopy more often than are other* Chlorospingus.

[*Chlorospingus semifuscus paulus*, Sachatamia, Mindo, Ecuador. Photo: Tom Friedel/VIREO]

the species of *Tangara* obtained the fruit portion of their diet. Golden and Flame-faced Tanagers perched on the thick hanging catkins of *Cecropia* more than did other species, and thus used vertical perch positions. In comparison with other species, Rufous-throated Tanagers ate more berries of *Trema*, an early-successional-stage tree in regrowth areas, and thus had a higher average perch height. Otherwise there were few interspecific differences in foliage density, or in preference for vertical or horizontal position of perches utilized when feeding on fruit. More than half of all records of fruit-eating involved simple reaching and gleaning manoeuvres, and the berries of two species of *Miconia* accounted for almost half of all fruit consumed by the seven species of *Tangara*.

In summary, Naoki found that when *Tangara* foraged for arthropods, the various species in a community each searched slightly different substrates, no species overlapping completely with another conspecific. Naoki also found that, secondarily, they also differentiated slightly in the habitats they occupied. These differences result in a low degree of resource overlap and a particularly low overlap among species occupying the same habitat and foraging in the same mixed-species flock with other *Tangara*. On the other hand, when searching for fruit, most species of *Tangara* ate the same kinds of fruit, and overlapped widely with congeners using the same habitats. These results suggest that it is the arthropod portion of the diet, rather than fruit, that is the more important factor reducing competition for food.

While Naoki's study is the most detailed published work to date on resource-partitioning by tanagers, some unpublished findings by Hilty in Colombia suggest a closely similar pattern. The high species diversity in these *Tangara* communities appears to be maintained not by fruit abundance, because there is relatively little competition for it, but by the ability of these species to partition their foraging sites to a remarkably high degree through differences in a combination of foraging manoeuvres, substrate use, foraging position and habitat. Such fine-grained micro-habitat and behavioural discrimination presumably means that the species are feeding on different subsets of arthropods, and in this way avoid direct competition for the higher-quality portion of their diet.

Whereas small-bodied tanagers tend to be substrate specialists, the larger species are, conversely, more likely to be substrate generalists that search for prey by peering at sites beyond their immediate reach. As a consequence, their movements are less stereotyped, involve more generalized searching, and usually entail a brief lunging attack to capture prey. Mountain-tanagers of the genera *Anisognathus* and *Buthraupis* employ this type of searching behaviour, which involves hopping along a branch and peering in a deliberate manner at branches and foliage, and then reaching out or lunging to grab prey once it is located. In the highlands, species in several genera, including *Iridosornis*, *Creurgops*, *Bangsia* and *Dubusia*, employ somewhat similar for-

Apart from some seasonal fruit, the ***Summer Tanager*** *eats mostly arthropods. It sallies after flying insects like the one seen here. Its diet includes many bees and wasps (Hymenoptera), and wasp larvae. When attacking the nests of the wasp* Polistes exclamans, *the bird hovers by the nest, catching flying adults in its beak. When all the adult wasps are eaten or have escaped, the Summer Tanager attacks the nest with its beak and eats the larvae inside. By the end of the bird's visit, the nest is shredded and the colony destroyed.*

[*Piranga rubra rubra*, Costa Rica. Photo: Glenn Bartley]

Hemispingus *tanagers were sometimes considered to belong with New World warblers (Parulidae), and the* ***Black-capped Hemispingus*** *behaves very much like one when it is foraging. It often acts as the leader of fast-moving mixed flocks, which include* Basileuterus *warblers and other small tanagers. It gleans or picks insects and other small arthropods from foliage, mainly from near the ground to around 6 m up. It also forages in bamboo, but does not specialize on it. Its congener the Rufous-browed Hemispingus (H. rufosuperciliaris) is one of the few tanagers that uses bamboo extensively.*

[*Hemispingus atropileus*, Río Blanco Reserve, Manizales, Caldas, Colombia. Photo: Ketil Knudsen]

aging tactics. In a common variation, *Tachyphonus* tanagers move faster and, once they locate a prey item, attack with lunging motions and quick darting actions that may end in an acrobatic chase. *Thraupis* tanagers, including such common and widespread species as the Blue-grey and Palm Tanagers, incorporate any or all of these movements, sometimes moving rapidly, at other times more slowly, and also often fluttering to foliage or branches in pursuit of escaping prey. Other large-bodied lowland tanagers, including *Schistochlamys*, *Neothraupis*, *Lamprospiza*, *Ramphocelus* and *Stephanophorus*, all employ various methods of hopping rather heavily along limbs or in thicker shrubbery and peering around, before lunging after prey. *Eucometis*, the Grey-headed Tanager, behaves in a similar manner, but, in an unusual variation, it regularly forages in the vicinity of army ants. Waiting at the periphery of raiding swarms, it lunges or goes to the ground repeatedly to capture arthropod prey attempting to escape from the ants. Some species of *Habia* ant-tanager, a group now thought not to be closely related to tanagers (see Systematics), also follow raiding army ants, at least in the northern portions of their range, but their movements of peering and then lunging recall those of other larger-bodied tanagers.

Shrike-tanagers, the genus *Lanio*, are another group of relatively large-bodied tanagers that are not substrate specialists. Widespread in humid lowland forests, they follow mixed-species flocks and forage by engaging in fast aerial sorties within the confines of the subcanopy or canopy, where they regularly chase flying prey flushed by other species. In south-eastern Peru, the foraging behaviour and social role of the White-winged Shrike-tanager within mixed flocks have proved to be of considerable interest. Notable for its often loud, sharp alarm calls, the species is reported as behaving both as a sentinel to the flocks by warning of danger and, occasionally, as a thief by issuing false warnings to distract a competitor if the outcome of an aerial pursuit of prey is in doubt. Because shrike-tanagers keep a lookout for prey by sitting on relatively open branches beneath the canopy, they usually have a more unobstructed view of their surroundings than other species. As a result of their alertness, they are quick to spot prey items flushed by other species and, more often than not, they are the first to capture these escaping prey items. They also are among the first to detect predators, such as incoming hawks. Verified instances of false alarms, or "lying", in avian ecosystems are rare, and the shrike-tanager's behaviour appears to be unique within the social structure of mixed-species flocks. Munn, who was the first to confirm this behaviour among shrike-tanagers, was able to show that false alarms, or "crying wolf", by these birds were given with somewhat greater frequency when pairs were feeding young, but even then they remained infrequent.

Birds that eat fruit are found in a wide range of both tropical and temperate-latitude families, although very few of them, either as adults or as nestlings, live on fruit alone. In most cases, as is true with the tanagers, adults consume fruit and supplement it with protein-rich arthropod prey, mostly insects. Nestlings, because of their greater need for protein for growth, are initially fed almost entirely with insects. Fruit, however, is often readily available and easy to harvest, and it is an important food for tanagers. As noted previously, fruit comprises half or more of the food items eaten by approximately 68% of all tanagers. In fact, all members of the family Thraupidae, as currently constituted, include at least some fruit in the diet. Forthcoming taxonomic changes within the family (see Systematics) will modify these generalizations, with the likely inclusion of several genera that are primarily seed-eating species, such as *Phrygilus*, *Sporophila*, *Tiaris*, *Geospiza* and others, and the eventual exclusion of several frugivorous groups currently included, such as *Euphonia*, *Chlorophonia* and *Chlorospingus*.

All tanagers are relatively small birds, and the range of fruit and seed sizes which they can handle and process is largely limited to small items or, in a few instances, to large fruits from which they can remove pieces of pulp, by pecking at the item, and leave the seeds intact. As a food resource, fruit presents a number of difficulties for birds, because it is usually low in protein compared with caloric value, it is mostly water, and it contains seeds which are heavy and indigestible. Indeed, seeds can add as much as 50% in indigestible bulk to a fruit item. Among bird-dispersed seeds, the fruit pulp surrounding the seeds is typically either rich in lipids (fats) and often large, or high in carbohydrates (sugars) and small in size. Rarely are fruits high in both lipids and carbohydrates, containing more than 20% of each. Surveys of a variety of tropical plant families with bird-dispersed fruits show a median protein level of 8·4% by dry weight. This compares with a median of 12% for cereal seeds and one of 66% for a sample of 19 species of insect.

Around 20 species of lowland tanager, including some Habia *ant-tanagers, occasionally forage on the forest floor. Of 4000 foraging attempts by the* ***Red-throated Ant-tanager*** *in Belize, 75% were below 5 m, and the species often foraged on the ground around army-ant (Formicidae) swarms. While capturing prey flushed by army ants, the Red-throated Ant-tanager may hop on the ground briefly to grab prey or use horizontal perches. It hops along branches, peering rapidly, and frequently turning about-face before lunging for escaping insects. Its behaviour is similar away from ant swarms, where it perches mostly in a horizontal position and reaches or pecks prey from foliage and trunks.*

[*Habia fuscicauda salvini*, Belize.
Photo: Christian Artuso]

Euphonias have been maintained in captivity on diets consisting largely of bananas, and the ***Spot-crowned Euphonia*** *is known to visit feeders to eat pieces of this fruit. An experiment at La Selva Biological Station, in Costa Rica, used a banana diet to examine the sugar-tasting abilities of tanagers and manakins (Pipridae). The tanagers were of four genera:* Euphonia, Ramphocelus, Thraupis *and* Tachyphonus. *The first three were able to detect differences of 2% in the sugar content of the banana mash, and all three preferred the sweeter mixtures. Only the Tawny-crested Tanager* (Tachyphonus delatrii) *was, like the two manakin species, indifferent to the sweetness.*

[*Euphonia imitans*, Osa Peninsula, Costa Rica. Photo: Felipe López]

Most tanagers and other small fruit-eating birds are limited to eating small fruits which are generally little more than juicy packets of sugar. On the other hand, large fruits are more likely to have higher protein and fat contents, and large specialized frugivores such as cotingas, toucans (Ramphastidae) and the Oilbird (*Steatornis caripensis*), because of their size, are able to harvest a much wider range of fruit. Tanagers exhibit few special morphological features specifically for handling fruit. For example, the Swallow Tanager is the only thraupid with a bill and gape wide enough to enable it to eat even what are moderate-sized fruits in relation to its body size, and *Euphonia* and *Chlorophonia*, genera now generally placed with the Fringillidae, are the only ones with a digestive tract modified for quick passage and gentle handling of fruit pulp and seeds. As most tanagers consume both fruit and insects, their digestive tracts do not differ appreciably from those of insectivores. For example, small frugivores have a thin-walled, non-muscular gizzard and a small crop similar to those of primarily insectivorous birds, and the passage rate of food material through their gut is, likewise, similar to those of the latter. Although it has been suggested that frugivores should have a shorter gut to facilitate quick passage of heavy ballast pulp, and a large liver to aid in detoxification of the secondary compounds often present in fruit, researchers have found no constant patterns in these or other internal morphological adaptations. Generally, small birds do not possess any morphological adaptations for storage of fruit, as the crop is either small or lacking, and the proventriculus and oesophagus are also small; the proventriculus is enlarged in *Euphonia* and the oesophagus is extensible in the Swallow Tanager, but these apparently represent exceptions. Among small fruit-eating birds such as tanagers, adaptations to accommodate fruit in the diet are in general likely to involve behavioural changes, rather than slowly evolving and less flexible structural morphological changes. Not surprisingly, small birds that feed mostly on insects are capable of eating fruit about as readily as those feeding on fruits can eat insects. Differences in the abilities of the two groups to utilize fruit are more likely to be related to the external morphology, mainly leg length and wing shape, which can affect harvest time, rather than to specific internal anatomical features that aid digestion once the fruit is harvested. In both cases, the ability to switch diet, or to shift the proportions of food types in the diet, is advantageous during periods when a major resource is limited. While tanagers exemplify a dual fruit–insect dietary strategy, many other small frugivores pursue a mixed diet with varying proportions, including species of the families Tyrannidae, Pipridae, Cotingidae, Cardinalidae and Emberizidae, among others, in the New World.

With their small size, tanagers generally process fruit either by plucking a fruit and swallowing it whole or, if the fruit is larger, by mashing it and eating it piecemeal. Mashing a fruit, often referred to as mandibulation, is a type of behaviour that is, so far as is known, unique to nine-primaried oscines. Typically, small seeds are swallowed whole, whereas large seeds are often mandibulated for a few moments in order for the seed to be extracted and dropped. The mashing of fruits may also serve to squeeze out watery juice, which is heavy and has less food value when compared with pulp.

Even with their limitations of small size and relatively unspecialized physical anatomy, tanagers take an enormous range of small fruits. Most tanagers have a bill that is not exceptionally wide or flat and is moderate in length. Birds that take fruit while on the wing usually have a wide, flat bill that is also short, whereas those that take fruit while perched usually have a longer and more narrow bill. These differences can affect which fruits are accessible to a bird. For example, birds that take fruit when in flight usually have shorter or more rounded wings and are adept at hovering or swooping up or snatching to grab the fruit. Birds that obtain fruit by reaching in various ways, such as most tanagers, are constrained by leg-muscle mass, and strength and size of the tarsus, in the ways in which they are capable of reaching.

Few bird species are able efficiently to reach for fruit items and also to hover and pluck them while on the wing. In this regard, *Euphonia* and *Chlorophonia* represent a compromise. Species in both genera hover, but are less efficient at hovering than manakins, and their bills, although not exceptionally wide or flat, are short and rather thick, which may prevent them from reaching as far or as efficiently as many species, thereby limiting the range of fruits that they can efficiently harvest. These compromises, however, may be offset by their more highly modified gut anatomy, which permits them to harvest certain potentially toxic resources such as mistletoe berries. Mistletoe-berry pulp is harmless, and one species has been shown to be high in lipids, but the seeds are highly toxic. Mistletoe seeds are coated with a slippery

Tanagers obtain a good proportion of their water requirements from their diets. For nectar-eaters, excess water from very dilute nectar may even be a burden, which prevents them from meeting their energy requirements from what they are able to consume. When tanagers drink, they can do so by suction, without needing to tip the head to swallow each beakful of water. Drinking is an activity that makes them vulnerable; predators may lurk near regular watering places, and during the time its head is down and its beak immersed, the bird is unable to be vigilant. The ***Summer Tanager*** *(above) drinks by dipping its beak for a split second, then raising its head to look around before dipping its beak again. The* ***Swallow Tanager*** *(below) will come down to the ground to drink at pools and streams, but will also take advantage of elevated water sources such as spouts and gutters, and puddles on flat roofs. It has been suggested that suction-drinking by tanagers derived from the already extant behaviour of mandibulating succulent fruit.*

Male tanagers display to females by showing off their brightest or most contrasting feathers, such as the bright blue back of the ***Blue-naped Chlorophonia****. The few courtship displays described for tanagers include bowing and tail-lifting. In the two genera studied in detail,* Ramphocelus *and* Chlorospingus*, displays including sexual behaviour were found to be partly or wholly similar (although* Chlorospingus *now appears to be closer to parulid warblers than to tanagers). Chlorophonias and euphonias are also now thought to belong in another family (Fringillidae); they differ from all thraupids except the Bananaquit* (Coereba flaveola) *in building covered nests.*

[*Chlorophonia cyanea cyanea*, Itatiaia City, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

covering that, if disturbed, exposes the potentially toxic seed to the gut, and this could result in the poisoning and death of a small bird if the seeds were digested or remained long in the alimentary tract. Consequently, mistletoe berries, as a fruit resource, are generally avoided by many groups of birds. In the Neotropics, chlorophonias, euphonias and a few small, specialized tyrannids are the principal consumers of mistletoe berries; in addition to having gut modifications, all three groups void the sticky seeds in long strings. The birds wipe the seeds, which stick together like strings of tiny pearls, off their rear parts and across branches by using a curious to-and-fro motion, as if the bird were swivelling its hips. This behaviour accomplishes two purposes: it assures that the bird is rid of the unwanted seeds and, coincidentally, that the seeds are deposited on a bare branch, where germination is possible.

While many of the fruits eaten by tanagers are rather unremarkable in size and shape and in colour, two other types, in addition to mistletoe berries, are worthy of mention. These are *Cecropia* catkins and arillate fruits, and both are widely taken by many tanagers. *Cecropia* is a conspicuous genus of trees in the family Urticaceae, with more than 100 species in the New World. The family is distinctive for its large, radically lobed, peltate leaves, which impart an open shape to the sometimes branchless trees. *Cecropia* species also have hollow internodes inhabited by ants, glycogen-containing food bodies at the base of the petioles, and distinctive fruits, which are finger-shaped catkins that project upwards or downwards in clusters. Many species of *Cecropia* are pioneer trees that thrive in regrowth and successional areas, although a few are canopy members of mature forest, especially at middle elevations in the Andes. *Cecropia* trees rely principally on birds, as well as some mammals, for the rapid and widespread dispersal of their tiny seeds, which are densely packed in the catkins. Many species of tanager include *Cecropia* catkins in their diet, either throughout the year or seasonally. Tanagers may perch on the stem containing the catkins and reach out or down to the catkin itself, or they perch directly on a catkin, sometimes clinging to the side of it, as they reach down to peck away pieces of the fruit material, swallowing the food on the spot. The importance of *Cecropia* in the year-round diet of a thraupid community in western Colombia is evident in the unpublished data of Hilty. In a community of 41 species of tanager, 17 species were recorded as feeding in every month on the catkins of a group of *Cecropia reticulata* trees, which were monitored on five mornings each month. Usage peaked in October, when 25 tanager species were recording as feeding at these trees. The catkins were such an important food resource that this single species of *Cecropia* was responsible for, each month, from 5·3% to 13·8% of all fruit-foraging records within the tanager community. Although production of *Cecropia* catkins and the use of these as food by bird communities are seasonal in areas with well-marked wet and dry seasons, these results underscore the importance of this genus, indeed the importance of a single species of *Cecropia* tree, in a tropical bird community.

Arils are often brightly coloured red or orange, fleshy pulp-like coverings that encapsulate some seeds. They are usually produced inside tough, even woody pods or multi-pointed, star-shaped fruiting structures that eventually split open to reveal layers of bright arils. One species of arillate fruit that was tested in Costa Rica was rich in both proteins and lipids, and it is not surprising, therefore, that arillate fruits attract a wide range of small frugivorous birds, including honeycreepers, dacnises and many *Tangara*. One of the commonest aril-producers is *Clusia*, a sclerophyllous-leaved tree or shrub of the family Clusiaceae that usually grows as an epiphyte or hemi-epiphyte or climber, and produces large resinous, capsular fruits that split open like multi-pointed stars to present rows of bright red-orange arillate seeds. Most arils are eaten by birds even before the fruiting capsule is fully open, and honeycreepers, especially those in the genera *Cyanerpes* and *Chlorophanes*, aided by their long bill, are among the first to be able to reach the arils sequestered inside.

Miconia and several related genera in the family Melastomataceae represent, collectively, one of the most important fruit resources for small birds in the Neotropics, and especially for *Tangara* tanagers. The small, juicy berries of *Miconia* are presented in flattish panicles at the end of branches of mostly small trees and shrubs, and are eaten by many kinds of bird. Melastomes, in fact, quickly colonize small openings in humid lowland and montane forest, especially in treefalls, at landslides, along streams or wherever in the forest there is an open area. They are especially numerous on steep mountain slopes, where a high level of rainfall creates abundant, year-round opportunities for colonization. One to a half-dozen or more species of these

Courtship feeding, performed here by the ***Azure-shouldered Tanager****, has previously been recorded for another* Thraupis *species, the Blue-grey Tanager* (T. episcopus), *as well as for* Tangara *and* Chlorophanes *species. In courtship feeding the male usually feeds the female, although instances of female tanagers feeding their mates have been recorded. Courtship feeding has also been observed for* Piranga, Chlorophonia *and* Euphonia, *genera included in Thraupidae but now thought to belong elsewhere.*

[*Thraupis cyanoptera*, Intervales State Park, Ribeirão Grande, São Paulo, Brazil. Photo: Greg & Yvonne Dean/ WorldWildlifeImages.com]

shrubs or small trees can usually be found fruiting in almost any month of the year. The berries consist mostly of carbohydrate. They are abundant and easy to harvest, and are taken by birds ranging in size from manakins and small tanagers up to pigeons (Columbidae), toucans, and guans (Cracidae). As they are produced in such copious amounts, a strategy that insures that their tiny seeds are widely distributed, they are among the first woody plants to colonize an opening in the forest. On steep Andean slopes, various species of *Miconia* and a few related genera of these widespread and common plants may comprise a significant proportion of all fruit eaten by *Tangara* tanagers. In an unpublished study undertaken by Hilty on the Pacific slope in Colombia, consumption of the berries of 19 species of *Miconia* by 23 resident tanager species varied from representing 13·9% of all records of fruit-eating in February to a high of 64·4% in December. In Naoki's study of seven *Tangara* tanagers, *Miconia* accounted for 33–78% of all the observations of fruit-foraging by the seven tanagers. Nearly half or more of all fruit consumed was from one plant alone, *Miconia brevitheca*, and this species together with *Miconia micrantha* accounted for nearly two-thirds or more of all fruit-foraging observations. Such remarkably high dependence on only two species of plant is a clear indication of the importance of *Miconia* in the diets of these tanagers, and suggests the likelihood of a co-dependent link between seed-producers, in the form of *Miconia*, and seed-dispersers, represented by tanagers and other birds.

Most species of tanager forage in some type of mixed-species flock, but the extent to which they participate varies from one species to another, and it is difficult to formulate generalizations regarding the diets of tanagers and their tendency to travel with flocks. Furthermore, the flocks, themselves, can be composed of dramatically different species having different agendas, depending upon the foraging choices of the species in the flocks. For example, in lowland rainforests, mixed flocks tend to be composed primarily of insectivorous species, one flock type foraging mainly higher up in the rainforest, and another in the understorey. Although the two flock types occasionally overlap, or even merge, the species in one flock type are largely different from those in the other type, and the flocks themselves, although they seem to coalesce around one or a few vocal species, are almost always composed of two to six permanently associated species that forage together, each species defending a common territory that more or less coincides with the territory used by the flock. In a study of colour-ringed birds in south-eastern Peru, Munn and Terborgh discovered that canopy flocks typically consisted of six core species, of which three were tanagers; in the understorey, flocks were also composed of six core species, all different from the canopy flocks, and none was a tanager. They also observed 20 additional species of tanager participating in one or both of these two types of flock, but in both examples tanagers comprised a minority of the species in the flocks. In Panama, J. A. Gradwohl and R. S. Greenberg observed similar behaviour in mixed-species flocks, although the total number of core species, as well as species joining the flocks, was smaller.

It is worth noting that a third flock type, not studied by investigators in Peru or in Panama, appears to roam primarily canopy tops and emergent trees in tall rainforest, and represents yet a third type of social structure. These emergent-tree flocks are composed primarily of tanagers, dacnises and honeycreepers, and they may be transitory, perhaps seasonal, and are variable in composition. Participating members band together early in the morning, range widely through emergent or high canopy trees, may visit fruit resources, and typically do not remain together for extended periods of time. Some individuals disperse and may join the primarily insectivorous, canopy-dwelling mixed-species group foraging below. The erratic appearance of these fast-moving emergent-tree flocks suggests that they re-form and disperse repeatedly during the day. These transitory flocks of tanagers, dacnises and honeycreepers have not been the focus of study. Qualitative observations suggest, however, that species in them are mostly small, with a mixed diet of fruit and arthropods, that they also join larger permanent flocks for varying periods of time when actively insect-seeking, but that they frequently leave these flocks to search for fruiting trees or to rest and loaf between foraging bouts.

In the highlands of Central and South America, flock composition is equally varied and the social roles of species in the flocks may vary geographically. In a study in cloudforest in central Costa Rica, mixed flocks of mostly insect-eating birds formed around a single core species, the Common Bush-tanager, and other attendant species joined or left as the bush-tanager foraged through its home range. In another study in Costa Rica, however, bush-

*The nest of the **Swallow Tanager** is built by the female from various fibrous materials. The Swallow Tanager is a hole-nesting species, often using existing holes in cliffs and banks, trees and walls, though capable of digging its own hole in soft earth. The eggs are completely white or only lightly marked, which is typical of hole-nesters. Pair formation by this species includes extended bowing, sometimes accompanied by "bouncy hopping" and chasing. Breeding males also bow extensively to each other.*

[*Tersina viridis viridis*, Lindóia, São Paulo, Brazil. Photo: Geiser Trivelato]

tanagers behaved as attendant species. In the Andes, flock structures are also varied, and range from small groups of primarily insectivorous species that forage in the understorey to fast-moving tanager-dominated flocks that feed heavily on small fruits and share a more or less common home range. This situation is similar to that of the flocks studied by Munn and Terborgh in the lowlands. These highland flocks, however, differ from the lowland ones in their much greater speed of travel, often covering hundreds of metres in a few minutes as they sweep across steep ravines or leap-frog along misty slopes. They differ further in being dominated by small, fast-moving tanagers, members of the genera *Tangara* and *Chlorochrysa* at middle elevations, and other genera, mainly *Buthraupis*, *Chlorornis*, *Anisognathus* and *Delothraupis*, at higher elevations. The daily activity patterns of these flocks, unlike in the lowlands, appear to be strongly influenced by prevailing weather patterns, with foraging activity conspicuous and accelerating to a frenzy ahead of oncoming rainstorms. On the other hand, on hot sunny days in the Andes, foraging activity becomes remarkably inconspicuous and quiet, and, if it continues at all, it is mainly in the shady forest interior and out of view.

Tanagers that occur in semi-open areas are least likely to join or participate in mixed-species flocks, perhaps largely because few mixed flocks form in these habitats. Not all tanagers in forested habitats, however, join mixed-species flocks. A few species, the Dusky-faced Tanager (*Mitrospingus cassinii*) being one example, are noisy and troop about in the understorey in groups of their own. The Ochre-breasted Tanager, another understorey species now believed unrelated to tanagers, forages in mixed flocks or in large, single-species flocks in about equal measure. The Swallow Tanager, perhaps because of its habit of perching high in the open and sallying frequently, occurs mostly in single-species flocks. When not breeding, the majority of tanagers remain in pairs or gather in small groups that presumably include parents and offspring, while a few, such as the White-capped Tanager and the bush-tanagers, are regularly seen in larger groups. The composition of these larger single-species groups remains unknown, but they may include offspring from multiple generations, as well as unrelated individuals. Solitary behaviour is typical of a few species after breeding, such as northern, migratory *Piranga* tanagers, which may well be unrelated to true tanagers (see Systematics). These *Piranga* species, breeding in the north-temperate region, typically maintain solitary territories on tropical non-breeding grounds, and some flowerpiercers, when not breeding, also attempt to hold exclusive patches of flowers for themselves.

In Amazonia, seasonal flooding, which can be widespread along large rivers, brings dramatic changes in the abundance of food resources in the understorey and floor of the forest and in habitats subject to inundation. Flooding causes predictable but dramatic seasonal changes in the lives of species that live on or close to the ground. No tanager in Amazonia habitually forages on the ground, and only a few, mainly *Ramphocelus*, are found low along borders. The Red-crowned Ant-tanager, a member of a genus, *Habia*, likely soon to be removed from Thraupidae (see Systematics), occurs in both *várzea* and *terra firme* forest understorey, but neither the ant-tanager nor the various species of *Ramphocelus* are likely to be strongly affected by seasonal flooding. These species, as well as other tanagers, are insulated, to some extent, from these seasonal rhythms by their diets, which include both fruit and insects. A mixed diet should provide more buffering against swings in resource availability than would a specialized diet, although the proportion of fruit-eating to insect-seeking among small tanagers such as *Tangara* can vary markedly, even in environments where seasonality of rainfall is reduced.

Breeding

The breeding behaviour of tanagers, so far as is known, does not differ appreciably from that of many other small oscine passerines. Among tanagers that have been studied, almost all species breed in monogamous pairs, hold at least loosely guarded territories, and raise one or two young, or more at higher latitudes, which stay with the adults for varying periods of up to several months after fledging. The presence of helpers, which are typically offspring of a previous generation, has been documented for a number of species. Details of breeding behaviour have been published for only a relatively small number of species, which is perhaps surprising for a group of birds that are so colourful and so well known. For the majority of tanagers, relatively little is known

The nests of Conirostrum *conebills are small, deep compact cups, often tightly woven from a mixture of plant and animal fibres. The nest of the* ***Cinereous Conebill*** *includes a mixture of plant fibres and vegetable down, from* Typha *"bulrushes", for example, and is lined with horsehair. Materials used by the Bicolored Conebill* (C. bicolor) *include grass and feathers, and the Tamarugo Conebill* (C. tamarugense) *incorporates sheep's wool as well as twigs, feathers and the midribs of* Prosopis tamarugo *leaves. Nests are often well concealed. A Rufous-browed Conebill* (C. rufum) *nest was found 2·5 m up in a blackberry* (Rubus) *thicket at the edge of a road and was camouflaged with dry blackberry leaves incorporated into its exterior. A nest of a Chestnut-vented Conebill* (C. speciosum), *a tiny cup made from leaf petioles and fibres, with no animal materials, was hidden in a curled, dead* Cecropia *leaf, hanging from a thin vine 4·5 m above the ground, at the edge of a forest bordering a road. Tamarugo Conebill nests in northern Chile were situated either on descending branches or at the outer ends of horizontal branches in the middle third of trees, possibly to escape predation by lizards, which climbed the main branches.*

[*Conirostrum cinereum littorale*, 11 km NE of Arica, Chile. Photo: Alejandro Torés]

Among populations of the ***Scarlet-throated Tanager****, red-throated males are in a minority, and males may breed in a subadult plumage, which resembles that of the female but is duller. Some male euphonias may also breed in a subadult plumage that differs from the female in having a small black face mask. During the breeding season, male Scarlet-throated Tanagers display the white bases of the feathers on their back. These icterid-like tanagers have been observed to carry long sticks to add to their nests, which are hidden in the crowns of palms, in woodpecker (Picidae) holes in* Mauritia *palm snags, or in abandoned stick nests of the Caatinga Cachalote (Pseudoseisura cristata).*

[*Compsothraupis loricata*, São Feliz do Araguaia, Mato Grosso, Brazil. Photo: Edson Endrigo]

about even the most basic aspects of breeding such as social structure and territoriality, nest architecture, eggs, and nestling and fledgling behaviour. Information on breeding by tanagers is skewed towards a few localities, with information from much of the Neotropical Region scant or lacking. The detailed life-history studies by Skutch provide the most complete data available on the breeding activities of tanagers, and almost all of his work was carried out in Costa Rica. Breeding data for several species of tanager in Trinidad are available from the studies of the Snows. Studies by S. Narosky, M. de la Peña, P. Mason and others in Argentina have provided some information for that region, and, more recently, the prolific nest-behaviour studies of H. Greeney in Ecuador have produced a good deal of useful data. There are also some unpublished data for western Colombia from Hilty. In addition, breeding data from a wide variety of sources were compiled by the Islers in their landmark monograph on tanagers.

Remarkably few breeding data are available on tanagers from anywhere in Amazonia, and information from the Andes is very spotty and incomplete, yet these are the two areas with highest thraupid diversity. Moreover, only a relatively small amount of information is available on tanagers, or other species, from the Atlantic Forest region of south-eastern Brazil, and almost none from the vast black-water/white-sand forests of southern Venezuela, the Guianas and northern Brazil. This concentration of breeding data from just a few localities leaves large gaps in our knowledge of avian life cycles, especially in major biotic regions, which are likely to differ greatly in seasonal rainfall, temperature, and soil and forest productivity.

So far as is known, the breeding seasons of tanagers coincide with those of most other small Neotropical passerines. In Middle America and northern South America north of about 10° N, breeding is at its peak between about March and the end of July, although with considerable annual variation. The Snows, working in Trinidad, discovered that, for most of the resident tropical birds in Central America and northern South America, the onset of the complete annual moult, which is an energetically expensive process, was much more predictable than was the start of breeding. The complete moult of both oscine and non-oscine passerines typically began in June, varying by little more than a month earlier or later. The Snows found that this relatively constrained time period was constant from year to year for small frugivores and insectivores, and occurred about a month after the annual rainy season began. This also is the period of the year when both plant and arthropod resources are likely to be at or near a peak in regions about 10° north of the Equator. These latitudes, they found, were far enough away from the Equator to experience distinct seasonality in rainfall, a consequence of the sun's annual north–south passage overhead and the subsequent band of heating and increased rainfall that follows a month or more after the sun's passage.

Both breeding and the annual moult, then, seem to be timed, as far as possible, to take advantage of a seasonal peak in arthropod and fruit resources. The onset of breeding is generally more variable but breeding activity typically declines sharply as moult, with its more predictable timing, begins. The onset of breeding turns out to be quite variable for tanagers, as it is for most small resident birds of Central America and northern South America. In Trinidad, for example, the Snows found that the onset of egg-laying can occur in almost any month from October through to May, usually triggered by an increase in rainfall and food supply, but for some species living in forest, where resources are likely more predictable over time than would be the case in semi-open and secondary areas, breeding can continue at a relatively low level throughout the year, with the exception of the approximately two to three months of the annual moult. Breeding and moult thus appear timed, so far as possible, to a period or periods of the year when food resources are relatively high, but it is moult, more than breeding, that dictates the cycle. A similar pattern, beginning almost exactly six months later, emerges in the Southern Hemisphere, where moult immediately follows, or even truncates, breeding and becomes progressively more synchronized in its timing as one moves farther away from the Equator. As may be expected, breeding and moult periods are less clearly defined in areas close to the Equator, where rainfall patterns are apt to be bimodal or nearly aseasonal. Thus, the seasonal breeding patterns, or lack of them, that we observe for tanagers should be viewed in the context of food resources and in the context of the annual moult, because these are the two most energetically costly activities that must be faced by tanagers, as well as by most other small tropical birds, each year.

The onset and duration of breeding are affected by many factors, but most importantly by the abundance of food. For

The nests of Ramphocelus *tanagers are built entirely by the females. The female* ***Scarlet-rumped Tanager*** *begins with a base of large leaves before weaving thick walls of fibres and rootlets, which she lines with fine hair-like fibres. Nests are usually several metres above the ground in dense shrubs or thickets, but have also been found among sugar cane and in coarse grass and ferns. Females have been observed to steal material from neighbouring nests: territorial defence of nest areas, weakly developed in most tanagers, is almost non-existent in* Ramphocelus. *In Costa Rica, Cherrie's Tanagers* (R. costaricensis) *have been found nesting just a few centimetres apart.*

[*Ramphocelus passerinii*, Costa Rica.
Photo: Marco Saborío]

example, a food-resource peak for tanagers feeding on foliage-eating insects is likely to occur at the onset of the major rainy season, slightly ahead of the peak in fruit abundance, which, in turn, precedes a resource peak for grass seeds or arthropods on the forest floor. In equatorial regions, such as the mountains of Colombia and Ecuador, double rainfall peaks, in March–April and October–November, respectively, may result in a more bimodal breeding pattern for some species of tanager. Species such as the Blue-grey and Palm Tanagers, which breed around human habitations where food resources may be plentiful almost throughout the year, may have prolonged breeding seasons, with at least some breeding activity in almost every month of the year. On the other hand, species that depend upon specialized resources such as nectar may have breeding patterns more closely matched to flowering peaks, and unrelated to the patterns shown by frugivores and insectivores. In Guatemala, for example, Skutch found that the Cinnamon-bellied Flowerpiercer usually bred from November to January, well ahead of other species, but timed to coincide with peak flower abundance.

Among those tanagers which have been studied, breeding systems are almost universally monogamous. There is almost no information from marked populations, but observational evidence suggests that monogamy is the norm in the family. *Ramphocelus* tanagers may on rare occasions be polygamous, in part because they are typically found in groups throughout the year. During his long observations of Cherrie's Tanager, Skutch documented one or more cases of presumed polygamy but noted that, even among females nesting relatively close together, several males were almost always present; male participation in the feeding of the young, however, was often less than half that of females, and in three instances no male was present to feed the young, or a male only rarely did so. Skutch believed that these represented exceptions, involving females that may have formed temporary pair-bonds with males or females that had lost a mate, and he concluded that monogamy was the predominant mating system even for Cherrie's Tanager. Although Skutch did not mark individuals, his long and detailed studies of many tanager species in Costa Rica indicate that monogamy is surely the predominant mating system, if not the only one, among thraupid species studied to date. Among a small number of marked pairs of nesting *Tangara* tanagers observed in western Colombia, Hilty noted that only pairs, or pairs and helpers, attended nests. In addition, colour-ringed pairs of Grey-and-gold Tanagers, Blue-necked Tanagers, Golden-hooded Tanagers and Rufous-throated Tanagers remained as pairs throughout a 16-month observation period. Few data exist on the long-term duration of pair-bonds, but for these Andean *Tangara* species the bond may remain stable for at least a year or more. Multi-year ringing projects could provide valuable information on population movements and pair-bond stability, but few such studies have been conducted with tropical passerines. One exception to this is a long-term ringing project carried out in the Henri Pittier National Park, in northern Venezuela, but to date little information has been published from that study.

In addition to *Ramphocelus* tanagers, all of which typically are found in single-species groups, the White-capped, Scarlet-throated, Azure-rumped (*Tangara cabanisi*), Grey-and-gold, Turquoise and Swallow Tanagers all regularly occur in groups of their own. Others, such as the Red-billed Pied Tanager, Oleaginous Hemispingus, Paradise Tanager, Green-headed Tanager, Purple Honeycreeper and Red-legged Honeycreeper, are found in both single-species and mixed flocks. Whether the social systems of these gregarious species are more complex than monogamy remains unknown. Observations at nests of Azure-rumped and Turquoise Tanagers suggest that nestlings may be fed by up to five or six individuals, but apparently no more than a single adult pair is involved in nest-building, egg-laying and incubation.

Courtship feeding, in which a male feeds a female, was recorded for several *Tangara* tanagers that Skutch studied in Costa Rica, among them the Golden-hooded Tanager, Silver-throated Tanager and Speckled Tanager, as well as the Blue-grey Tanager and Green Honeycreeper. In courtship feeding, known also as nuptial feeding, the male feeds the female away from the nest, or occasionally at the nest. Skutch further notes that, while courtship feeding typically involves the feeding of females by the males, occasionally females have been noted feeding males. Courtship feeding has also been recorded for *Piranga*, *Chlorophonia* and *Euphonia*, genera currently included in Thraupidae but now thought to belong elsewhere (see Systematics). It is likely that this behaviour is more widespread than reported. Occasionally, the male brings food to the nest prior to the hatching of the eggs, and may even feed it to the female, but this behaviour, near

the end of the incubation stage, represents anticipatory food-bringing, rather than true courtship feeding. Delivery of food before the hatch has been observed for *Ramphocelus* tanagers in Costa Rica and Panama.

Thraupid nests are, for the most part, rather unremarkable, being simple open cups built among forked branches in bushes or trees. They are typically well constructed, consisting of a fairly thick layer of dry leaves, shredded fibres, ferns, dry grass, fibrous plant material and moss. A thin layer of rootlets and finer material is usually used as a nest lining. Those of Grey-headed Tanagers are notable for their frail and flimsy construction. Blue-grey Tanagers and Palm Tanagers build loosely constructed cup-nests in broken tree cavities, stubs, palms, or cracks or crannies in buildings, under eaves, or on beams inside buildings. Blue-grey Tanagers also may usurp nests of other species, most conspicuously those of Rufous-fronted Thornbirds (*Phacellodomus rufifrons*) in Venezuela, but also tyrant-flycatcher nests, including those of Boat-billed Flycatchers (*Megarynchus pitangua*). Females of the enigmatic Swallow Tanager build a weak cup at the end of an earthen tunnel in a bank, in a cavity in a stone wall, in a tree hole, or even in a dark recess beneath a bridge. As a whole, tanager nests are sufficiently durable for a single nesting attempt, but even the thickest and most well-constructed nests deteriorate quickly in the humid environments, and it is usual for a new nest to be built prior to a second nesting attempt. Skutch reported a few examples in which a female Cherrie's Tanager attempted to reuse a nest from an earlier, failed nesting attempt, but without success. In one case, a pair of Rusty-margined Flycatchers (*Myiozetetes cayanensis*) stole much of the nest material before a second clutch could be laid. In the Andes, some *Tangara* tanagers build little cup-nests inside pockets or recesses in clumps of moss and epiphytes hanging beneath limbs, thus achieving some overhead protection. In cloudforests, where the surface of almost every twig, branch and trunk is covered with epiphytes and moss, such nest-sites are exceedingly cryptic and difficult to spot, except by watching the comings and goings of the adults, or by hearing the begging cries of the young when the adults return with food. In western Colombia, nests of the Rufous-throated Tanager and Golden Tanager have been discovered in hanging clumps of moss, and other montane *Tangara* may use similar suitable sites at least occasionally.

Domed or enclosed nests are, on the basis of present knowledge, constructed only by the enigmatic Bananaquit, the taxonomic affinities of which have, until recently, been disputed, and by members of the genera *Chlorophonia* and *Euphonia*, both of which have now been found to be unrelated to other thraupids (see Systematics). The nest of the Bananaquit differs from that of all other tanagers in being thick-walled, entirely enclosed, ovoid or globular in shape, and with a small, downward-facing entrance opening near the bottom. There is considerable variation in its size and shape, and it may be placed low or high and often in a rather exposed position. The construction material is equally variable, and can consist of whatever is immediately available, including coarse or fine vegetable fibres, grass, bamboo leaves, strips of leaves and pieces of vines, weed stems, tendrils, thin papery bark and moss. Bananaquits are energetic nest-builders and both sexes build auxiliary nests for sleeping. These "dormitory nests" resemble breeding nests, but are usually less well constructed. Females, when not nesting, also may use old nests as dormitories for extended periods of time.

Nests of tanagers are usually built by both members of a pair, although females, especially those of *Tangara*, typically contribute much more material than males and carry out all or most of the building work. In case of the Red-legged Honeycreeper, all nest construction is performed by females. The length of time required for building is known for only a few species and generally varies within the range of about 3–6 days, but it can sometimes take longer. Factors that influence the length of time required for nest construction are unknown. Bananaquit nests, although considerably more substantial than the cup-nests of other tanagers, are built by a single industrious individual or a pair in 4–5 days. For most species studied by Skutch in Costa Rica, more nest-building took place during the morning hours than in the afternoon. The Red-legged Honeycreeper was exceptional in that it brought in nest material mainly during the hours of late morning and early afternoon. The rates of delivery of nest material varied widely. A female Red-legged Honeycreeper brought material 11–14 times per hour during mid-day periods, but her rate of construction was irregular and long periods passed with no building work done. A female Silver-throated Tanager watched by Skutch in Costa Rica was observed bringing material to a nest a record 68 times during a two-hour period between 06:25 hours and 08:25

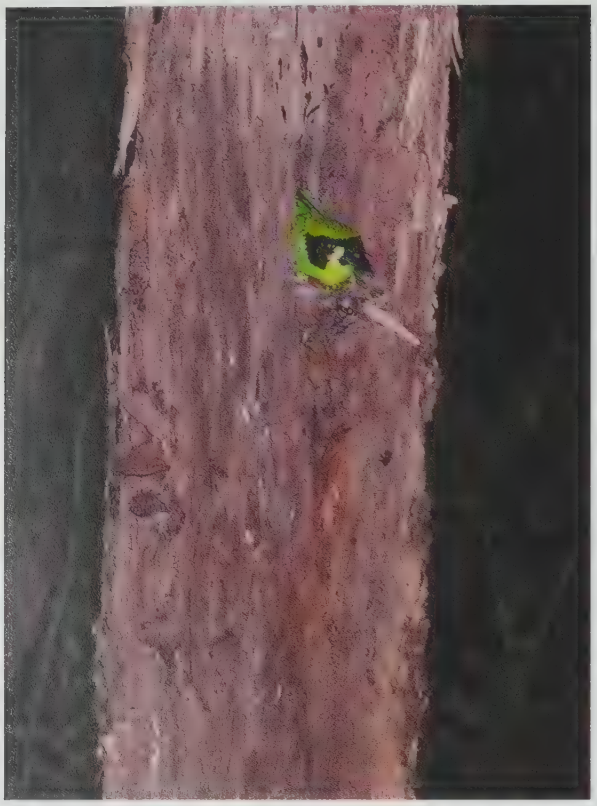
Piranga *tanagers build rather frail, poorly constructed nests. That of the* **Lowland Hepatic-tanager** *is a flattish cup, loosely woven from dry leaves, roots and grass stems. In some* Piranga *species the female is said to build the nest alone, accompanied by her mate; in others, the male is recorded as carrying material to the female as she builds the nest. Here, the male appears to be involved in nest-building, too, while the female waits her turn.*

[*Piranga flava saira*, Estrada BR-153 Km 8, Palmeirante, Tocantins, Brazil. Photo: Dante Buzzetti]

The nest of the ***Black-legged Dacnis*** *differs markedly from those described for congeners such as the Scarlet-thighed Dacnis* (Dacnis venusta) *and Yellow-bellied Dacnis* (D. flaviventer), *which are frail, shallow open cups supported by branches. One Black-legged Dacnis nest, in Intervales State Park, in São Paulo, Brazil (the location of this picture), was situated about 6 m above the ground and attached to at least two twigs in the crown and outermost part of a narrow-trunked* Rapanea ferruginea *tree. It was made chiefly from live* Usnea *lichen. Dangling lichen completely hid the egg-chamber, which was a compact, hanging pouch-like structure, as in the nest shown here, apparently completely enclosed except for a small entrance hole. Another nest described was a partially concealed, basket-like cup 5–8 cm in diameter, suspended from epiphytes 20 m up and half-way out on a limb of a large* Schizolobium parahyba *tree in a cacao plantation. Black-legged Dacnis nests are sometimes built relatively close to one another (in one case as close as 15 m), with no aggression between pairs. It has been suggested that this species may nest in loose groups close to favourable food resources. The nest of the Blue Dacnis* (D. cayana) *also differs from those of its congeners, being a deep, almost pouch-like cup of soft fibres and seed down, suspended between leafy twigs in the outer parts of trees.*

[*Dacnis nigripes*, Intervales State Park, Ribeirão Grande, São Paulo, Brazil. Photo: Edson Endrigo]

hours and again 13 times during a 24-minute period from 15:30 to 15:54 hours. At a rate of a little more than once every two minutes, including time spent arranging nest material, this likely represents close to the upper limit possible for any bird, unless construction material is immediately at hand. During a six-hour period, the male made only 4–5 contributions to his mate's industrious efforts, but he was seen to feed her 5–6 times and she was possibly fed more. Male tanagers regularly accompany females to nest-sites, even when they do not bring material. Males of *Thraupis* tanagers and of the Grey-headed Tanager help with nest construction, but the nests of *Ramphocelus* tanagers are built entirely by females.



Above-ground height of tanager nests is only weakly correlated with the stratum in which the species in question forages. Edge, garden and undergrowth species, such as *Ramphocelus* tanagers and the Grey-headed, White-lined and Diademed Tanagers (*Stephanophorus diadematus*), forage low down and usually build their nests within a few metres of the ground. Species that forage well above ground along forest borders and in light or semi-open woodland may locate their nests somewhat higher. Three nests of the Hooded Tanager, for example, were all placed 8–10 m up and in semi-open situations. On the other hand, nests of tanagers inhabiting the canopy or subcanopy are recorded at both high and low levels. A White-throated Shrike-tanager (*Lanio leucothorax*) nest in Costa Rica was found in a low bush near a forest stream, even though this species is most frequently found at middle heights or higher in rainforest. The only reported nest of the Green-and-gold Tanager, a subcanopy and canopy species in Amazonia, was sited only 2 m up inside rainforest in south-eastern Peru. Similarly, a nest of the White-shouldered Tanager in Trinidad was located only 1–1·5 m above ground in the forest undergrowth; it is worth noting, however, that in Trinidad this species occurs both high up and low down inside forest, and thus occupies a much broader niche space than on the mainland, where it is usually at middle levels or higher and often near forest treefall openings. In Costa Rica, nest heights of the Silver-throated and Golden-hooded Tanagers, two species that typically forage at middle levels or above, varied widely, ranging from 1 m to 28 m above the ground, and nests of Blue-grey Tanagers have likewise been recorded from ground level to 30 m up. The highest recorded tanager nests appear to be one of a Paradise Tanager, a canopy and emergent-tree specialist in Amazonia, which was located 31 m up in a small outer branch of a kapok tree (*Ceiba pentandra*) in south-eastern Peru; and a nest of a Grey-and-gold Tanager estimated at 30–32 m up on a mossy branch in the valley of the Anchicayá River, in west Colombia. Some *Euphonia* nests are even higher up, as detailed at the end of this section. The nests of several Amazonian/Guianan treetop tanagers, including the Red-billed Pied Tanager and the Blue-backed Tanager (*Cyanicterus cyanicterus*), remain undiscovered and may be placed even higher; both of those species are almost always found very high up in rainforest. At least two species of *Chlorospingus* and a half-a-dozen or more of *Euphonia* are known to build nests at ground level on the tops or sides of roadbanks, but none build on flat, level ground and few other tanagers, as traditionally classified, nest on the ground. One exception is the Red-shouldered Tanager, a savanna-scrub species that has been reported as nesting on the ground in Suriname. Several species, including the Black-faced Tanager, Masked Crimson Tanager, Black-goggled Tanager and Grey-headed Tanager, are known to nest close to the ground on occasion. The Black-and-white Tanager has been suspected of nesting on or close to the ground and in grass, but its nest remains undiscovered.

Clutch size is known for a small number of tanagers and appears to vary with latitude, much as reported for other passerines. In general, the average number of eggs laid by tanagers in lowland tropical latitudes is two, or occasionally three. Clutch size increases to 3–4 at the edge of or beyond tropical latitudes. Two species in southern Brazil, namely the Black-goggled Tanager, which also has a separate Andean population, and the Golden-chevroned Tanager, the ranges of which lie close to the southern border of the tropics, often have clutches of three eggs, as does the Yellow-winged Tanager (*Thraupis abbas*) in Mexico, at the northern end of the tropics. In Costa Rica and Panama, Skutch reported that in more than 30 nests of Blue-grey Tanagers the clutch was always of two eggs, but, of three nests in Guatemala, two contained clutches of two and the third held three eggs, suggesting that a slightly larger clutch might be expected in the more northerly country. In temperate latitudes of central Argentina, the Diademed Tanager, Blue-and-yellow

All published information about the breeding of the ***Red-necked Tanager*** *comes from captive birds, which are reported as building deep cup-shaped nests of grass. The materials used by this wild bird seem quite different, including large leaves and the shoots of vines or creepers; and video material available at the Internet Bird Collection shows a nest that appears to consist mainly of slender twigs. The available information on captive birds does not extend to whether one or both of the pair were involved in building the nests. The female alone incubates the eggs, but both sexes feed the nestlings.*

[*Tangara cyanocephala corallina*, Alagoas, Brazil. Photo: Anita Studer]

Although a number of tanager species have occasionally been recorded as breeding in holes, only the Swallow Tanager (Tersina viridis) *does so habitually. The few nests of the* ***Green-and-gold Tanager*** *that have been described previously have been placed low down (from 75 cm to 2 m), well concealed and woven tightly to the base of a palm frond or fern. One was at the base of an* Asplenium serratum *fern, 1·8 m above the ground, in an unknown understorey tree. The cup-shaped nest was made from rootlets and dried fronds and attached at its bottom by fern rootlets and old fern petioles.*

Tanager and Sayaca Tanager typically lay four eggs. Two striking exceptions to this pattern of increasing clutch size with increasing latitude, however, suggest that clutch size may be more complex than a simple geographical pattern. The White-rumped Tanager, a widespread species of *cerrado* mixed grassland and scrub in south-central Brazil, and still well within tropical latitudes, lays clutches of four or, less often, three eggs. The Swallow Tanager, a hole-nesting species that breeds in mountainous regions across northern Venezuela and southward in the Andes, also lays 3–4 eggs. Cavity-nesting species typically have higher rates of fledging success, an advantage offset by the fact that suitable holes or cavities are often in short supply. The large clutch size of the Swallow Tanager may have less to do with geographical variation than with selection factors resulting from nest-site choice. White-rumped Tanagers, however, build open cup-nests, as do most other tanagers. Larger clutch sizes are well documented for all species of *Chlorophonia* and *Euphonia*, as well as for North American breeding *Piranga*, and these species, now believed to belong in other families (see Systematics), are discussed at the end of this section.

Clutch size information exists for so few species of true tanager that, beyond the small number of examples cited above, few meaningful generalizations can be made. There is, for example, very little information on the clutch size of tanagers occurring at high elevations within tropical latitudes. Does clutch size increase with declining average temperatures, or does it vary between arid and humid regions, or between forest and grassland? For a family of which so many species, especially in the Andes, are so eagerly sought by avid birders and other naturalists, the lack of breeding data is remarkable. Breeding data are almost completely lacking for most species of high-Andean genera, including *Buthraupis*, *Anisognathus*, *Iridosornis*, *Dubusia*, *Cnemoscopus*, *Hemispingus*, *Urothraupis* and *Thlypopsis*, as well as highland species of *Dacnis* and *Conirostrum*. Aside from Skutch's study of the Slaty Flowerpiercer in Central America, there is an almost complete absence of breeding data for *Diglossa*, another large, predominantly high-Andean genus.

From the limited information available, tanager eggs are slightly to heavily pigmented. The ground colour can be cream or white, but is more usually pinkish, grey, bluish-white, pale to bright blue, blue-green or other, similar shades or combinations, and is almost invariably marked with fine to coarse spotting, blotches or scrawls of reddish, purple, lilac, brown or black; the markings are often more heavy, forming a dense wreath, at the larger end of the egg. The cavity-nesting Swallow Tanager is an exception in that its 3–4 eggs vary from being completely white to being lightly marked with dark spots and scrawls, a pattern typical of most hole-nesting species, which also typically have white eggs.

So far as is known, incubation is undertaken solely by female tanagers, although data are available for only a relatively small number of species. An exception is provided by the Rosy

Euphonias and chlorophonias build covered nests, rather than the open cups constructed by most thraupids. The euphonias include some species which nest near the ground, and others which nest higher in the canopy than any known tanager species. The ***Violaceous Euphonia*** *builds a globular nest with a side entrance, usually well concealed among epiphytes or vines. Occasionally nests have been found in niches high on mossy, well-vegetated roadside banks. Violaceous, Thick-billed* (Euphonia laniirostris) *and Golden-sided Euphonias* (E. cayennensis) *have all been documented as using nests of other birds, refurbishing these for their own purposes.*

Thrush-tanager, an odd species the taxonomic affinities of which have been questioned and which may ultimately be removed from the family. In Venezuela, male Rosy Thrush-tanagers have been reported to incubate eggs, alternating stints with the female. Information on the time of day at which tanagers lay their eggs is based on the studies of Skutch, who noted that eggs were most frequently laid in the early morning between 05:30 and 06:30 hours, and that incubation started on the day when the last egg was laid.

Similarly, data on the constancy of incubation stem mostly from the work of Skutch, whose detailed life-history studies included no fewer than 13 species of tanager in Costa Rica and a further eight species formerly regarded as tanagers. Females generally incubate throughout the night, as well as during much of the day. During a watch of over 12 hours, the incubation constancy of a female Speckled Tanager was 79·8%, among the highest of any tanager that Skutch observed. During that period, the female had 14 incubation sessions each of 30–53 minutes, the average session lasting for 39·7 minutes. Between incubation stints she took rests ranging from 2 to 27 minutes, with an average recess time of 10·1 minutes. During this same period of time, the male fed the female ten times, nine of which were at the nest and the other when she was nearby. Data collected during a second all-day nest observation yielded similar results, the longest incubation period being of 77 minutes, and the longest period of "egg neglect" only 23 minutes. Data for other species of tanager studied by Skutch, including the Blue-grey, Grey-headed, Cherrie's, Crimson-backed, Golden-hooded, Plain-colored and Silver-throated Tanagers, the Green, Red-legged and Shining Honeycreepers (*Cyanerpes lucidus*), the Slaty Flowerpiercer and the Bananaquit, are similar, but with somewhat lower incubation constancy. The lowest incubation constancies were recorded for the Grey-headed Tanager and a female Blue-grey Tanager, with respective averages of 62·6% and 66·2%. The low incubation constancy observed for Grey-headed Tanagers may be associated with this species' behaviour of preferentially foraging with army-ant swarms, which may be distant from the nest-site, thus requiring longer commuting times and possibly also additional time involved in searching for swarms. Male tanagers were not observed to feed their mates at or near the nest during these watches. Incubation constancies calculated by Skutch were obtained largely during periods of fair weather. The data gathered during two rainy afternoons were dramatically different, when one female Shining Honeycreeper incubated continuously for 179 minutes and, between 13:00 and 18:00 hours, was absent from her eggs for only 12 minutes during the entire five-hour period. During a second period of observation, this same female incubated continuously for 4 hours and 2 minutes, from 14:21 hours until nightfall, sitting through an hour and a quarter of rainfall. Overall, the incubation constancy of tanagers observed by Skutch in Costa Rica varied within the range of about 60–80% of daylight hours.

*The leaf collected by the **Scarlet-rumped Tanager**, pictured earlier (see page 126), forms part of the nest here, and the same bird, a female, is now incubating her eggs. As with almost every tanager species, incubation is undertaken solely by the female, attended and fed to some extent by her mate. The Scarlet-rumped Tanager lays two eggs, rarely three, on consecutive days. The eggs are pale greyish-blue or, more uncommonly, greenish-blue, and marked with small black or brown spots, or fine irregular lines, mainly around the larger end. The incubation period for this species is twelve days.*

[*Ramphocelus passerinii*, Costa Rica. Photo: Marco Saborío]

*In Taquaritinga do Norte, in Pernambuco, Brazil, on 21st January 2000, five different pairs of **Seven-colored Tanager** were seen nest-building in different arboreal bromeliads up to 15 m above the ground. The total area which they occupied was slightly larger than 500 m^2, suggesting that breeding territories are relatively small. It appears that for breeding this species needs large bromeliads and cannot survive in secondary forest without them; conversely, it has been observed in gardens and orchards with bromeliad-laden trees. Its already small range in Brazil's Atlantic Forest is shrinking fast and numbers are also caught for the cagebird trade. This species is listed as Vulnerable.*

[*Tangara fastuosa*, Alagoas, Brazil. Photo: Anita Studer]

Among tanagers, as with other passerine families, clutch sizes are smaller in the tropics than at higher latitudes. There appears, however, to be no information as to whether the clutch size of the ***Lowland Hepatic-tanager*** *varies from the tropical north of its range, in Guyana and Suriname, to southern Brazil, Paraguay and Uruguay. The Highland Hepatic-tanager* (Piranga lutea), *traditionally considered conspecific with the Lowland species, produces two eggs in Trinidad, and the Northern Hepatic-tanager* (P. hepatica), *also often treated as a race of "Hepatic Tanager", produces up to five eggs (average four) in the southern USA.*

[*Piranga flava saira*, Minas Gerais, Brazil. Photo: Anita Studer]

Incubation periods for most tanager species vary from about 12 days to 14 days, with occasional records of 15 days. In a possible exception to this, the hole-nesting Swallow Tanager is reported as having an incubation period of 13–17 days. Nestling periods are variable, but the shortest times are for species that nest low down, that of *Ramphocelus* in Costa Rica, for example, being only 11–13 days. Otherwise, *Tangara* species have a nestling period of 13–16 days, the Bananaquit one of 17–19 days, and *Thraupis* 16–20 days. Even longer nestling periods were recorded for *Euphonia* and *Chlorophonia* (see end of this section), both of which build relatively "safe" covered nests and regurgitate mainly a low-protein diet of fruit pulp to their nestlings.

On hatching, the altricial tanager nestlings are blind and have only minimal natal down. They are brooded only by the female, but fed by both sexes. The feeding efforts of the male parent are variable, typically less than those of the female initially but, in some instances, exceeding the contribution of the female when the nestlings are older. For almost all species reported, the nestlings are at first fed primarily with arthropods, especially insects, but as they grow their parents bring a mixed diet of arthropods

Tanager nestlings are at first fed primarily with arthropods, especially insects. But as they grow, their parents bring a mixed diet of arthropods and fruit, the proportions perhaps depending on whether the adults are more insectivorous or more frugivorous. Birds given mostly animal food tend to grow more quickly. The rather long nestling period of the ***Palm Tanager***, *17–21 days, may suggest that the young are fed mostly on a low-protein diet of fruit. This adult is accumulating fruit to take back to the nest.*

[*Thraupis palmarum melanoptera*, Coroico, La Paz, Bolivia. Photo: Joe Tobias]

and fruit. Helpers, which are believed to be the breeding pair's offspring from previous broods, are reported for a number of *Tangara* tanagers, including the Golden-hooded, Golden, Plain-colored, Turquoise, Azure-rumped and Rufous-throated Tanagers, as well as for the White-capped Tanager and the Red-throated Ant-tanager, the last-mentioned now believed to be more closely related to cardinalids than to the Thraupidae (see Systematics).

Territorial defence of nest areas is weakly developed in most tanagers, and almost non-existent in *Ramphocelus* tanagers. In Costa Rica, Skutch recorded that nests of Cherrie's Tanagers were occasionally only a few centimetres to a few metres apart, while in other cases they were widely separated. Regardless of spatial separation of nests, pairs or members of groups displayed little or no aggression towards one another. The clearest evidence of territorial behaviour derives from the *Diglossa* flowerpiercers and the Tit-like Dacnis (*Xenodacnis parina*), which breed in patchy, stunted woodlands at high elevations. Flowerpiercers, many of which are highly nectarivorous, are notably territorial when breeding. When not breeding, pairs separate on individual feeding territories, which continue to be aggressively defended but are somewhat fluid, depending upon the distribution of suitable nectar resources. Territoriality of many flowerpiercers extends to conspecifics and, when not breeding, even to individuals of the opposite sex, which often hold separate territories. In addition, flowerpiercers attempt to exclude hummingbirds from their territories, although large hummingbirds may dominate smaller species of *Diglossa*. In Mérida, in south-west Venezuela, Sparkling Violetears (*Colibri coruscans*) have been seen aggressively supplanting Merida Flowerpiercers in flower gardens.

Distraction displays, or feigning displays, towards potential nest predators are almost unknown for tanagers. Skutch noted that, on rare occasions, an adult Grey-headed Tanager gave a rather poor feigning display when a human visited a nest. He also noted that an adult Golden-hooded Tanager once became very agitated and emitted forceful "chip" notes as he examined a nest, but he did not observe any injury-feigning display. E. O. Willis reported a weak distraction display for the Red-throated Ant-tanager.

Observations of a single pair making more than one nesting attempt during a breeding season have been reported for several tanagers in Costa Rica, but a number of factors may determine how frequently this occurs and, furthermore, there is little information on second-brood attempts from the Andes or Amazonia. True second broods, in which a second nesting is attempted following a previously successful nesting, are probably less frequent in occurrence than are incidents of renesting following nest failure. Skutch, however, documented more true second broods than replacements for Golden-hooded Tanagers, but he reasoned that nest failures more often resulted in a pair moving some distance away, where he was unable to detect them. For Cherrie's Tanager, renesting attempts following failure were common, so frequent in fact that Skutch stated "These birds lose so many nests to predators that they probably could not maintain their population if they did not try repeatedly to rear a brood." Golden-hooded Tanagers, too, often attempted to raise true second broods, and sometimes even third broods, in a season. Intervals between the departure of a brood and the next laying period were usually short, in the range of about 9–23 days, but occasionally much longer. In the case of one very short nine-day interval, the parent pair began to build a second nest nearby only two days after fledging one young from the first nest. In the case of Cherrie's Tanagers, females often built new nests a few metres away from preyed-on nests, and the interval between the loss of nest contents and the laying of the first egg of a replacement clutch was only about 7–10 days. In Costa Rica, Grey-headed Tanagers frequently built replacement nests following nest failures. Intervals between failure and the laying of the first egg of a new clutch were on average about 7–9 days, but occasionally more than three weeks. One pair made three attempts in quick succession, with intervals of only 8–9 days between renesting attempts, and successfully fledged two young from the third nest. Silver-throated Tanagers, which have one of the highest fledging successes reported, often raise two and possibly three broods during their long March–September breeding season in Costa Rica. Intervals between the departure of one brood and the first eggs of another breeding attempt varied from eight days to 45 days.

Golden-hooded Tanagers commonly reuse a nest even after losing eggs or nestlings in an earlier attempt. So strong is site-fidelity that Skutch documented several examples in which a pair used the same nest three times. In one remarkable example, a pair built a nest 2 m up in a small orange tree, but never laid in it. In the next year, the tanagers built a new nest in exactly the same site, reared one young to fledging, and twelve days later laid the first of two more eggs, which subsequently disappeared. This twice-used nest then remained empty for 78 days, before being

*Living in semi-open areas, the **Black-faced Tanager** places its nest low down, sometimes in grass. There is little other information on the breeding of this species or its congener, the Cinnamon Tanager* (Schistochlamys ruficapillus)*, except that both lay two eggs. This bird is approaching the nest with a beak full of insects. The diet of this species seems evenly divided between animal and vegetable matter. One pair fed regularly on small, very hot peppers, though one imagines that, as with humans, the taste for these is likely to be confined to the adults.*

[*Schistochlamys melanopis olivina*, São Carlos, São Paulo, Brazil. Photo: Haroldo Palo]

Flying insects, particularly wasps and ants, make up a high proportion of the prey of the ***Western Tanager*** *when they have young. This species also takes advantage of termite (Isoptera) mating flights. A study of Western Tanager nests in Boulder, Colorado, found that nesting success varied annually, from 11·3% in 2000 to 75·3% in 2001. Predation was the primary cause of failure. Parasitism by Brown-headed Cowbirds* (Molothrus ater) *occurred in seven of 17 nests found during egg-laying or incubation. Clutch size averaged 3·8 in ten unparasitized nests, but only 2·4 in eight parasitized nests. Brood parasitism dramatically reduced the number of fledglings produced per nest.*

[*Piranga ludoviciana*, USA.
Photo: Kevin Smith/VIREO]

remodelled. Two more eggs were once again laid, but this third attempt also failed when the nestlings abruptly disappeared.

Comparisons of nesting success of thraupids reveal surprising variability among species. Of 35 Golden-hooded Tanager nests in Costa Rica for which the success, in terms of fledging at least one young, was known, 25 failed, yielding a low success rate of just 28·6%. Of 21 nests found before incubation began, the success rate was even lower, at 23·8%. The hatching success of 40 eggs was 57·5%, but the percentage of eggs that produced fledglings was only 20%. For hatched eggs, the percentage of hatchlings that fledged was 34·8%, somewhat higher than the overall nesting success. By whatever criteria are applied, the nesting success of Golden-hooded Tanagers is remarkably low. Comparable figures for the Silver-throated Tanager, a more forest-based species found in the same area, were substantially higher, including an overall nest success of 54·3%, and a success rate of 50% for nests found before the incubation stage; hatching success was 59·6%, and 44·7% of eggs produced fledglings. Moreover, the success rate for hatchlings rose to 75%, more than double that of the Golden-hooded Tanager. These examples, both based on the sample of 35 nests with known outcome, may represent extremes for tanagers, with Golden-hooded Tanagers among the least successful and Silver-throated Tanagers among the most successful. The reasons for such disparity, however, are difficult to identify with present knowledge and are unlikely to be revealed without substantial samples from other areas, especially from sites where the impact of human-caused environmental factors in minimized.

Skutch presented similar nesting-success data for other tanagers, verifying that overall nesting success is low, but generally somewhere between the values for the Golden-masked and Silver-throated Tanagers. Thus, of 163 nests of Cherrie's Tanager, only 38·6% were successful and 41·5% of eggs produced fledglings; the percentage of eggs that hatched was 58·4%, and the percentage of hatchlings that fledged was 71%. Of 24 Grey-headed Tanager nests of known outcome, 37·5% produced at least one fledgling, a rate remarkably similar to that of Cherrie's Tanager. A lower hatching rate, of only 49%, was attributed by Skutch to the female Grey-headed Tanager's longer incubation recesses, sometimes more than an hour, and an incubation constancy of only 62·6%, which Skutch believed to have resulted from the greater distances over which females of this habitual army-ant follower might have had to commute to find food, as well as the species' notably thin nest, which failed to provide insulation for the eggs.

Predation is suspected in the cause of many nest failures of tanagers, but, because it is seldom observed, the identity of the predator can rarely be proved. When nest contents are removed without evidence of damage to the nest or without any trace of feathers or eggshells, snakes are often implicated; this is because they swallow nest contents whole and are unlikely to damage the nest itself. When damage is evident, or fragments of eggshell, skin or feathers are present, mammalian predators are suspected. Predation of nest contents by other birds is more difficult to trace, because of the variable nature of attacks. An extreme example from Costa Rica illustrates the problem of verifying avian nest predation. In this case, Skutch watched an American Swallow-tailed Kite (*Elanoides forficatus*) as it swooped down and snatched an entire nest with nestlings of a Golden-hooded Tanager; circling overhead, the kite extracted the nestlings and then dropped the nest, allowing it to float earthwards at some distance. The open cup-nests of tanagers offer little protection from predators beyond being well hidden in foliage or placed in cryptic sites, such as within hanging clumps of moss. Enclosed nests of Bananaquits, as well as those of *Chlorophonia* and *Euphonia* species, may offer additional protection because the nest contents are completely encapsulated and the small nest opening may be difficult to locate. Unfortunately, there is little information on the nesting success of Bananaquits, and it is not known whether their better-built nests lead to increased success rates.

Brood parasitism by Shiny Cowbirds (*Molothrus bonariensis*) has been reported for at least eight species of tanager, and it is probable that a few others are occasionally victimized. Cowbird parasitism may affect relatively few species of tanager, however, because most do not occur in the open habitats preferred by the cowbirds. Fly larvae (Diptera) are occasional parasites of nestlings. For example, Skutch reported that the head of one nestling Grey-headed Tanager appeared infected with fly larvae.

Information on the length of the post-fledging dependency period is spotty. In Costa Rica, Skutch reported that young Bananaquits, once they leave the nest, are rarely seen again in the company of their parents. On the other hand, Silver-throated

Euphonias and chlorophonias build covered nests. So far as is known, females of both genera lay clutches of four eggs, which is twice as many as small tropical passerines that build open cup-nests, as do the majority of tanagers. The ***White-lored Euphonia****, an Amazonian forest-canopy species, regularly nests 30–35 m above ground. Its football-shaped nest is hidden in recesses in clumps of epiphytes, especially on the sides of large branches of emergent kapok trees* (Ceiba pentandra)*, among moss or ferns, or on the sides of spiny palm trunks. Because the nests are high out of sight and well concealed, there are few data on breeding for this species. For other euphonia species, however, both incubation and nestling periods are known to be much longer than in the majority of "true" tanager species. One clutch of the Spot-crowned Euphonia* (Euphonia imitans)*, for example, was incubated for 18 days, and the nestling periods in the Thick-billed* (E. laniirostris) *and Violaceous Euphonias* (E. violacea) *are up to 21 days. The nestlings are fed mainly with fruit pulp regurgitated by the adult, a low-protein diet which explains the slow maturation compared with true tanagers. The chicks of both* Chlorophonia *and* Euphonia *are typically not feathered until they are 15 or more days old.*

[*Euphonia chrysopasta*, Cristalino Jungle Lodge, Alta Floresta, Mato Grosso, Brazil. Photo: Dante Buzzetti]

In a study of the parental care of the ***Black-capped Tanager*** *in north-eastern Ecuador, the adults contributed with an almost equal amount of food, the male making slightly more visits (53·1%). Each nestling was fed at an overall rate of about six times an hour. The female generally brooded the young after bringing food to them, and the male sometimes passed to her the food which he brought but usually fed the young directly. On the day of hatching, both adults regurgitated food for the nestlings; after this, they fed them with whole insects and small berries, and a pale "mush" probably consisting of mashed* Cecropia *fruit.*

[*Tangara heinei*, La Planada Nature Reserve, Nariño, Colombia. Photo: Patricio Robles Gil/ VIREO]

Tanager fledglings hide in foliage and continue to be fed by their parents, initially by both sexes and later primarily by the female, for a period of days to weeks. Skutch observed young Silver-throated Tanagers in Costa Rica being fed until late October, well beyond the breeding season, which ends by September. Young Cherrie's Tanagers fly weakly on leaving the nest, and they remain mostly hidden in shrubbery and thickets while their parents continue to bring food to them for two to three weeks, the female again being the more attentive of the two parents. In Costa Rica, a marked fledgling of this species only two weeks out of the nest, and 27 days old, began to feed itself. In the Andes, dull juvenile *Tangara* and members of other highland genera remain with their parents for a few weeks to, possibly, several months, and are frequently seen accompanying the adults to fruiting trees and foraging with them in mixed-species flocks. The age at which tanagers first breed is unknown, but it is likely to be at about one year old.

The breeding behaviour of genera traditionally placed in Thraupidae, but found in recent studies to be genetically closer to other families (see Systematics), is worthy of examination. The genera concerned are *Euphonia*, *Chlorophonia*, *Chlorospingus*, *Mitrospingus*, *Rhodinocichla*, *Piranga*, *Habia*, *Chlorothraupis*, *Spindalis* and *Calyptophilus*. Many aspects of the breeding behaviour of these genera resemble those of the true tanagers. Differences are most pronounced in *Chlorophonia* and *Euphonia*, all members of which construct well-made, enclosed, globular nests with a small entrance on the side. *Chlorophonia* species build nests in branch forks or crevices, usually well above ground, but occasionally in vegetation on a steep bank. *Euphonia* species nest at almost any height from ground level on road cuttings to the canopy of some of the tallest trees. Their nests are typically well hidden, wedged into crevices, tucked into moss beneath limbs, amid epiphytes and vines on the sides of trunks or large limbs, or occasionally in holes in posts. The Blue-hooded Euphonia (*Euphonia elegantissima*), Golden-rumped Euphonia, Thick-billed Euphonia and Yellow-throated Euphonia also frequently utilize mossy and vegetation-covered roadside banks as nesting sites. Such sites on steep banks are invariably well up on the side of the bank or on the top of it and represent, in a sense, elevated nesting sites. No member of either genus is a true ground-nesting species. A few euphonias are known to usurp old nests of other birds, especially of tyrant-flycatchers. The Thick-billed, Violaceous and Golden-sided Euphonias (*Euphonia cayennensis*) have all been documented using nests of other birds on multiple occasions, refurbishing these for their own purposes.

The White-lored Euphonia, an Amazonian forest-canopy species, regularly nests 30–35 m above ground, and is one of the few small oscine passerines to nest so high on a regular basis. During the early hours of the morning, both members of a pair regularly bring fibrous material for their nests, which are hidden in recesses in clumps of epiphytes, especially on the sides of large branches of emergent kapok trees. Both sexes of *Chlorophonia* and *Euphonia* participate in building the nest, but only the female incubates. So far as is known, females of both genera lay clutches of four eggs, less often three; this is almost twice that of small tropical passerines that build cup-nests. The incubation period is comparatively long, at 17–18 days. In Costa Rica, a female White-vented Euphonia covered the eggs for about 65% of the day. The young, which are almost completely naked on hatching, are fed by both adults, which often arrive together to feed them, although only one parent at time approaches the nest, the male usually taking the first turn. Nestlings are fed mainly with fruit pulp, regurgitated by the adult. The low-protein diet results in slow maturation compared with that of true tanagers. The chicks of both *Chlorophonia* and *Euphonia* typically are not feathered until they are about 15 days of age or more. After hatching, the nestlings of a female White-vented Euphonia were brooded at night only for about the first week; thereafter, they were left alone at night, despite their lack of feather development.

Young euphonias leave the nest at between about 17 and 24 days of age. Those of chlorophonias, which are fed almost entirely with fruit, leave at up to 23–24 days. In Costa Rica, Skutch noted that even at 11 days, an age at which most tanagers were feathered and nearly ready to fly, the young White-vented Euphonias were still nearly naked. Feathers on the back and wings began to expand when they were about 13 days old, and at 15 days most of their upper surface, except the head, was covered with feathers.

In their breeding behaviour, *Piranga*, *Mitrospingus*, *Chlorospingus* and *Habia* do not differ greatly from most true thraupids. Members of the genera *Piranga* and *Habia* build rather frail, poorly constructed nests, and the best-known *Chlorospingus* species, the Common Bush-tanager, builds large bulky nests of moss, ferns, dry grass and dead-leaf fragments and, like *Chloro-*

*The **Golden-browed Chlorophonia** perches below the side entrance of its globular nest to feed its downward-leaning young. The young are fed with regurgitated fruit pulp, which the adult produces with an upward and forward movement of the head, accompanied by a gape. The adults regurgitate several batches at each visit, enabling them to feed more than one chick, and sometimes all of them. With this low-protein diet, the nestling period is extremely long for such a small passerine, at 23–25 days. These chlorophonias may begin raising a second brood within two weeks of fledging the first.*

[*Chlorophonia callophrys*, Monteverde Forest Reserve, Costa Rica. Photo: Michael & Patricia Fogden]

phonia and *Euphonia*, occasionally nests at ground level on a steep bank. *Habia*, containing the ant-tanagers, appears to be the only genus for which even a weak distraction display is reported. Willis reported an example of bigamy by the Red-throated Ant-tanager, a male of which mated with two females, these then laying eggs in separate nests. Interestingly, Skutch also reported a case of bigamy by a true thraupid, the Blue-grey Tanager, in which two females laid a total of four eggs in the same nest, and both females incubated and fed the young. In this example, the dominant female assumed a much larger role in all nesting activities, spent more time in incubating, and also brought more food to the nestlings; the single male accompanying these two females followed each one sequentially during incubation, and more often accompanied the dominant female when feeding the young.

Nest helpers have been documented for the Red-throated Ant-tanager in Belize. The helpers were dull-coloured and presumed offspring of a previous generation. In the case of *Mitrospingus*, Skutch found that four or possibly five Dusky-faced Tanager adults fed the same young, and the food items apparently consisted only of insects.

*Observations suggest that the adult **Palm Tanager** feeds the nestlings at least partly by regurgitation. Palm Tanagers often raise multiple broods; in Trinidad, where they nest in all months, pairs have been known to breed four times in a year, with intervals of 1·5–6 weeks between broods. Palm Tanager nests are sometimes parasitized by Shiny Cowbirds* (Molothrus bonariensis). *In one nest in Brazil, two cowbirds and one Palm Tanager hatched; after twelve days one cowbird was left, weighing 33 g. Palm Tanagers have also been seen to feed fledgling cowbirds.*

[*Thraupis palmarum atripennis*, Anorí, Colombia. Photo: Joe Tobias]

*Both **Palm Tanager** parents may be present on the nest at the same time, the later arrival waiting for the first to finish. Nest helpers, presumably the young of the previous season, have been observed to feed nestlings in some species of* Tangara, Habia *and* Mitrospingus, *but not in* Thraupis. *In Costa Rica, however, one male and two female Blue-grey Tanagers* (Thraupis episcopus) *attended a nest with four eggs. Both females incubated and all three adults fed the young.*

Few long-term studies have been conducted on the longevity and site-fidelity of tanagers. The mark-recapture work by the Snows from 1957 to 1961, and later by A. Lill from 1967 to 1971, at about 150 m elevation on the island of Trinidad provides an important published source of information on these aspects with regard to wild-trapped tanagers. While the exact age at the time of first capture was known for only a few birds ringed as juveniles, minimum ages were calculated to the nearest 0·5 years and included the following: one Bay-headed Tanager 5 years old; one Blue-grey Tanager 7 years old; one Palm Tanager 9 years old; and two Silver-beaked Tanagers, one at least 8 years of age and the other exactly 9·5 years old. Furthermore, the first three species were recaptured at the sites where they had first been caught, providing evidence of remarkable site-fidelity. The two Silver-beaked Tanagers were recaptured about 700–800 m and 200–300 m from their original capture sites. Sight records of a ringed White-lined Tanager indicated an age of at least 6–7 years. These data clearly indicate that the species concerned are capable of reaching a considerable age in Trinidad. The highest (minimum) ages at latest recapture ranged from 5 to 11 years for 19 individuals of 13 other species of mostly small insectivorous and omnivorous bird in Trinidad, and these figures are probably representative of many small Neotropical passerines. From a much larger sample of White-bearded Manakin (*Manacus manacus*) recaptures at the same sites as those where the tanagers were ringed, Snow and Lill estimated an annual survival rate of 79–89%, the higher figure believed to represent the more accurate rate. A similar rate may apply to many small Neotropical species, including tanagers, living in forest and forest edge.

A larger data set, comprising some 8500 ringing records, was compiled by H. Loftin from several sites in Panama between 1962 and 1974. For the Silver-throated Tanager Loftin reported eight longevity records, ranging from a minimum age of 2 years 8 months to a maximum of 7 years 6 months. This last individual, from near Cerro Punta, was also caught at least four times between the first and last dates of its capture, always at the same locality. The oldest ringed tanager recovered was a Blue-grey Tanager, found dead 9·5 years after it had first been ringed and less than 1 km from the original ringing site. Other longevity records included a Palm Tanager with a minimum age of 3 years 1 month, five Crimson-backed Tanagers ranging in age from 2 years to 3 years 1 month, a Rosy Thrush-tanager 2 years and 1 month old, and two Common Bush-tanagers with respective ages of 3 years 10 months and 3 years 8 months. In addition, T. C. Crebbs reported three ring returns of Plain-colored Tanagers on Barro Colorado, in central Panama, all more than 6 years after ringing.

A team of researchers working from 1994 to 2004 on Guana Island, in the British Virgin Islands, reported longevity records for migrant and resident birds. The data include a ringed Bananaquit which, when recaptured, was known to be at least 7 years old.

Movements

Any discussion of the movements of a group of birds as complex as the Thraupidae, regardless of the taxonomic boundaries of the family, risks oversimplification. Movements made by members of the family range from essentially none, with species resident on permanent or semi-permanent territories for all or almost all of their adult lives, to minor local shifts in populations, and to significant seasonal south–north migratory movements undertaken by several species that occur in Argentina, Paraguay and southern Brazil. Local movements may involve distances of less than 1 km or of a few tens of kilometres, and include relatively small numbers of individuals. Longer movements can involve all or a significant proportion of an entire population. In addition, movements include elevational shifts on a periodic or regular basis, when all or portions of a population move various distances up or down mountain slopes. Post-breeding dispersal involves yet another type of movement, one that is likely common among tanagers, although poorly documented. There is some recent evidence that a few southerly tanagers may wander widely after breeding, even appearing in areas south of where they breed. Such movements as these may be the result of human-altered environments and new food resources, but the phenomenon has received little attention from ornithologists.

In broadest terms, most tanagers appear to be sedentary, remaining resident throughout their lives in one place or keeping to relatively small home ranges once pairs are established. This statement, however, masks the patterns of an unknown number of species in which short-distance or seasonal movements, or both, are superimposed on the presence of residents. Dynamic and complex population movements of this sort are difficult to

After 20 days, the young ***Sayaca Tanager*** *is ready to leave the nest, though the juveniles remain with their parents during the non-breeding season. They may first breed while still in immature plumage. Nest-sites of this species are usually concealed in thick foliage. Almost all the records of the Sayaca Tanager in Buenos Aires province are from the austral winter months, suggesting a southward post-breeding dispersal by adults or juveniles. Like several* Thraupis *species, the Sayaca Tanager thrives near human settlements and may be increasing its range.*

[*Thraupis sayaca sayaca*, Minas Gerais, Brazil. Photo: Anita Studer]

detect and monitor, and they have been documented for only a few species. Most tanagers have not been studied in any detail, and the majority of the long-term work that has been done involves only a few sites.

While many, perhaps most, species of tanager found in lowland and montane humid forest are relatively sedentary, local seasonal movements do occur, and even populations of sedentary species may shift locally with varying food abundance. Species dependent upon fruit and nectar, in particular, are prone to seasonal and sometimes unpredictable movements. Away from zones of humid tropical forest, as, for example, in lower Central America, the Amazon Basin and the Andes, however, a rather different picture emerges. Among tanagers occurring in areas where environments are more seasonal, or more open, or experience strong dry seasons, there appears to be an increase in the proportion of species that undertake seasonal movements. The pattern is similar in marginal habitats, such as tree-line ecotones, which are prone to extremes of temperature and rainfall and intense fogginess, and in areas outside tropical latitudes where seasonal environmental factors limit resources and favour migratory responses. Thus, the movements that are evident in this family are related in various ways to the habitat and geographical region in which the species occur.

Long-distance migration is undertaken by relatively few species of tanager. The most frequently cited examples are the four species of *Piranga* in North America, but all four have recently been shown to be genetically closer to cardinalids than to thraupids (see Systematics). One of these, the Scarlet Tanager, and the eastern population of another, the Summer Tanager, are intercontinental migrants that migrate seasonally between non-breeding areas in northern South America and Amazonia and breeding areas in North America. The two western breeding species, namely the Northern Hepatic-tanager and the Western Tanager, as well as the western breeding populations of the Summer Tanager, move primarily between non-breeding areas in Mexico and Central America and their breeding areas in northern Mexico and the USA. With the removal of this group, the phenomenon of long-distance migration, movements of more than 1000 km, may be confined among tanagers to, at best, only a few austral species. This is true even with the inclusion of many species currently placed with the emberizids but recently found to be genetically closer to thraupids. Migration into and out of the southern cone of South America is similar to that in North America, but the distances travelled are smaller and the movements less dramatic, because fewer birds are involved. In the extreme south, in Tierra del Fuego, about 50% of all landbirds are migratory, and these migrants are almost entirely flycatchers that depend upon insects for food. No tanager in the present classification occurs so far south. The Blue-and-yellow Tanager, the most southerly one, breeds as far south as Río Negro Province, in Argentina, but it withdraws from these southernmost areas during the austral winter. It is not known where the bulk of these migratory individuals go, but the species is regarded as "more common" around Buenos Aires in the winter months of approximately April through September, suggesting that migratory movements by this species are, at best, moderate and may involve relatively small distances and perhaps only portions of the population. The southernmost populations of the Rust-and-yellow Tanager (*Thlypopsis ruficeps*), those occurring in the vicinity of Tucumán, in northern Argentina, have been reported as moving northwards along the slopes of the Andes during the coldest months, as has the congeneric Orange-headed Tanager, which occurs in the lowlands of Tucumán, although the extent and duration of these movements are not well documented.

In south-central and south-eastern Brazil, tanagers that undertake small seasonal migratory movements are predominantly species of light woodland or dry, semi-open habitats, and their movements may be northward during the coolest austral winter months or, in some cases, may involve elevational shifts. Among those mentioned by Sick and others are the Brown Tanager (*Orchesticus abeillei*), part of the population of which may be migratory; the Cinnamon Tanager (*Schistochlamys ruficapillus*) and the Black-faced Tanager, both of which may move away from parts of their range seasonally; the White-banded Tanager, which may exhibit some migratory and local movements in south-central Mato Grosso; the Orange-headed Tanager, for which seasonal movements have been noted in Mato Grosso; the Ruby-crowned Tanager, which shows seasonal fluctuations in numbers in the former Brazilian state of Guanabana, around Rio de Janeiro; and the Lowland Hepatic-tanager, which is reported as migrating northwards out of southern Brazil when not breeding, although recent observations by Argentinian observers suggest that the reverse may occur in Argentina (see below). Among other southeast Brazilian species that show some seasonal migratory

It has been suggested that, when tanager nestlings are newly hatched, the adults consume their faecal sacs but that, as they get older, their parents carry the sacs away, as this ***Orange-headed Tanager*** *is doing. Studies of the Beryl-spangled Tanager* (Tangara nigroviridis), *however, found that adults consumed a small proportion (13·6%) of all the faecal sacs produced, with no discernible trend as the nestlings grew. What changed was the number of faecal sacs produced in the presence of the adults: 100% in the first days, falling to 20% by the day of fledging.*

[*Thlypopsis sordida sordida*, Alagoas, Brazil. Photo: Anita Studer]

movements, including elevational shifts, are the Azure-shouldered Tanager (*Thraupis cyanoptera*), Golden-chevroned Tanager, Blue-and-yellow Tanager, Brassy-breasted Tanager, Burnished-buff Tanager, Black-backed Tanager, Chestnut-backed Tanager, and Black-legged Dacnis (*Dacnis nigripes*), the last being apparently absent from parts of its small range in Rio de Janeiro during the April–August winter months.

Willis, in a summary of landbird migration in São Paulo, in south-east Brazil, provides some perspective on southern-latitude bird migration. He estimated that in the state of São Paulo about 24% of all landbirds, which totalled some 584 species, were known to migrate or wander seasonally. About 60 moved northwards during the coldest months, twelve of these being North American breeders, and ten species arrived from the south. The percentage of migrants increased to the south, reaching 33% in Paraguay and 35% in the north-central Argentinian province of Córdoba. These figures are smaller than those at comparable latitudes in North America, but larger than may be generally realized. Unsurprisingly, species that depend upon flying insects were the most highly migratory, while frugivores were mostly local migrants and some omnivorous species exhibited local movements. Bananaquits, as well as hummingbirds, sometimes showed local and altitudinal movements, but the sum of their movements was near zero, departing species often being replaced by arriving species with different bill and body sizes that were better able to exploit the existing resources at that time of the year. Seed-eating emberizids, most of them now believed to be tanagers (see Systematics), were highly migratory, two southern species, four breeders and seven wandering species all exhibiting movements. Most frugivorous/insectivorous species, including ten Thraupidae, were primarily elevational migrants, descending to coastal areas during the winter months, these populations then returning to higher altitudes to breed. Although these elevational movements have been little studied by scientists, they are well known to cagebird-trappers. Willis notes that altitudinal movements are particularly difficult to verify because they often do not involve entire populations but, instead, migrants overlap with resident individuals in various ways. For example, some individuals may stay, rather than migrate, making this a partial migration, or individuals may migrate into the ranges of the residents at various sites, an "overlap migration".

With regard to Paraguay, F. E. Hayes and others describe two kinds of migration. The first, involving what they called "northern austral migrants", consisted of birds that breed in Paraguay and migrate northwards during the austral winter. The second, by "southern austral migrants", consisted of birds that breed primarily south of Paraguay and migrate north into or beyond Paraguay during the austral winter. These patterns provide a broad view of seasonal bird movements in Paraguay, but they mask more complex patterns, such as species for which both types of migratory movement occur at the same time, as well as a few species that are primarily or entirely transients through Paraguay. Hayes regarded the Swallow Tanager as a rare northern austral migrant. Although the number of records is small, the species is a rare non-breeding migrant in the Chaco, in west Paraguay, and is an uncommon breeder only in the eastern part of the country. A single July record in western Paraguay, during the heart of the austral winter, could represent one of several possible scenarios: a southerly breeder moving north, a Paraguay breeder that failed to migrate, a wandering individual, or an early-returning migrant. Among the group of birds regarded by Hayes and colleagues as southern austral migrants, only two are tanagers, these being the Lowland Hepatic-tanager and the Blue-and-yellow Tanager. The Lowland Hepatic-tanager is a rare to uncommon breeder in Paraguay, but its small breeding population is swamped by an influx of individuals that breed to the south and move varying distances northwards during the coolest months. For example, 61% of the Lowland Hepatic-tanager records fell between May and August, while only 15% of all records were between November and February. Blue-and-yellow Tanagers occur primarily as migrants into and through Paraguay, most records falling between the end of March and early October. Significantly, six species currently placed in Emberizidae but now thought, on the basis of molecular-genetic studies, to be closest to tanagers, are austral migrants to Paraguay, namely the Black-crested Finch (*Lophospingus pusillus*), Black-and-rufous Warbling-finch (*Poospiza nigrorufa*), Ringed Warbling-finch (*Poospiza torquata*), Grassland Yellow-finch (*Sicalis luteola*), Marsh Seedeater (*Sporophila palustris*) and Chestnut Seedeater (*Sporophila cinnamomea*). Most are rare or irruptive migrants in Paraguay from more southerly breeding sites, but their presence, and possibly that of others, points to a relatively widespread pattern of northward movement out of

Brood parasitism by Shiny Cowbirds (Molothrus bonariensis) *has been reported as affecting the* ***Bicolored Conebill*** *in Suriname and Trinidad, and is here shown in Brazil. Black-faced Tanagers* (Schistochlamys melanopis) *are reported as being frequently parasitized by Shiny Cowbirds in Brazil, and some* Thraupis *species are frequent victims, particularly in Trinidad, where the cowbirds are recent arrivals and the hosts consequently naive. Forest fragmentation may be exposing some species previously immune: Scarlet Tanager* (Piranga olivacea) *populations are in decline, and cowbird parasitism may be a factor.*

[*Conirostrum bicolor bicolor*, Mangroves of Santos, São Paulo, Brazil. Photo: Robson Silva e Silva]

southern latitudes by small nine-primaried oscines during the austral winter.

Although it has been noted that tanagers migrate northwards out of higher austral latitudes during the southern winter months, these movements may be more complicated than simple northward travel. While the Swallow Tanager, a common breeder in north-east Argentina, mostly migrates north after breeding and is regarded as scarce and hard to find during the winter months, the opposite may be true for some species. In their evaluation of the distribution of birds in Buenos Aires province of Argentina, T. Narosky and A. Di Giacomo note that, while some tanager populations are mobile during the cooler non-breeding season, from approximately March or April to October, a wholesale exodus of tanagers during the winter months, as made by many bird species in North America, does not occur. On the contrary, the populations of some species may simply undertake local reposi-

Beginning with the publication of a catalogue of eggs in 1899, a series of otherwise authoritative books claimed that the ***Red-legged Honeycreeper*** *laid black eggs and built a pensile "bag" nest, hanging from a branch over water. The nest had already (1857) been correctly described as the kind of open cup containing whitish, speckled eggs that is typical of almost all thraupids. Both sexes of Red-legged Honeycreeper feed the young, bringing mostly fruit, with some insects, but the male's contribution is irregular. The nestling period is 14 days, but in one case in Brazil the interval between nest completion and fledging was just 22 days.*

[*Cyanerpes cyaneus carneipes*, Panama. Photo: Kathy Kinnie]

Many, if not most, tanager species have a distinct juvenile plumage, but the newly fledged ***Magpie Tanager*** *is barely distinguishable from the adult. Once fledged, the period for which young tanagers remain dependent on their parents varies among species. Young Bananaquits* (Coereba flaveola) *are said to leave their parents almost immediately, while Blue-necked Tanagers* (Tangara cyanicollis) *are independent within three weeks and Silver-throated Tanagers* (T. icterocephala) *continue to be fed for more than a month. The young may remain with their parents well beyond the period of dependency, and in some species may contribute as helpers in the next breeding season.*

tioning, rather than long-distance migration, after the breeding season. For example, the Diademed Tanager of south-east Brazil and north-east Argentina undertakes a generalized post-breeding dispersal out of the coastal *Celtis* woodlands and gallery and riverine forests where it breeds in Argentina, and moves into a wider range of habitats than those in which it breeds, but the population as a whole does not make a northward migration. Observations by Argentinian observers G. Pugnali, K. Roesler and H. Casañas suggest that the abundance of some tanagers around Buenos Aires and Córdoba changes seasonally, but not in the way one might expect. Several species that breed to the north of Buenos Aires are commoner and more widespread around Buenos Aires during the cooler winter months, a pattern suggesting a southward post-breeding dispersal by adults or juveniles. For example, almost all of the records of Sayaca and Guira Tanagers in Buenos Aires province and of Orange-headed Tanagers in Entre

The ***Black-chinned Mountain-tanager*** *is a restricted-range species, found in a rather narrow elevational band of Pacific-slope montane forest (the Chocó Endemic Bird Area) in Colombia and Ecuador. Deforestation, farming and illegal cultivation of coca and marijuana are ongoing threats, and this species, though not yet regarded as globally threatened, is almost certainly declining. It is found in a number of protected areas in both countries. It is sometimes found together with the similar Blue-winged Mountain-tanager* (Anisognathus somptuosus), *which favours forest edges for breeding, while the Black-chinned Mountain-tanager needs undisturbed, epiphyte-laden forest.*

[*Anisognathus notabilis*,
Mindo Loma Cloud Forest Reserve, Pichincha, Ecuador.

Rios province are of birds present during the austral winter months. Similarly, the Chestnut-backed Tanager, a species that occurs in semi-open habitats from south of Brasília and Goiânia southwards to Buenos Aires, moves around seasonally, and there are more records of this species in the southern part of its range in the winter months than at other times of the year. A similar pattern may occur with the Lowland Hepatic-tanager, which is a widespread breeder in northern and north-western Argentina but is, during the post-breeding winter months, more numerous in the southern parts of its range, around Buenos Aires. The Fawn-breasted Tanager is another species which exhibits a significant post-breeding dispersal southwards during the winter months. Di Giacomo has noted that Fawn-breasted Tanagers could be coming from the Atlantic Forests of Brazil, some moving as far south as Buenos Aires province during the winter months, although he cautions that much remains to be learnt about the post-breeding movements of these and others tanagers. The possible influence of human-altered environments, such as planted ornamental or non-native fruiting trees and shrubs, accompanied by increased insect infestations of non-native plants, which may lead to more exploitable food resources, looms as one possible cause of these curious movements, but the topic remains unstudied.

Away from austral latitudes, migratory movements have been reported for relatively few tanagers. The Black-and-white Tanager is unusual in that it breeds in arid regions of western Ecuador. It is one of the few tanagers to utilize an arid habitat, but it does so only when periodic rainfall creates a flush of vegetative growth and insects, and breeding times are consequently variable and unpredictable from year to year. Outside the breeding period this tanager is possibly nomadic, or there may be a regular trans-Andean migration into Amazonia, but movements of the species are poorly understood. The Flame-colored Tanager of the mountains of Mexico south to western Panama moves to lower elevations seasonally. Also, the Plain-colored Tanager's seasonal fluctuations in numbers in central Panama are well documented. The Yellow-collared Chlorophonia (*Chlorophonia flavirostris*), although now generally placed with the Fringillidae, is unusual in that its distribution in western Colombia and north-western Ecuador coincides with one of the wettest and least seasonal regions in the Western Hemisphere, yet this species, when not breeding, wanders widely, apparently in search of suitable fruiting trees with small berries. In Colombia, single-species flocks of 30 to over 80 individuals have been repeatedly seen at fruiting *Miconia* trees at various times of the year in the department of Valle del Cauca, both in the lowlands and in the foothills up to an elevation of 1050 m. Even larger flocks, estimated to contain up to 150 individuals, have been observed in western Ecuador. These large monospecific flocks associate incidentally with mixed-species flocks at fruiting trees, especially *Miconia*, but otherwise move largely independently of them and have been seen to fly high over foothill-forest canopy and move long distances across deep valleys and along steep, forested slopes.

The seasonal elevational movements of the Scarlet-thighed Dacnis (*Dacnis venusta*) are well known in lower Central America. This species breeds in the mountains, usually above 500 m, and on the Pacific slope above 900 m, but wanders to sea-level in search of fruiting trees when it is not breeding. In western Colombia the post-breeding pattern may be similar, although the species is most numerous at somewhat lower elevations and post-breeding dispersal may involve movements both to higher and to lower elevations. For example, during a 15-month period of intensive observation at an elevation of 1050 m in the Anchicayá Valley, Hilty noted the species only in December, but for a short period of time several were present. Local seasonal movements have been reported also for the Blue Dacnis in Brazil. Some *Cyanerpes* honeycreepers are known to migrate away at the conclusion of breeding, but their dramatic and sometimes puzzling arrivals and departures, especially those of the Red-legged Honeycreeper, as well as their ultimate destinations, are poorly understood. Nectar-eating birds are notoriously sensitive to changes in resource levels, and this is perhaps best illustrated with hummingbirds, the populations of which can appear or disappear overnight in response to flower abundance. Similarly, many flowerpiercers rely heavily on nectar and their populations are sensitive to flower abundance and the nectar contained therein. Some, such as the Cinnamon-bellied Flowerpiercer of Middle America, are reported as moving up or down mountain slopes, presumably in response to nectar abundance. Some Andean flowerpiercers, especially high-elevation "black" species with a smaller and more strongly hooked bill, are intensely territorial, the males and females holding separate feeding territories, and engaging in fiercely competitive interactions with other

*The **Emerald Tanager** is a restricted-range species, patchily distributed across an area of about 38,500 km². It is fairly common in Costa Rica and Colombia, but more local in Panama. There is still extensive humid forest along the foothills and lower slopes of the mountains of its range, but most is unprotected, and cattle-ranching, gold-mining and legal and illegal crops are all encroaching. When foraging for arthropods, the Emerald Tanager is a mossy-branch specialist and favours primary forest, though it is also found in adjacent older second growth. The population is suspected to be declining, but does not approach the threshold for listing as globally threatened.*

[*Tangara florida*, Río Canandé Reserve, Esmeraldas, Ecuador. Photo: Doug Wechsler/ VIREO]

The lower slopes of the tepuis of southern Venezuela, Guyana and northern Brazil consist of rock debris fallen from above. They are covered in tropical and subtropical forest, which is kept wet by the clouds that form around the cliffs overhead. Because they are so inaccessible, there has so far been relatively little human impact, and the high number of endemic and restricted-range species found on and around them, including the ***Olive-backed Tanager****, are mostly considered stable and of Least Concern. Much of the Olive-backed Tanager's range is covered by the Canaima National Park, in Venezuela.*

[*Mitrospingus oleagineus obscuripectus*, La Escalera, Bolívar, Venezuela. Photo: Andrew Moon]

flowerpiercers and other competitors, such as hummingbirds and conebills. Larger "blue" flowerpiercers, and others with a longer, thinner bill and a less strongly hooked bill, supplement their diets with many kinds of small fruit and even flying insects, and are less dependent upon nectar resources. These species are markedly less territorial, they regularly travel with mixed-species flocks, and their seasonal numbers are likely to reflect the abundance more of fruit resources than of nectar. The extent to which flowerpiercers, large or small, move seasonally or engage in vertical migrations up and down mountain slopes remains unknown. Small movements do occur as populations adjust locally to shifting nectar resources, but larger-scale movements are poorly documented. In Venezuela, Hilty observed a flock of approximately 25 Masked Flowerpiercers, a species that includes more fruit than nectar in its diet, as it moved rapidly upslope in the Mérida Andes, this being one of the few reports of a mass elevational migration by a flowerpiercer.

The small size of many islands in the Caribbean may limit opportunities for anything but local movements unless a species leaves an island. The four species of *Spindalis*, as currently recognized, are well known for seasonal movements within their own island or island group, including, respectively, the Bahamas and Cuba, Jamaica, Puerto Rico, and Hispaniola. The Western Spindalis was formerly reported in large flocks on Cuba, and birds from the Bahamas occasionally wander to Florida, on the USA mainland, suggesting that significant periodic or irruptive inter-island movements occur.

Despite the fact that many tanagers are widespread, and common and easy to observe, there are few published studies of the daily or seasonal movements of tanagers, or of the stability of pair-bonds. Most of what has been published in this regard comes from the meticulous observations of Skutch in Costa Rica, but Skutch did not individually mark birds, a fact that prevents the obtaining of long-term information. He did attempt, with very limited success, to mark a few birds individually with wet paint placed on nest rims, but his comments on seasonal or longer-term movements and pair-bond stability of members of the family are limited to generalized comments.

Some insight into population stability in a community of tanagers can be gleaned from a study in Colombia. During 15 months of intensive observation Hilty, working on Colombia's Chocó–Pacific slope, colour-marked 330 tanagers of 17 species. This population was resampled two years later, when ten individuals of eight species were located again. One Yellow-throated Bush-tanager was present for the full 3 years and 1 month, and was located less than 50 m from its original capture site. A second individual with a minimum age of 2 years 8 months was less than 200 m from its original capture site. Other species present for a minimum of 3 years and 1 month included a Palm Tanager, a Blue-necked Tanager and an Orange-bellied Euphonia; the Palm Tanager was found less than 200 m from its original capture site, and the other two were less than 50 m from their original sites. Other species present on the site for more than 2 years included a Rufous-throated Tanager, present for 2 years 3 months; a Blue-necked Tanager, for 2 years 2 months; a female Scarlet-and-white Tanager, for at least 2 years 8 months; and a Bananaquit, present for 2 years 8 months. A ringed female Bay-headed Tanager was mated with a ringed male when captured near the outset of the study, but it was with an unringed male 2 years and 10 months later. No individuals ringed as juveniles or immatures were recaptured or seen more than a few months later. Consequently, the ages of the marked adults cannot be determined, but the recaptures and sightings of the colour-ringed birds provide minimum ages and some insight into population stability in this community of tanagers. These records, although limited in duration, suggest that at least some adult tanagers in this community are quite sedentary.

This Colombian Chocó–Pacific site, at 950–1050 m in the Anchicayá Valley, experienced high annual rainfall, with minor peaks in March-April and September–December. A corresponding small, bimodal peak in fruit abundance was evident. In this relatively non-seasonal environment, tanager populations were fairly stable. Net capture-recaptures and transect counts revealed almost constant numbers of species and individuals present throughout the initial 15-month study, although there was considerable population turnover, especially among immatures, which were seldom recaptured. Average foraging distances expanded somewhat during periods of reduced fruit availability, in July–August, and contracted during a November–December peak. Thirteen additional non-breeding species from higher or lower elevations were also recorded; eleven of these were present for less than 1–3 months, and the other two for up to 6 months. Seven were highland breeders dispersing downslope, and six were lowland breeders dispersing upslope. These elevational upslope and downslope migrations accounted for 13 of 41 species of tanager

*The **Scarlet-thighed Dacnis** appears always to have been patchily distributed and uncommon, or seasonally common, over most of its 201,000 km² range. Outside the breeding season, it disperses in search of fruiting trees and shrubs, appearing both on Colombia's coastal plain and in smaller numbers at up to 1100 m. It is not currently regarded as threatened, but deforestation in the lowlands and foothills of lower Central America is extensive and ongoing. In western Ecuador, loss of lowland forest outside protected areas is approaching 100%. The Scarlet-thighed Dacnis is found in a number of protected areas.*

[*Dacnis venusta fuliginata*, Río Canandé Reserve, Esmeraldas, Ecuador. Photo: Doug Wechsler/ VIREO]

recorded at the site. There was only a single elevational migrant present during the period August–October. The greatest number of highland species recorded simultaneously was three, in November, March and May; for lowland species moving upslope, a maximum of three was recorded in April and June. Overall, slightly more upslope and downslope movement of tanagers in the Anchicayá site occurred during the months of November and January–June. These data provide a snapshot of seasonal movements over an annual cycle, but a fuller picture can be gained only with longer-term observations. What emerges from study in Costa Rica, and this study in Colombia, is that these avian communities are dynamic, the species constantly adjusting to changing resource levels, and non-breeding individuals, as well as immatures, or "floaters" in populations, contributing to a continuous population turnover. Thus, broad generalizations about seasonal population changes and movements are likely to obscure underlying complexity.

Mark-recapture details for the Ochre-breasted Tanager revealed that this species, now shown to be genetically unrelated to thraupids (see Systematics), regularly ranged over larger areas and exhibited greater mobility than any of the other 17 tanagers under observation. Eleven days after capture, one individual was sighted 700 m away, and marked individuals were routinely found 450–600 m from their respective capture sites. Colour-ringed Scarlet-and-white Tanagers also were evidently resident on the Colombian site, with four of six birds present for more than twelve months and 12 of 16 present for at least six months, but some local movements were complex and unexpected. For example, one family of this species, consisting of an adult pair and an immature, remained near its original capture site for eleven months, and then abruptly moved to a new area some 300 m distant and partly within the home range of a second family resident there for at least seven months. One male Scarlet-and-white Tanager was found, three months after capture, more than 850 m from its original site, the greatest distance for any small passerine in the study.

Although *Chlorophonia* and *Euphonia* are now thought to be closest to fringillids (see Systematics), the seasonal movements of these "former tanagers" are instructive. Members of both genera breed in pairs, but, when not breeding, most chlorophonias form small flocks that spend much of their time in eating mistletoe berries and sheltering inside large bushy clumps of canopy mistletoe. One exception within this genus is the Yellow-collared Chlorophonia, which forms large post-breeding flocks that may wander widely and feed extensively on small berries of *Miconia*, rather than mistletoe. Little is known about seasonal movements or pair-bonding of *Euphonia*, but colour-marked Orange-bellied Euphonias were followed for 15 months in the Anchicayá Valley of western Colombia and, of twelve individuals colour-ringed for a year or more, six were present at least 12 months later; 18 of 26 birds, about 69%, were present at least nine months after marking, and 36 of 42 birds, almost 86%, were observed at least

*There are four races of the restricted-range **Greater Flowerpiercer**, largely or entirely isolated from one another on the tepuis of south-eastern Venezuela, Guyana and northern Brazil. Although found as low as 1300 m, they become common to abundant only at higher elevation, for example, above 2000 m on Cerro Roraima in Brazil. Their total range is small, but there are few human settlements within it. The population appears to be declining because of habitat loss, but the species is not regarded as globally threatened. The Greater Flowerpiercer is found in Venezuela's Canaima National Park and in the Kaieteur National Park, in Guyana.*

[*Diglossa major major*, Sierra de Lema, Bolívar, Venezuela. Photo: David Southall]

three months after initial capture. No recaptures or resightings of any of 36 marked individuals were at more than 600 m from the original marking site. One marked adult male recorded 20 times during a 15-month period was never more than 200 m from his original capture site, and another male, recorded 31 times during a ten-month period, was never more than 250 m from where he had originally been captured. A marked female observed twelve times in 15 months was even more sedentary, never straying more than about 150 m from her original capture site. These data suggest that some small frugivores are highly sedentary in these Chocó–Pacific pre-montane wet forests, where abundant rainfall is distributed fairly uniformly throughout the year, and where no annually recurring periods of severe fruit-resource scarcity are evident. Orange-bellied Euphonias were almost always seen singly or in pairs and often with mixed-species flocks, but they did not gather in groups of their own.

Relationship with Man

Tanagers are widespread throughout the American tropics and extend, in decreasing numbers, somewhat beyond tropical latitudes. Being generally small, they are of little interest to native hunters as a source of food. Likewise, they are usually not serious pests of agricultural crops, although Blue-grey and Palm Tanagers, Silver-beaked Tanagers and a few other species may inflict minor damage locally to fruit crops such as bananas and papayas (*Carica papaya*) in gardens and small orchards. Although this activity does not endear them to humans, these birds do also eat many harmful insects. As some tanagers live in close association with human beings, their lives and fates are, for better or worse, often closely tied to those of humans, who almost constantly modify and reshape the environment, shoot at them with sling-shots, trap them for use as cagebirds, keep pets that may harass or kill them, and generally give little thought to the welfare of this colourful and engaging and sometimes songful group of birds.

The name "tanager" appears to have been derived from a Tupí-Indian word *tangará*, a local name used in Pernambuco, and perhaps elsewhere in eastern Brazil, for the Seven-colored Tanager. The original name survives today among some native cultures, but, at least in Brazil, various indigenous groups now more often use the word *tangará* to denote certain manakins, especially the *Chiroxiphia* species, and in parts of Amazonia local inhabitants apply it to the Red-capped Cardinal (*Paroaria gularis*). This same word, *tangará*, is used by other native groups in present-day Paraguay and adjacent areas for birds that are today referred to as "tanagers". The first mention of the word *tangará* in scientific writing is found in Marcgraf's treatise on plants and animals, written in 1648.

Over much of their geographical range, tanagers have had an important relationship with humans because so many species have colourful plumage and because a few of them also sing nicely. This relationship, unfortunately, has been detrimental to those species most highly sought for their brilliant plumage. As pointed out by Sick, the renowned German ornithologist domiciled in Brazil, tanagers have suffered in disproportionate numbers at the hands of native human populations, especially in the Amazonian region, where their bright feathers are valued for use in adornments. The brilliant, glistening feathers of the Masked Crimson Tanager, honeycreepers and others, along with those of parrots and macaws (Psittacidae), toucans and cotingas, have long been valued for their colours, and feature prominently in many handmade adornments. Among extant indigenous populations, these traditions continue today. The relatively small number of birds taken for these purposes, however, has likely had little overall effect on the populations of the tanagers most favoured. Unfortunately, this practice sometimes extends beyond local use. When indigenous communities have access to tourist markets, the brightly coloured feathers of many species of bird turn up as adornments on native products ranging from hand-made bows and arrows to combs, ear-rings and small purses, and these are eagerly purchased by national and international visitors.

Indigenous people have not been the only humans to admire the brilliant feathers and plumages of some tanagers. Following the colonization of South America by Europeans, the plumes and skins of many small, colourful tropical birds became objects of considerable economic value when, in the late 1700s and early 1800s, a growing European fashion industry began to incorporate plumes and even dried bird skins into ornaments for ladies' hats. At the peak of this fashion, hundreds of thousands of small colourful tropical birds, especially hummingbirds, tanagers, honeycreepers and cotingas, were killed by native hunters. The specimens, and feather samples, were shipped to Europe for resale to the growing plume market. These bright feathers became

*The **Blue-whiskered Tanager** is a restricted-range species and has been described as the least numerous of the Pacific lowland* Tangara *species. It is found at low densities from north Antioquia, in Colombia, south through north-west Ecuador to Los Ríos; in Colombia, however, it is common in several areas in Nariño. It may be present in other protected areas in Colombia and Ecuador, but there are few in its range. It is believed to be in decline because of the loss of its forest habitat in the Chocó–Pacific lowlands, and so it is considered Near-threatened. It is, however, able to use various stages of secondary forest habitats, including the regrowth around slashed clearings.*

[*Tangara johannae*, Playa del Almejal, Bahía Solano, Chocó, Colombia. Photo: Rodrigo Gaviria]

*The **Green-chinned Euphonia** is still thought to be fairly common in what remains of the Atlantic Forest of south-east Brazil, eastern Paraguay and north-east Argentina. It stays well up in tall trees, favouring epiphytic fruits and also appearing to depend on epiphytes for nest-sites. Although it occurs in numerous parks and reserves, it is assumed to have declined substantially with the loss of much of the Atlantic Forest, and it is considered Near-threatened. All unprotected forest left in its range is at high risk from a further range of threats, including settlement, industrial development and fragmentation by roads.*

[*Euphonia chalybea*, Volta Velha Special Reserve, Itapoá, Santa Catarina, Brazil. Photo: Edson Endrigo]

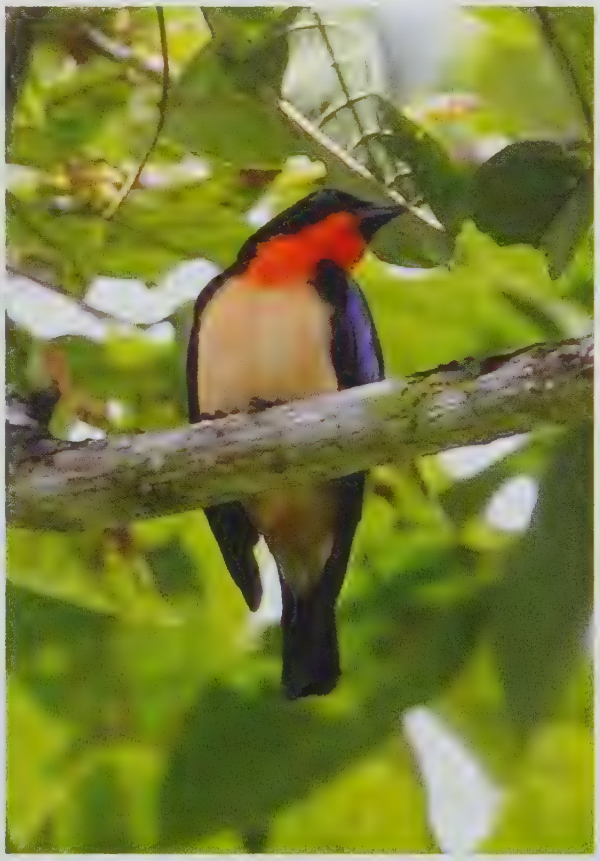
highly prized as fashion ornaments and contributed to an unfortunate and particularly destructive era of fashion. Ironically, it was from some of these large shipments of bird specimens arriving at European ports from northern South America that a few enterprising scientists, such as J. Gould, ultimately described many birds new to science.

Several tanagers figure importantly in the lives of humans because they have readily adapted to the changes that humans make in the environment. As a result, they are common residents around settled areas and familiar to almost everybody. One of these is the Blue-grey Tanager, widely known as *Azulejo* to Spanish speakers and as *Sanhaço da amazônia* in Brazil. Blue-grey Tanagers often use crannies in homes or other buildings for nesting sites, forage for fruit and insects in gardens, and are conspicuous almost wherever humans live. Their songs are energetic, though squeaky and unmusical, and the birds occasionally make a nuisance of themselves by damaging fruit, especially bananas and papayas, in orchards. Their ubiquitous presence in settled areas also places them at risk from mischievous young boys, who shoot at them with sling-shots. Several species of *Ramphocelus*

*A single-country endemic species, the **Sooty Ant-tanager** has a restricted range within northern Colombia, from the upper Sinú valley at the north end of the western Andes east to the middle Magdalena Valley. It was once believed to be approaching the threshold for listing as globally Vulnerable, but its range is now known to be larger than previously thought. It is found in Reserva El Paujíl and Reserva Bellavista, and is also present in scattered patches of unprotected forest, surviving locally in dense and surprisingly young second-growth scrub and palmetto. But because of the extensive destruction of suitable habitat, it is thought to be in moderately rapid decline and is listed as Near-threatened.*

[*Habia gutturalis*, La Victoria, Colombia. Photo: Ketil Knudsen]

Known from a small area on the northern and western slopes of the central Andes in Antioquia, in Colombia, the ***Black-and-gold Tanager*** *went unrecorded there for more than 50 years, until it was rediscovered in 1999 on the western side of the River Nechí. A second, discrete population is found on the Pacific slopes of the western Andes, on the Chocó–Risaralda–Valle del Cauca border. It is regarded as common in Tatamá National Park, in the western Andes, but this area has been severely deforested. The total population is fewer than 2500 and is almost certainly declining; the species is considered Vulnerable.*



[*Bangsia melanochlamys*, El Cairo, Valle del Cauca, Colombia.
Photo: Ketil Knudsen]

tanager also thrive in settled areas, and are well known to residents of rural areas and smaller villages. The name *pico de plata* is commonly applied to any of several species in this genus, among them the Silver-beaked Tanager and the Crimson-backed Tanager, because the males have a large whitish lower mandible which is conspicuous (see Morphological Aspects).

Less familiar to the public in general, but well known to biologists and naturalists, is the phenomenon of mixed-species flocks, which comprise an important component of avian ecosystems in both lowland and highland forests. While mixed flocks in lowland forests are apt to be composed of an array of species from many families, those in the highlands are often made up predominantly of tanagers. Moving restlessly through the canopy of misty cloudforest in the Andes and other mountainous areas, these fast-moving flocks typically include many tanagers with dazzling colours. On occasion, eight to ten species of colourful *Tangara* or allied thraupids may swarm around a small fruiting tree and, for a few moments, feed frantically, each bird moving and fluttering quickly in search of berries. It is an unforgettable sight, and a spectacle that has moved more than one observer to comment that the birds seemed like a swirl of colourful decorations on a Christmas tree. While birders and ecotourists may not undertake a foreign trip solely for the purpose of observing mixed-species flocks and feeding assemblages, such flocks are an important component contributing to the allure of highland regions in Middle and South America, and visitors to these places do provide a very real economic benefit to the local native communities.

Tanagers have endured a long and tragic relationship with humans in the form of the cagebird trade, both legal and illegal. It is, in large measure, due to their beautiful plumages and, to a lesser extent, because some have pleasing songs or are fairly accomplished mimics that they are so often pursued. Euphonias, probably better placed in Fringillidae (see Systematics), also are widely sought by trappers, as are seedeaters and various allied species mostly still placed with the emberizids but now believed to be closest to thraupids (see Systematics). In some areas, such as small Amazonian villages, bird-trapping is relatively insignificant and may involve little more than an occasional bird held in a crudely fashioned cage for personal pleasure. In areas where trappers have access to large city markets or to illegal international bird trade, on the other hand, the number of birds taken from the wild can have an impact on populations locally and then becomes a conservation issue. Bird-trapping as a conservation concern is discussed in greater detail below (see Status and Conservation).

Of all interactions between humans and tanagers, however, the most significant one, and the one affecting the greatest number

First described in 1964 in Peru, and more recently found in Ecuador, the ***Orange-throated Tanager*** *has a tiny global range of just 4200 km². It is present in the Andean Ridge-top Forests Endemic Bird Area, in mature humid forest, and in* terra firme *forest in adjacent lowlands. None of the land in its range is protected. It still appears common in suitable habitat in Peru. No estimates are available for Ecuador, but some authors believe it to be in serious trouble there because of deforestation, and it is considered Vulnerable. Much of its range lies in the territory of the indigenous Aguaruna tribe, who also report it from the headwaters of the River Nieva, some distance from its known range.*

[*Wetmorethraupis sterrhopteron*, Ecuador.
Photo: Terry S. Baltimore/ VIREO]

A restricted-range species, present in the Central Andean Páramo Endemic Bird Area, the ***Masked Mountain-tanager*** *has an estimated global population not exceeding 5000 individuals and is probably declining because of habitat loss. It is considered Vulnerable. The scattering of records from south-west Colombia, Ecuador and north-west Peru suggests that it is very localized. It is found at 2900–3650 m in low mossy forest, very humid elfin woodland, bamboo and giant grasses at or near the tree-line (the* páramo–*forest ecotone). But regular burning of* páramos *adjacent to elfin forest, to promote new shoots for livestock, has lowered the timber-line by several hundred metres.*

[*Buthraupis wetmorei*, Papallacta, Ecuador. Photo: Björn Anderson]

of tanagers, involves the loss of habitat through deforestation or habitat alteration. While a few species have benefited from human intervention in the landscape, far more have been adversely affected, a topic also discussed in the next section (see Status and Conservation).

Status and Conservation

Altogether some 283 species are included in the present treatment of Thraupidae. Recent molecular-genetic studies suggest that up to 20% of these species really belong in other families (see Systematics), whereas even more species currently in other families should ultimately be placed with the true tanagers in Thraupidae. Of the 283 tanagers in the family as presently constituted, 23 are considered to be threatened. Two, the Cherry-throated Tanager (*Nemosia rourei*) and the Cone-billed Tanager (*Conothraupis mesoleuca*), are listed as Critically Endangered. The historical distribution of the Cherry-throated Tanager may never have been large, while that of the Cone-billed Tanager is unknown. Today, the distributions of both species are alarmingly small.

The Cherry-throated Tanager was rediscovered in 1998, having not been definitely reported by anyone since 1941. Since its rediscovery, a concerted effort has been made by many observers to locate this species at additional sites, and it is now confirmed as being present at a minimum of three localities, and probably one or two more, but it occurs in very low numbers at all sites. Its world population is estimated to be, at best, a few hundred individuals, and perhaps as few as 50 birds. The south-eastern Atlantic Forests, where this species lives, are among the most severely deforested on the continent, and little pristine habitat remains outside parks and protected areas in south-eastern Brazil. Ironically, however, one site where the species has recently been found is on privately held land. Most forest tracts, whether private or public, are relatively small and isolated, and lack corridors connecting them to other forested sites, a situation which complicates the species' long-term survival prospects.

Similarly, the Cone-billed Tanager went undetected from 1938 until 2003, before being rediscovered in semi-deciduous gallery forest in Das Emas National Park, in the Brazilian state of Mato Grosso. This species remains one of the rarest and most poorly known passerines on the continent, and there still are only a handful of records from the park. The whereabouts of this enigmatic species have long been of interest, and at least one book has been devoted to documenting efforts to locate the species. Recently, it has been found at a second site nearly 900 km distant from the original location, but there is little information on its status in this new area, where at least 40 individuals were recorded at a total of 18 sites and the total population in this region is thought to number fewer than 100 individuals.

In addition to these two Critically Endangered species, six tanagers are classified as Endangered. These are the Gold-ringed Tanager, Golden-backed Mountain-tanager, Chestnut-bellied Flowerpiercer (*Diglossa gloriosissima*), Venezuelan Flowerpiercer (*Diglossa venezuelensis*), Azure-rumped Tanager and Black-cheeked Ant-tanager (*Habia atrimaxillaris*). Each of these species has a small historical range, less than 5000 km^2 or so, and the area of its occurrence within this historical range is believed to be declining. The ant-tanager, now shown to more closely related to Cardinalidae than to Thraupidae (see Systematics), is found only in portions of the humid Osa Peninsula lowlands of south-western Costa Rica; it is the only lowland species among the six classified as Endangered. The remaining five all are highly localized in montane sites, the Azure-rumped Tanager in humid montane forest in the foothills and slopes of extreme southern Mexico and adjacent Guatemala, the Venezuelan Flowerpiercer in humid and wet pre-montane forest in north-east Venezuela, the Chestnut-bellied Flowerpiercer near the tree-line in isolated sites in the western and central Andes of Colombia, the Gold-ringed Tanager in the western Andes of Colombia, and the Golden-backed Mountain-tanager in tree-line elfin woodland in the Andes of central Peru. Each of these species has a global range that is extremely small and lies only partly within protected areas. Each continues to suffer from loss of habitat outside protected areas, and from intermittent and unstable protection even within protected areas.

A further fifteen tanagers are listed as Vulnerable. Ten of these are found in the Andes, namely the Slaty-backed Hemispingus (*Hemispingus goeringi*), Rufous-browed Hemispingus, Black-and-gold Tanager (*Bangsia melanochlamys*), Masked Mountain-tanager, Multicolored Tanager (*Chlorochrysa nitidissima*),

The majority of tanager species currently considered to be at risk are from the Andes. This is because the greatest diversity of tanagers is in the Andes and many of these species have small and ecologically restricted ranges. The Chocó Endemic Bird Area alone holds 18 restricted-range species, including the ***Multicolored Tanager****, which is also found in the Colombian Inter-Andean Slopes Endemic Bird Area. A few large tracts of intact habitat remain within its range, but an expanding network of roads is opening up ever more remote areas to logging. Formerly common, the Multicolored Tanager is now recorded only infrequently and very locally. It is listed as Vulnerable.*

[*Chlorochrysa nitidissima*, Valle, Colombia. Photo: John S. Dunning/ VIREO]

Green-capped Tanager, Turquoise Dacnis (*Dacnis hartlaubi*), Scarlet-breasted Dacnis (*Dacnis berlepschi*), Tamarugo Conebill (*Conirostrum tamarugense*) and Yellow-green Bush-tanager. In each case, the species' population is small and/or fragmented and is elevationally restricted. These ten are scattered from Colombia south to southern Peru, and their populations tend to be heavily and adversely affected by deforestation or other human activities. With the exception of the Tamarugo Conebill of shrubby woodland, they are found in montane forest, which lies precisely within the zones that have been subject to much deforestation and alteration by rural people expanding their populations. Much of the land on which this expansion is occurring is steep, excessively humid, and largely unsuitable for subsistence agricultural practices. Of the remaining Vulnerable species, the Orange-throated Tanager occurs in the lowlands adjacent to the Andes, the Black-backed Tanager lives in montane Atlantic Forests of south-eastern Brazil, the Seven-colored Tanager is found in Atlantic lowland forests of Bahía, in east Brazil, and the last two constitute a Caribbean complex, the Eastern and Western Chat-tanagers, often regarded as conspecific.

The Seven-colored Tanager occurs in a number of protected areas, but is widely sought for the cagebird trade, suffers heavily from loss of habitat, and continues to be captured even inside protected areas, which often are not well patrolled. It may deserve to be accorded the status of Endangered. The heart of this species' range lies within the Atlantic Forests of north-east Brazil, and it is now estimated that less than 2% of the original forest remains in this area. The two chat-tanagers are restricted to Hispaniola. The Western Chat-tanager is composed of two subspecies found in Haiti and on Gonâve Island, respectively. Both races are seriously endangered, if not already extinct, and current information on their status is urgently needed. The species should perhaps be considered Critically Endangered. The Eastern Chat-tanager also consists of two subspecies, which comprise three highly fragmented populations in the Dominican Republic. Although having a range that is small in extent, one population apparently is still relatively numerous. Information on the status of the other populations is scanty, but suggests that the two are declining. From recent molecular-genetic studies, it appears likely that the chat-tanagers may not be true thraupids (see Systematics). Regardless of their taxonomic classification, however, all subspecies within this complex are in urgent need of study. Both of these Caribbean countries have suffered a heavy impact from human activity, Haiti ranking among the most environmentally devastated anywhere in the world and having been subjected to the further impact of recent earthquake damage.

Seventeen additional species of tanager are classified as Near-threatened, bringing to 40 the number of tanagers presently listed by IUCN as threatened or close to qualifying as such. This is approximately 14% of all species of Thraupidae as constituted herein. Of these 40, some 23 (57·5%) are Andean in distribution, nine are Brazilian, three are Caribbean, and one occurs in each of southern Mexico, south-western Costa Rica, eastern Panama, north-eastern Venezuela, and northern Peru.

Moreover, it is a sobering thought that, of the family's 283 species, as many as 85, 30% of the total, are restricted-range species. The Chocó EBA alone holds 18 such species.

One of the most important facts that emerges from the above details is that the Andes hold the greatest number of tanager species currently considered to be at risk. This is not surprising, for two reasons. First, the greatest diversity of tanagers is in the Andes, and many of these species have small and ecologically restricted ranges. Secondly, large human populations have been present in the Andes, at least locally, for centuries and have had a larger and often more negative impact on the environment than has been the case in some lowland areas such as the Amazon Basin and even the lowlands of Panama. As a result of this long history of colonization and settlement, anthropomorphic degradation of habitat is extensive in the Andes, and is evident from the lowlands and foothills to the tree-line and even higher. Human-generated habitat degradation in the Atlantic Forest region of east and south-east Brazil, however, is even more severe than that in the Andes, but the total number of affected species is smaller because the region, overall, supports a lower species diversity than the Andes. The destruction of Atlantic Forest on private property in south-eastern Brazil is today almost complete, only a few small, privately held tracts remaining. These and a sprinkling of parks and protected areas scattered the length of this region are all that remains of these once extensive forests.

In virtually every case in which populations of tanagers are declining, the root cause can be traced to anthropogenic disturbances. Deforestation and the conversion of land, including

Human-generated habitat degradation in the Atlantic Forest of eastern and south-eastern Brazil is even more severe than in the Andes. But the number of tanager species affected is smaller, because the region supports a lower species diversity than the Andes. The ***Black-backed Tanager*** *is found in the Atlantic Forest Lowlands Endemic Bird Area, where its total population is estimated at fewer than 10,000 individuals and declining. It is considered Vulnerable, although its distribution is complex and not yet understood. When breeding, it uses coastal sandy-soil forest and scrub, a habitat which is being cleared for beachfront real-estate development.*

[*Tangara peruviana*, Patrimônio Natural de Volta Velha Special Reserve, Itapoá, Santa Catarina, Brazil. Photo: Edson Endrigo]

wetlands, to agricultural use have been and continue to be the most important threats. As human populations expand throughout Latin America, there is continued pressure to convert land for agricultural exploitation. Inevitably, the result is a mosaic of fragmented habitat, which over time places an increasing number of species at risk.

Trapping of birds for the cagebird trade is an additional problem that affects many tanagers, including an unknown number of the species mentioned above, as well as commoner, more widespread ones. The practice continues on an alarming scale, with dozens to hundreds of tanagers, dacnises, honeycreepers and euphonias, as well as cardinalids, fringillids and other small finches, and even fruiteaters (*Pipreola*), offered for sale in thousands of markets all across Latin America on almost any market day. The most highly prized species on offer are, almost invariably, brightly coloured ones, no matter now unsuitable they may be as caged birds. Many of these colourful species are, of course, tanagers, as well as cardinalids, fringillids, emberizids, fruiteaters, parrots and toucans. In addition, a few species are highly sought because they are excellent singers. Tanagers and other small songbirds are, in general, relatively easy to capture by means of a simple and inexpensive technique that involves the placing of a captive, singing bird in a small wooden cage that has several long projecting perches fastened on the outside. The perches are covered with sticky, glue-like tree sap, such as that from a breadfruit tree (*Artocarpus altilis*) or other suitable species; the sap effectively immobilizes any small bird that alights on the perch. In this manner, a single trapper, with a few cages, can capture a remarkable number of birds.

Although many tanagers, as defined by the traditional taxonomy of Thraupidae (see Systematics), are not gifted singers, they are widely sought by trappers for their beautiful colours. A number of species currently classified as emberizids, but genetically closer to tanagers, are excellent singers, among them the seedeaters in the genus *Sporophila* and the seed-finches in *Oryzoborus*. Some of these are highly desired as cagebirds, the Chestnut-bellied Seed-finch (*Oryzoborus angolensis*) being perhaps the most valuable of all because of its beautiful song and its ability to thrive in cages. Indeed, so popular is this species in Suriname and locally in Guyana that an entire subculture of bird-keeping has arisen, one that includes weekend bird singing contests. Champion birds at contests are exchanged for large sums of money and are widely, albeit illegally, exported, as well. The pressure to capture this seed-finch in the wild is so intense that the species is now extremely rare in settled areas across northern Suriname and Guyana, and poachers are expanding their operations illegally into bordering areas where human populations are low and the policing of such large areas is nearly impossible. Many tanagers eat large amounts of fruit in the wild and, perhaps unfortunately, they readily accept it in captivity. Such behaviour makes it relatively easy to keep them in cages. In the same man-

A restricted-range species from the Chocó Endemic Bird Area, the ***Scarlet-breasted Dacnis*** *has an extremely limited distribution in Colombia, where its forest habitat is being lost to a combination of oil palm planting, settlement, logging, ranching and mining, at a rate of 3·8% per year. The bulk of the species' range is in Ecuador, but there its habitat has almost entirely disappeared or become extremely fragmented. Key reserves in both countries are poorly protected. The tanager's population may have fallen by as much as 30% in a decade and it is considered Vulnerable.*

[*Dacnis berlepschi*, Río Silanche Bird Sanctuary, Pichincha, Ecuador. Photo: Dusan Brinkhuisen]

Listed as Vulnerable, the estimated global population of the ***Tamarugo Conebill*** *is around 35,000 individuals. In 1993, its entire breeding range was thought to be just 108 km² of mature tamarugo* (Prosopis tamarugo) *plantations in Chile. Its breeding is timed to coincide with the blooming of tamarugo flowers and the caterpillars which feed on them. Attempts to control these caterpillars with pesticides could affect the entire population. In the meantime, the tamarugo plantations are regenerating and the species may be increasing.*

[*Conirostrum tamarugense*, Chava Valley, Arica, Chile. Photo: Andy & Gill Swash/ WorldWildlifeImages.com]

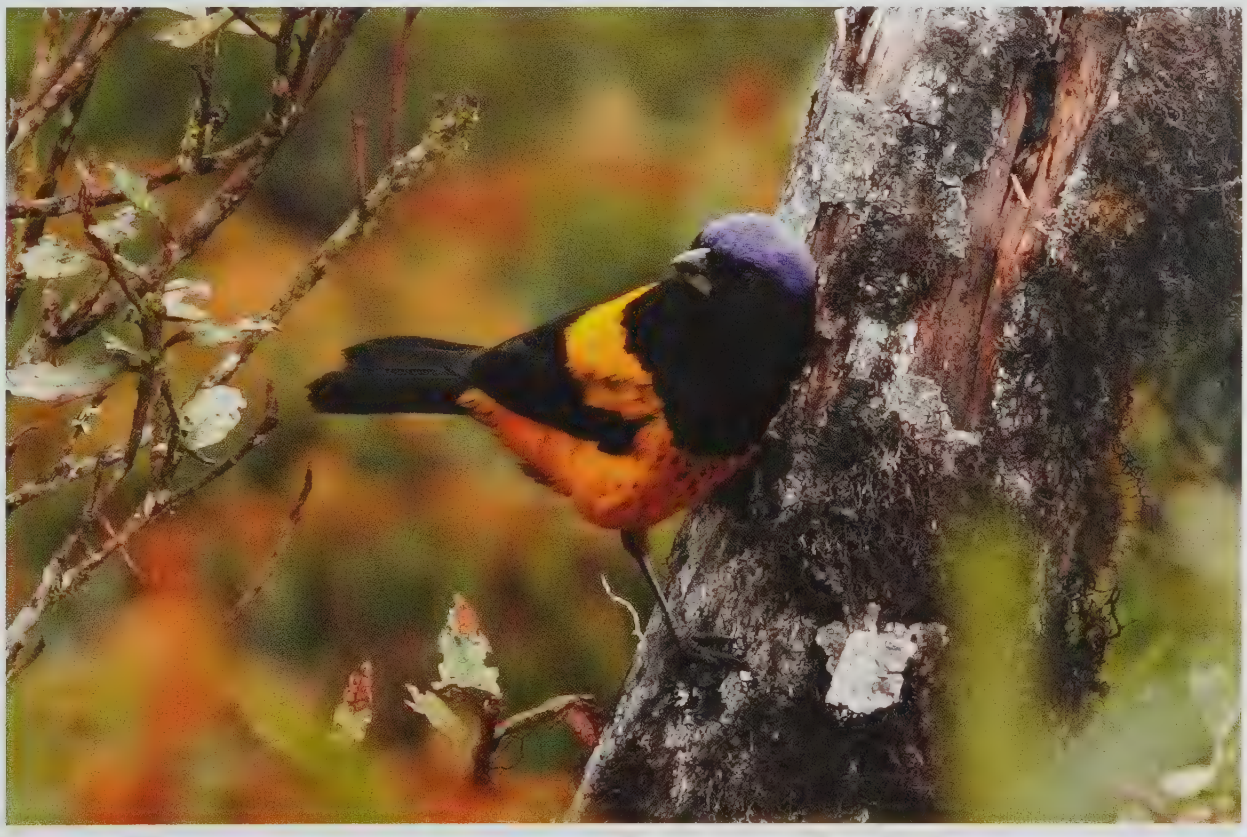
ner, seedeaters and seed-finches can be maintained on a simple diet of seeds. Irrespective of diet and of appropriateness of a species for confinement, however, a great many of the birds captured and offered for sale die prematurely. Mortality among small passerines in captivity is often extraordinarily high, this being due to a combination of inexperience, neglect and ignorance, on the part of both sellers and buyers, of what is required to keep small, wild-caught songbirds healthy in captivity. Often, the birds are poorly treated, confined in cages that are too small, confined in close quarters with incompatible or inappropriate species, fed inappropriate food items, and subjected to rough transport and handling, excessive noise and heat, poor sanitation, and other abuses. All of these factors can increase stress, result in poor plumage condition and cause abnormally high mortality. Many birds die in transport to markets, even before they can be sold. Still more die as they await the selling process in markets.

The transporting of live birds to markets has taken a heavy toll on a few highly prized species. This is especially true of the large consignments that are transported internationally, often in highly inappropriate ways in order to avoid detection by immigration authorities. The welfare of the individuals being transported is typically of secondary consideration. Euphonias seem always to be in great demand, as are colourful species such as the Seven-colored Tanager, which is intensively pursued in eastern Brazil. Colourful mountain-tanagers, and even such common species as the Blue-grey Tanager, are taken with reckless disregard for the damage being done to wild populations. Sadly, some small seed-eating birds and tanager species are now rare or locally extirpated in areas where trappers have access to large markets. As pressure to capture certain species increases, and because international buyers often pay handsomely for coveted species, trappers now range farther afield, and employ ever more sophisticated methods by which to capture and transport the birds, and to avoid detection by authorities. In certain areas, such as Guyana and eastern Venezuela, trappers now illegally cross international borders on a regular basis in search of productive trapping areas.

There are few data on the number of trapped birds being sold in public markets or being funnelled directly into international smuggling conduits, but the numbers are surely large. Similarly, little information, beyond qualitative observations, is available on the effects of intensive, uncontrolled trapping on bird populations, and there are few baseline data on and little monitoring of numbers passing through markets in heavily trapped areas such as the island of Trinidad, eastern Venezuela, the Andes, the Guianas and Brazil, or of birds being smuggled into countries where international shipment is easier. In Trinidad, for example, where euphonias are widely trapped, the Trinidad Euphonia (*Euphonia trinitatis*), once apparently a common and widespread species, is now rare and difficult to find. Comparable examples exist in many areas across Middle and South America.

The ***Eastern Chat-tanager*** *and the Western Chat-tanager* (Calyptophilus tertius) *are regarded as conspecific by IUCN, which classifies them as Vulnerable. The two subspecies of the Western Chat-tanager are certainly seriously endangered, if not extinct. The nominate race of the Eastern Chat-tanager, from the northern coast of the Dominican Republic, has not been seen in recent years and, it, too, may be extinct. The race* neibae *has reportedly declined dramatically, with recent records mainly from Sierra de Neiba and Ebano Verde Scientific Reserve. Given its very small distribution and rapid decline, the species probably deserves to be ranked as Endangered.*

[*Calyptophilus frugivorus neibae*, Sierra de Bahoruco, Dominican Republic. Photo: Doug Wechsler/ VIREO]



*The **Gold-ringed Tanager**, one of six tanager species listed as Endangered, occurs on the Pacific slope of the western Andes of Colombia, in the Chocó Endemic Bird Area. At Cerro Caramanta, on the Antioquia–Risaralda border, it is common to very common in a large forest block, which is intact from 800–1000 m up to 2000 m or more. A proposed highway, however, will run nearby, opening up the area to logging, mining and settlement. Deforestation has been widespread throughout this species' presumed former range, and has been severe on Cerro Tatamá, where the type locality lies within the Tatamá National Park.*

[*Bangsia aureocincta*, El Cairo, Valle del Cauca, Colombia. Photo: Ketil Knudsen]

While human activities such as deforestation and trapping have had a particularly adverse effect on many tanagers, the impact of some anthropogenic changes has been more benign. For example, the partial clearing of middle-elevation mountain forest for shade-grown coffee production in lower Central America and the northern Andes has had far less impact on the environment and on bird populations than has the production of sun coffee, the planting of bananas or oil palms (*Elaeis guineensis*), or cattle-raising, all of which require complete deforestation. Various tanagers in the genera *Hemispingus*, *Eucometis*, *Tachyphonus*, *Ramphocelus*, *Thraupis*, *Pipraeidea*, *Tangara*, *Tersina*, *Cyanerpes*, *Chlorophanes*, *Hemithraupis* and *Conirostrum* utilize or tolerate shade-grown coffee vegetation and make use of the combination of overstorey trees, shrubby edges and, in some cases, the coffee shrubs themselves. Species of *Euphonia* and *Piranga*, now known to be allied genetically with fringillids and cardinals, respectively (see Systematics), also exploit the layered mosaic of vegetation created by shady coffee plantations. While there are few quantitative studies comparing species richness and persistence over time in these habitats, coffee plantations have been widely cultivated for almost two centuries. In the absence of mature forest, shade-grown coffee plantations provide a habitat that, while anthropogenically compromised, is still capable of supporting a surprisingly rich avifauna, albeit one somewhat different from that which may originally have been present. In contrast, sun-grown coffee and other monocultures now widely planted require no overstorey trees and offer few or no opportunities for utilization by birds. Sun-coffee plantations, as well as oil palms, bananas and other monocultures, are ecologically as disastrous to wildlife as is complete deforestation.

A small number of tanagers have profited from human activities and from degradation and alteration of the landscape caused by humans. Several *Thraupis* species, including the Blue-grey, Sayaca, Palm and Blue-capped Tanagers, several species of *Ramphocelus*, including the Scarlet-rumped, Cherrie's, Lemon-rumped and Crimson-backed Tanagers, and one or more *Tachyphonus*, notably the White-lined and Ruby-crowned Tanagers, are today flourishing in numbers almost certainly higher than those historically. In various ways, each of these species is able to use the mosaic of fields, scattered trees, gardens, shrubs and exotic vegetation that now characterize many rural and urban landscapes. Similarly, Black-faced Tanagers, Burnished-buff Tanagers and Scrub Tanagers, all of which thrive in drier open areas and ranchland, have profited from deforestation and have expanded their ranges into areas previously covered by forest.

There are other thraupids that have adapted to, or are able to utilize human-altered environments to varying extents, but it is unclear whether these species, as a whole, have profited or declined significantly. Examples of these include the Magpie Tanager, Hooded Tanager, Flame-rumped Tanager (*Ramphocelus*

*The estimated global population of the **Golden-backed Mountain-tanager** is just 250–2500 mature individuals and is likely to be declining further as a result of loss of habitat, especially tree-line* Polylepis *and other trees and shrubs of elfin woodland. Restricted to the North-east Peruvian Cordilleras Endemic Bird Area, it is known from five areas on the Cordillera Central, in the Peruvian departments of San Martín, La Libertad and Huánuco. It presumably occurs in the unexplored intervening regions, but has not been found in similar habitat farther north. It is possibly to be found most easily in the Carpish Ridge region at Quilluacocha and Bosque Unchog, in Huánuco.*

[*Buthraupis aureodorsalis*, Bosque Unchog, Huánuco, Peru. Photo: Gunnar Engblom]

*The **Azure-rumped Tanager** is confined to the mountains of the Sierra Madre de Chiapas, in Mexico and neighbouring Guatemala. Unfortunately for the species, its altitudinal range coincides with the optimal land for coffee cultivation. Extremely localized and declining, it is listed as Endangered. All recent Mexican reports are from the buffer zone of El Triunfo Biosphere Reserve. In Guatemala, it is known from eight sites, most of which have some legal protection, and within these very restricted areas it appears to be locally common. Revenue from birdwatching tourism is encouraging local communities to conserve these sites.*

[*Tangara cabanisi*, Los Tarrales Reserve, Atitlán Volcano, Guatemala. Photo: Knut Eisermann]

flammigerus), Blue-and-yellow Tanager, Golden-hooded Tanager, Blue-necked Tanager, Plain-colored Tanager, Red-legged Honeycreeper, Rusty Flowerpiercer and Black Flowerpiercer (*Diglossa humeralis*). The expansion and abundance of a few species, which have profited from human activities, however, mask a less sanguine future for the majority of the Thraupidae, which continue quietly to decline in numbers year after year, along with the magnificent forests that have nurtured and sheltered them for millennia. Over time, some of these declining species may disappear completely. Sadly, their loss is often so gradual that their absence, from one human generation to the next, is scarcely noticed, and the fact that they ever existed at all can fade with succeeding generations.

On the positive side, it is remarkable that, given such extensive environmental change across the Neotropics, extinctions are rare, with far fewer recorded than in northern latitudes. The number of species listed as Critically Endangered or Endangered is also comparatively small. Fortunately, environmental awareness is increasing throughout tropical America and, through the efforts of concerned individuals, conservation organizations and national governments, there is hope that these lovely and interesting birds will continue to enrich our lives and find a place for themselves.

*With a global range of about 1000 km², the Endangered **Black-cheeked Ant-tanager** is found only on the Osa Peninsula and around the Golfo Dulce, in south-west Costa Rica. Its range has been halved by deforestation since 1960. As recently as 1989, it was still fairly common in unprotected forest in the Osa Peninsula area. Since then, it has become increasingly scarce and local outside the Corcovado National Park, Golfito Wildlife Refuge and Golfo Dulce Forest Reserve. Populations in these protected areas remain stable and it is still common in Corcovado, but the Golfito Faunal Refuge is increasingly disturbed and fragmented.*

[*Habia atrimaxillaris*, Costa Rica. Photo: Mike Danzenbaker/ AGAMI]

*Listed as Critically Endangered, the **Cone-billed Tanager** was known only from the type specimen, a male, from an uncertain locality in Mato Grosso, in Brazil, in 1938. It went unrecorded until 1993, when what was thought to be a juvenile or female was seen in Noel Kempff Mercado National Park, in Bolivia. From 2003, there were sightings in Das Emas National Park, in Goiás (Brazil) and in 2006 a population estimated at 100 was found 900 km away in Mato Grosso. There could be as much as 1500 km² of suitable habitat in Emas, where the population is unlikely to be fewer than 50. It may prove more widespread and common than was previously thought.*

[*Conothraupis mesoleuca*, Das Emas National Park, Goiás, Brazil. Photo: Edson Endrigo]

*Until a 1998 sighting, the **Cherry-throated Tanager** had not been positively seen in more than 50 years. It was listed as Critically Endangered, but feared extinct. A restricted-range species from the Atlantic Forest Lowlands Endemic Bird Area, it is known from a handful of sites and not reliably found at any of them. Only two groups are definitely known, though a third has recently been confirmed, all at sites in the Espírito Santo montane forest. The Cherry-throated Tanager has been adopted as the symbol of the region, and in 2010 a 37,000 ha "ecological corridor" was designated for the species, with the objective of connecting forest remnants through forest conservation and restoration actions.*

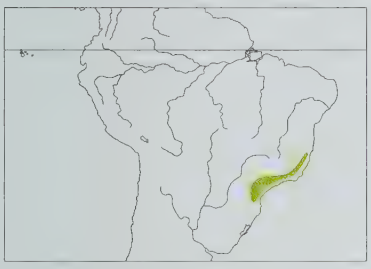
PLATE 1

inches 2
cm 5



Genus *ORCHESTICUS* Cabanis, 1851

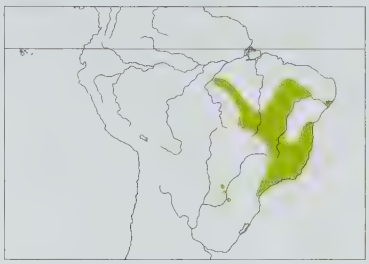
1. Brown Tanager

Orchesticus abeillei

French: Tangara brun **German**: Fuchstangare **Spanish**: Tangara Parda

Taxonomy. *Pyrrhula Abeillei* Lesson, 1839, Rio de Janeiro, Brazil.
Monotypic.
Distribution. SE Brazil from S Bahia S to E Paraná and NE Santa Catarina.

Descriptive notes. 17–18 cm; 31·5 g. Plumage closely resembles that of a *Philydor* foliage-gleaner, but bill thicker, slightly swollen and blackish. Has forecrown, broad eyebrow and face cinnamon, long narrow blackish line from lores extending back through eye to nape; mid-crown and nape brownish, strongly tinged grey, mantle, back and rump medium brown, upperwing-coverts cinnamon-rufous, primary coverts dusky, heavily edged rufous; flight-feathers dusky, edged cinnamon-rufous, more broadly so on inner feathers, tertials mostly cinnamon-rufous with dusky inner webs; tail medium length, squarish, dusky, heavily tinged rufous; throat and underparts, including undertail-coverts, dull cinnamon-buff, underwing-coverts orange-buff; iris dark red; bill blackish; legs horn. Sexes similar. Immature is much like adult, but duller. Voice. Dawn song an extremely high-pitched "sis-sis-sis-sis'sis'sssssssssssssst", the last extended phrase a buzzy, rising hiss, weak and easily overlooked (thin rising phrases, at a distance, resemble some vocalizations of *Thraupis*); day song may be similar to dawn song or varied somewhat, e.g. a few buzzy or lisping notes preceded or followed by very high-pitched, thin jumble of notes. Calls during foraging extremely high-pitched and weak "tsee" or "tee" notes.
Habitat. Mainly humid pre-montane and montane forest; also upper levels of thinned or open woodland, second growth and tall trees around settled areas. At 750–1600 m.
Food and Feeding. Insects; reported also as taking fruit. Forages in pairs and small groups high in canopy. Hops or clambers along shady branches and in foliage; peers at leaf surfaces, probes dead-leaf clusters, bromeliads, moss, lichens, even spider webs, then lunges or sallies for insects. Habitually forages with mixed-species flocks and tends to perch in rather upright posture; in SE Brazil, frequently found in same mixed flocks as very similar-looking Buff-fronted Foliage-gleaner (*Philydor rufum*).
Breeding. Season at least Oct in Rio de Janeiro. In possible instance of courtship display, male and female faced each other, motionless and upright, with wings drooping, tail depressed and spread. One nest found, in bromeliad on side of tree trunk; 2 eggs, presumably from same clutch, were pinkish-white, blotched pale chestnut and dark reddish-brown, with a few lavender specks, mostly at larger end. No other information.
Movements. Not well documented. Birds from at least Espírito Santo and Rio de Janeiro reported as migrating N to S Bahia during coolest months of year.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to fairly common. Inhabits montane forests in Atlantic coast region, and these have suffered less from deforestation than have nearby lowland areas; in N part of range, in Bahia (especially in wintering area), deforestation has been extensive and, moreover, most remaining patches of forest have been damaged or cut and burnt for conversion to agricultural crops and cattle ranching. Occurs in several protected areas, among them Itatiaia and Serra dos Órgãos National Parks, but is now vulnerable because remaining protected areas are isolated, and almost all unprotected areas are at risk of deforestation.
Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Davis (1945b, 1946), Diamond & Lovejoy (1985), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Ogilvie-Grant (1912), Parker & Goerck (1997), Pelzeln (1869), Pimental (2006), Planqué (2005), Ridgely & Tudor (1989, 2009), Sick (1985, 1993), Stattersfield & Capper (2000), Willis (1976b, 1989).



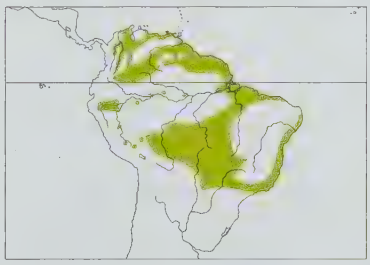
Genus *SCHISTOCHLAMYS* Reichenbach, 1850

2. Cinnamon Tanager

Schistochlamys ruficapillus

French: Tangara cannelle **German**: Gimpeltangare **Spanish**: Tangara Canela

Taxonomy. *Saltator ruficapillus* Vieillot, 1817, Rio de Janeiro, Brazil.
Recent molecular data indicate that present genus, *Cissopis* and *Neothraupis* are one another's closest relatives. Three subspecies recognized.
Subspecies and Distribution.
S. r. capistrata (Wied, 1821) – E Brazil from S Pará, S Maranhão, C Piauí, N Goiás and S Bahia (also E Pernambuco and Alagoas) S to C Minas Gerais.
S. r. sicki Pinto & Camargo, 1952 – E Mato Grosso, in S Brazil.
S. r. ruficapillus (Vieillot, 1817) – E Paraguay, NE Argentina (N Misiones) and SE Brazil (S Minas Gerais S to E Paraná).
Descriptive notes. 16–18 cm; 24–39 g. Nominate race has forehead, lores, ocular area and chin black, forming small but prominent mask, this surrounded by cinnamon-buff which extends to side of head, neck and middle breast; central crown and nape dusky grey, nape and upperparts pearly



bluish-grey to medium grey; tail dusky grey, medium length; upperwing-coverts mostly grey (inner feather webs dusky, outer webs mostly grey), primary coverts blackish; flight-feathers dusky, edged grey, inner flight-feathers (especially tertials) more broadly edged grey, outer web of tertials entirely grey; flanks light grey to greyish-white, centre of lower breast and belly white, undertail-coverts contrasting rich cinnamon-buff; iris reddish-brown; bill thick, blue-grey, distal half of upper mandible and tip of lower mandible black; legs dusky. Sexes similar. Immature and subadult are similar but duller, with foreface dusky, throat and breast dull buffy yellow (paler than adult). Races differ minimally: *capistrata* is smaller and shorter-tailed than nominate, also duller on head, much paler cinnamon on throat and breast; *sicki* is generally richer and slightly darker in colour tone. Voice. Song a leisurely and exceptionally sweet, musical series of phrases, typically at least some phrases repeated once or twice, e.g. "wee-chur-chur, pur-tee, pur-tee, we-chur, we-tur-tur...", duration c. 4 seconds; some geographical variation in song phrases, but pattern and rich melodic tone easily recognizable; reminiscent of song of a number of *Sporophila* seedeaters. Call rather low-pitched, reedy or slightly hoarse, "jreeet", occasionally doubled; resembles calls of various *Ramphocelus* tanagers.
Habitat. Scrub and bushes in *cerrado* and *caatinga*, low open woods and park-like areas, forest edges, riparian woodland, and brushy partly open terrain. Often in damp or wet areas within dry regions, and reported as numerous in high-elevation grassy meadows and openings in wooded areas. Occurs in open low woody scrub vegetation mixed with grass (*campo sucio*) at W end of range in Chapada region of Mato Grosso. Common in high, cold, montane meadows in Serra do Caparaó and Minas Gerais, and in some areas occurs together with *S. melanopis*. Sea-level to c. 1200 m; locally to 2050 m.
Food and Feeding. Feeds heavily on fruit, including *Morus*, herbaceous pokeweed (*Phytolacca*), also some insects. Of four stomachs examined, one contained only vegetable matter, one only animal matter, and two contained both, including seeds, fruit, Hymenoptera (bees and ants) and beetles (Coleoptera). Forages alone and in pairs in bushes and thickets; may move higher along forest borders.
Breeding. One record of breeding in Dec in S Brazil (Minas Gerais). Clutch 2 eggs, yellowish-white, densely spotted with dark brown. No other information.
Movements. Few data. Possibly migrates seasonally away from parts of C Brazil. In winter months when not breeding, may move locally, gathering around palms planted in settled areas.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Race *sicki* known only from type locality, Xavantina, in E Mato Grosso. Extensive human disturbance and settlement occurs within this species' range as native habitat converted into pastureland and cropland. This species tolerates or is able to utilize a variety of intervened habitats, and is therefore buffered somewhat from near-term risks. Occurs in a number of protected areas, among them Augusto Ruschi Biological Reserve and Itatiaia National Park, both in Brazil. Several recent sight records in and close to Iguazú National Park, in NE Argentina.
Bibliography. Albano (2004), Burmeister (1856), Burns (1997a), Diamond & Lovejoy (1985), Dunning (1982), Erickson & Mumford (1976), Forbes (1881), Fry (1970), Goeldi (1894), Gagliardi (2007a), Ihering (1902), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Mitchell (1957), Moojen *et al.* (1941), Parker & Goerck (1997), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Schubart *et al.* (1965), Sick (1985, 1993), de Vasconcelos *et al.* (2005), Zapata (2002).

3. Black-faced Tanager

Schistochlamys melanopis

French: Tangara à camail **German**: Schleiertangare **Spanish**: Tangara Carinegra

Taxonomy. *T.[anagra] melanopis* Latham, 1790, Guiana.
Recent molecular data indicate that present genus, *Cissopis* and *Neothraupis* are one another's closest relatives. Five subspecies recognized.
Subspecies and Distribution.
S. m. aterrima Todd, 1912 – Colombia in middle (probably also lower) Cauca Valley, middle and upper Magdalena Valley, locally Sierra Nevada de Santa Marta area, Perija Mts, and E of Andes in *llanos* (Casanare S to Caquetá and Putumayo and E to Vichada, Guainia and Vaupés), E locally through parts of N & S Venezuela to W Guyana and N Brazil (Cerro Uei-tepui).
S. m. melanopis (Latham, 1790) – E Guyana, Suriname, French Guiana and NE Brazil.
S. m. grisea Cory, 1916 – extreme S Ecuador, and E Peru on E slope of Andes (very locally from Moyobamba and Huarandosa S to Marcapata).
S. m. olivina (P. L. Sclater, 1865) – extreme SE Peru (Pampas del Heath) and adjacent N Bolivia E to SC Brazil (Mato Grosso).
S. m. amazonica J. T. Zimmer, 1947 – Brazil S of R Amazon E to N Ceará, then S to Mato Grosso, São Paulo and Rio de Janeiro, and up E coast to Pernambuco.

Descriptive notes. 17–18 cm; 29–40 g. Slender open-country tanager with grey body and black foreparts. Nominate race has forehead to mid-crown, side of head, throat and chest brownish-black, rear crown and upperparts to uppertail-coverts dull medium grey; central tail feathers dark grey, rest of tail feathers dusky, edged grey; bend of wing white mixed with grey; upperwing-coverts dusky, broadly edged and tipped grey, primary coverts medium grey; flight-feathers brownish-dusky, narrowly edged grey, tertials mainly brownish-grey, outer half of tertial feathers dull grey; underparts below chest pale grey (paler than

On following pages: 4. Magpie Tanager (*Cissopis leverianus*); 5. White-banded Tanager (*Neothraupis fasciata*); 6. Black-and-white Tanager (*Conothraupis speculigera*); 7. Cone-billed Tanager (*Conothraupis mesoleuca*); 8. Red-billed Pied Tanager (*Lamprospiza melanoleuca*); 9. Scarlet-throated Tanager (*Compsothraupis loricata*); 10. White-capped Tanager (*Sericossypha albocristata*); 11. Hooded Tanager (*Nemosia pileata*); 12. Cherry-throated Tanager (*Nemosia rourei*); 13. Rufous-crested Tanager (*Creurgops verticalis*); 14. Slaty Tanager (*Creurgops dentatus*).

upperparts), becoming whitish on centre of belly; underwing-coverts white mixed with grey; iris reddish brown; bill thick, blue-grey with broad blackish tip; legs blackish. Sexes similar. Immature is distinctive, entirely olive with slight yellowish tinge above, paler olive-yellowish below, with narrow eyering (sometimes broken at front and rear) yellowish, tail dusky with olive tinge, wing-coverts and flight-feathers dusky brown with dull olive yellow edgings; older immature has variable amounts of black mottling on face and bib while still in olive plumage. Race *aterrima* is slightly larger than nominate, distinctly black (not brownish-tinged) on head and throat, and back duller grey; *amazonica* is overall darkest race, with more bluish-tinged back, and with face and throat colour intermediate between previous and nominate; *grisea* is like nominate but larger and darker, with slightly bluer tinge on back; *olivina* is intermediate in size and colour between previous and nominate. Voice. Song a musical, rambling series of whistled notes, "Swéet, right here for me", or similar phrase, rising, falling, and often repeated 3–4 times in succession; also a rather weak "tee-tseet-tseet-tseet" and other rambling, disconnected phrases; in Peru described as resembling song of a *Pheucticus* grosbeak or saltator (*Saltator*) but shorter and simpler in structure, "weeo wurchick weeo wurchick, twee-twee-twee". Calls include sharp "swik" and "spit-churt".

Habitat. Dry to moist grassland with scattered shrubs, bushes and scrubby trees, and grassland or grassy slopes with patches of scrubby woody vegetation; less often in low open or thinned woodland. In Brazil in *cerrado*, *restinga*, brushy open country and marshes with patches of shrubs. In all areas readily invades deforested areas opened for pasture and cultivation; now occupies many deforested areas in Andean foothills. Widespread at low elevations, also locally in Andes to at least 1800 m in Venezuela, 1700 m in Colombia; in S Ecuador reported at 650–1700 m (once to 1800 m); in Peru mainly 900–1800 m, but also very locally in E lowlands.

Food and Feeding. Variety of fruits, seeds and arthropods. Stomach contents fruit, berries, seeds, also ants (Formicidae) and other insect remains; of six stomachs examined, two contained only vegetable matter and two only animal matter, and two contained both. A pair in NW Bolívar (Venezuela) regularly ate small, very hot peppers in a garden. Forages singly and in pairs; also, family groups of three or more regularly seen. Perches in shrubs and bushes, often within vegetation, where inconspicuous. Peers around, but not an active forager; most searching consists of some lethargic hopping within confines of a shrub, and then often apt to fly off some distance to another shrub or patch of scrubby vegetation.

Breeding. Recorded in Jan in Suriname and Sept in Brazil (Mato Grosso); in Colombia, birds in breeding condition in Mar–Jun in Andes and Jan and Apr E of Andes. Open cup-nest of grass placed in shrub or grass in grassland; one in Suriname was 0·4 m above ground in grass. Clutch 2 eggs, greyish-white to yellowish-white, thickly streaked and blotched dark brown; no information on incubation and nestling periods. In Brazil, nests reported as frequently parasitized by Shiny Cowbird (*Molothrus bonariensis*).

Movements. Apparently migrates seasonally from parts of C Brazil; elsewhere no movement reported.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common, and widespread. Has profited from deforestation, especially in Andes. First reported in extreme S Ecuador in 1986, and now extending range there; is expected also to spread S from Colombia into NE Ecuador. Occurs in many protected areas over wide range. Within this range extensive suitable habitat exists and, as deforestation continues, even more is becoming available. No serious short-term risks identified.

Bibliography. Genus *CISSOPIS* Vieillot, 1816

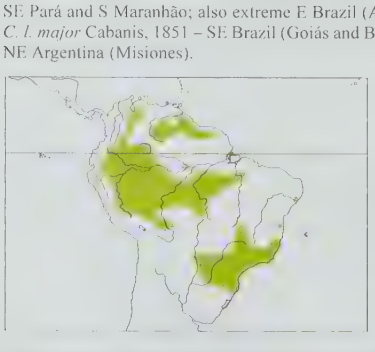
4. Magpie Tanager

Cissopis leverianus

French: Tangara pillurion **German**: Elstertangare **Spanish**: Tangara Urraca



Taxonomy. *Lanius leverianus* J. F. Gmelin, 1788, no locality = French Guiana.

Recent molecular data indicate that present genus, *Schistochlamys* and *Neothraupis* are one another's closest relatives. Two subspecies recognized.

Subspecies and Distribution.

C. l. leverianus (J. F. Gmelin, 1788) – W & E Venezuela (on both slopes of Andes, and S of R Orinoco) E to French Guiana and Brazil (N Roraima), also Colombia (E slope of Andes S from Norte de Santander) S to Bolivia (Santa Cruz) and E across Brazil S of Amazon to C Mato Grosso, SE Pará and S Maranhão; also extreme E Brazil (Alagoas, possibly also Pernambuco).

C. l. major Cabanis, 1851 – SE Brazil (Goiás and Bahia S to N Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

Descriptive notes. 25–26 cm, 73–86 g (*leverianus*); 29 cm, one male 75·8 g and two females 67·5–71 g (*major*). Large, long-tailed species with bold black-and-white plumage. Nominate race has entire head to upper back, neck, throat and chest to point on mid-breast glossy blue-black, forming shaggy hood; middle back, scapulars, rump and uppertail-coverts white; tail long and strongly graduated, black, feathers with large white tips (visible mainly from below when bird perched); upperwing-coverts black, greater coverts with variable amounts of white but often with just a few white-tipped feathers (less often a few median coverts also with small white tips), lesser coverts usually concealed by long white scapular feathers; flight-feathers black, tertials with broad white edges and rounded tips; underparts below central breast white; iris yellow; bill short and thick, black; legs strong, blackish, tarsus short. Sexes similar. Immature resembles adult. Race *major* differs from nominate in larger size, longer tail, more extensive black on back (only rump white), and tertials more narrowly edged and tipped white or only outer half tipped white. Voice. Not especially vocal. Most often heard are loud, metallic "chink" notes, given as pair flies across clearing; occasionally a thin squealing "sweeeee" and "eechúk". Variable and infrequently heard song a short series of low, raspy notes and rattles followed by a few squeaky notes, e.g. "t-t-t-t-t-ttreeek-treek-treeek, titl-titl-tleechuk-chuk", jerky or irregular. Race *major* often gives rapid 3-syllable phrases; a common phrase in one recording was "swikit swee swee".

Habitat. Shrubby clearings in floodplain-forest or *terra firme* forest, disturbed areas and openings along river edges, on river islands, in plantations and gardens, and in bushy areas along forest borders; also in canopy of rather open second-growth woodland. Lowlands and foothills to c. 1200 m, less frequently to 2000 m in Andes of Venezuela; rarely, to 2000 m in Peru (Urubamba Valley).

Food and Feeding. Arthropods and fruit. Has been noted as taking berries of *Hamelia patens* and *Phytolacca*, and small, hard green buds, and regularly feeds on *Cecropia* catkins. Of 26 stomachs examined, nine contained only vegetable matter and two only animal matter; 15 contained both, including fruit pulp, seeds, spiders (Araneae), caterpillars, and hymenopterans. Usually in pairs or in families of three or four in breeding season; less frequently in groups of five or more when not breeding. May briefly associate with other birds in small fruiting trees, but as a rule not with mixed-species flocks; reported as sometimes associating with Black-throated Grosbeak (*Saltator fuliginosus*) in E Brazil (Espírito Santo). Forages from eye level or lower to well up in tall second growth, and regularly perches on tops of shrubs and or even fairly tall trees. Foraging movements appear to be limited mainly to hopping and peering, sometimes almost in manner of a jay (Corvidae), in fairly open shrubbery and shady second growth.

Breeding. Breeding recorded in Oct in SE Brazil (Rio de Janeiro). Cup-nest of twigs, plant material and grass, occasionally leaves, placed in branch fork and concealed by foliage in shrub or small tree, once 3·5 m above ground; one nest reported 1·4 m up in tree cavity. Clutch 2 eggs, ashy brown to reddish-brown, densely spotted brown; incubation period 12–13 days; nestling period 15 days.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common and widespread. Deforestation has greatly reduced populations in SE & E Brazil. On the other hand, benefits from creation of small clearings and subsequent regrowth of bushy vegetation; has profited from regrowth following extensive forest clearing in Andean foothills. Found in many protected areas across broad range, including Canaima National Park (Venezuela), Iwokrama Forest Reserve (Guyana), Brownsberg Nature Park (Suriname), Amacayacú National Park (Colombia), Yasuní National Park and Cuyabeno Reserve (Ecuador), Manu National Park (Peru), and Serra do Divisor, Pacaás Novos, Iguaçu and Itatiaia National Parks (Brazil).

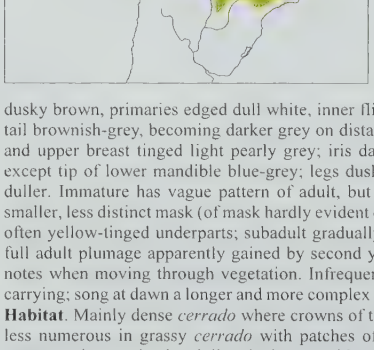
Genus *NEOTHRAUPIS* Hellmayr, 1936

5. White-banded Tanager



Neothraupis fasciata

French: Tangara unifascié **German**: Flügelbindentangare **Spanish**: Tangara Bandeada
Other common names: Shrike-like Tanager

Taxonomy. *T.*[*anagra*] *fasciata* M. H. C. Lichtenstein, 1823, São Paulo, Brazil.

Recent molecular data indicate that present genus, *Schistochlamys* and *Cissopis* are one another's closest relatives. Monotypic.

Distribution. E & S Brazil (from C Maranhão and C Piauí S to Mato Grosso do Sul, São Paulo and Minas Gerais; also SE Amapá), NE Bolivia and NE Paraguay. Recent record from S Suriname.

Descriptive notes. 16 cm; 26–32 g. Plumage pattern strikingly similar to that of several *Lanius* shrikes of N latitudes. Male has crown, nape and upperparts to uppertail-coverts medium grey, broad black mask extending from forehead through lores and eye to rear cheek and surmounted by narrow white line (usually visible) over and behind eye; bend of wing and lesser and median upperwing-coverts black, median coverts broadly tipped white (forming prominent white wingbar); outer half of greater coverts (bottom half when wing folded) black, inner half dusky with broad grey edges; primary coverts black; flight-feathers dusky brown, primaries edged dull white, inner flight-feathers edged grey, tertials brownish-grey; tail brownish-grey, becoming darker grey on distal third; throat and lower underparts white, chest and upper breast tinged light pearly grey; iris dark reddish-brown; bill thick, mostly dusky, all except tip of lower mandible blue-grey; legs dusky horn. Female is similar to male, but slightly duller. Immature has vague pattern of adult, but is much duller and brownish (less grey), with smaller, less distinct mask (of mask hardly evident on younger birds), smaller white wing patch, and often yellow-tinged underparts; subadult gradually acquires crisp blacks and greys of adult, with full adult plumage apparently gained by second year. Voice. Gives frequent weak high chipping notes when moving through vegetation. Infrequently heard day song short, twittery and not far-carrying; song at dawn a longer and more complex whistled phrase that may be performed as a duet.

Habitat. Mainly dense *cerrado* where crowns of trees shade more than 50% of ground; somewhat less numerous in grassy *cerrado* with patches of semi-deciduous trees 7–15 m high, and least numerous in grassland and disturbed areas with scattered trees. In E Bolivia found in open woodland with thick grass and low bushes. Mostly at c. 500–1100 m, mainly on flat tablelands.

Food and Feeding. Mostly insects and other arthropods; also variety of small fruits, including those of *Annona*, *Miconia*, *Eugenia*, *Palicourea*, *Cascaria* and *Byrsonima*; in Brazil, family groups

observed foraging extensively for nectar in *Pseudobombax*-like blossoms of shrub in Jun in Chapada of Mato Grosso. Of seven stomachs examined, six contained arthropods, including ants (Formicidae), beetles (Coleoptera), spiders (Araneae), and a small land snail (Pulmonata); remaining stomach contained seeds. When not breeding found in groups of 5–12 (average 7), which are often with mixed-species flocks or form core elements of these flocks. Forages extensively by dropping to ground or into grasses and herbaceous vegetation, apparently often to pursue dislodged prey, and regularly spends considerable time foraging by hopping on ground, where it keeps near cover. Also regularly follows fires through *cerrado* to capture insects from ground. When group descends to ground to feed, typically a sentinel remains perched higher. Also forages fairly quickly and steadily through savanna trees and bushes such as *Curatella* and *Byrsonima*, where it peers and picks insects from leaves, branches and trunks, behaviour suggesting that of *Tachyphonus* tanagers.
Breeding. Breeding recorded in Oct–Nov in C Brazil (Goiás). One or more offspring from a previous generation may help with nesting activities. Large, deep cup-nest of twigs and straw, lined with fine grass, usually well hidden among leaves and branches of small tree. Clutch 2–3 eggs (more often 3). No other information.
Movements. Uncertain; reported as possibly migratory in SC Mato Grosso, but no recent mention of seasonal movements.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Uncommon to fairly common locally. Despite forming small flocks, is seldom very numerous. In Paraguay, recent records from San Pedro and Canindeyú, and historically S to Caaguazú. Much of the *cerrado* habitat across E & S Brazil has been destroyed and converted into farmland for soybeans and cattle pastures. This species' present population (now fragmented) represents only a fraction of the original, and should be monitored. May occur in some or all of the following protected areas: Brasilia, Das Emas, Pantanal Mato-grossense and Ilha Grande National Parks, in Brazil.

Genus *CONOTHRAUPIS* P. L. Sclater, 1880

6. Black-and-white Tanager

Conothraupis speculigera

French: Tangara à miroir blanc **German**: Spiegeltangare **Spanish**: Tangara Albinegra

Taxonomy. *Schistochlamys speculigera* Gould, 1855, Rio Ucayali, Peru.
Placement of genus in present family has been questioned. Has been suggested that this species could be close to genus *Sporophila*, currently in Emberizidae, or that bill shape is more like that of a fringillid finch. On the other hand, has been suggested that it is conspecific with *C. mesoleuca*, but recent evidence points to the contrary. Monotypic.
Distribution. Breeds W slope of Andes from W Ecuador (Pichincha, Azuay, El Oro and Loja) S to NW Peru (Lambayeque and La Libertad); migrates to E slope and base of Andes (very locally Amazonas, Cajamarca and San Martín) and E lowlands of Ucayali and Madre de Dios, in Peru.

Descriptive notes. 16–16·5 cm; 23–28 g. Male has entire head to throat, upper breast and back black, lower back, rump and uppertail-coverts grey, contrasting black longest uppertail-coverts and tail; upperwing-coverts and flight-feathers glossy black, white band near base of flight-feathers (formed by outer webs of feathers); black of breast sharply demarcated from white centre of lower breast and belly; sides and flanks light grey; underwing-coverts white; iris red-brown; bill fairly thick, mostly pale bluish-grey, tip black; legs dark grey. Female has head and upperparts olive, primary coverts blackish, tail dusky with olive edges; white below, palest on throat and lower underparts, throat very lightly tinged olive-yellow, breast more heavily washed olive and with indistinct blurry olive streaking, lower breast and belly buff-white or tinged yellowish white; weakly indicated broken whitish eyering. Juvenile is like female; immature male like female, but breast more heavily washed yellowish-olive, older male with some black on face and malar area but retains pale eyering. Voice. Song of male a loud, clear "kréé-uung, kréé-uung", repeated several times, with loud, abrupt quality of Scrub Blackbird (*Dives warczewiczi*).
Habitat. Dry deciduous woodland, arid semi-open scrub with grass and borders of humid forest, and second growth or disturbed woodland. Appears to occupy variety of different habitats at different times, not necessarily on regular or seasonal basis; apparently well adapted to dispersing over dry and arid regions in search of localized rainfall for foraging and breeding. Widely scattered non-breeding records from E of Andes in Peru are from forest edges, river borders, second growth and various openings in regions of humid lowland forest. In Ecuador recorded mainly 500–1700 m when breeding (occasionally or locally to 1950 m); in Peru, up to c. 1500 m in dry NW and mostly below 600 m E of Andes.
Food and Feeding. Of 30 stomachs examined, 23 contained only animal matter and seven contained a mixture of plant and animal matter; items included smooth and hairy caterpillars, small spiders (Araneae), a medium-sized orthopteran, moths (Lepidoptera), beetles (Coleoptera), bugs (Hemiptera), a small bee or wasp (Hymenoptera), leaflets, and seeds. Most often seen singly or in pairs or small groups; occasionally reported in flocks of more than 50 individuals. In NW Peru, large flocks foraged mainly in weedy understorey in patches of tall mesquite (*Prosopis*) woodland, where presumed to be searching for insects (but could not be observed or approached in dense vegetation). Forages also in crown or canopy of small trees (3–12 m), where it hops along thin branches and perches upright or reaches out to pick insects from mesquite leaflets. Individuals also may perch quietly for extended periods of time well above ground.
Breeding. Breeds mainly during Feb–May rainy period. Nest in Ecuador a loosely woven untidy cup made from small sticks, twigs and leaf petioles, lined with brown and/or black fungal rhizomorphs, placed up to 1·75 m above ground in shrubbery, hedgerow or small sapling, usually well concealed, sometimes low down (0·5 m) in shrubby weeds; in NW Peru, laying female flushed from thicket of tall grass and weeds on steep slope above ditch may have had nest on or close to ground. Clutch 3–4 eggs, whitish to pale blue with variable amount of reddish-brown and blackish blotches and speckles, markings sometimes concentrated at blunt end; no information on incubation and nestling periods. Parasitism by Shiny Cowbird (*Molothrus bonariensis*) recorded.
Movements. Not well understood; in many areas perhaps only a seasonal or periodic visitor, erratic and unpredictable in occurrence. In general, found in dry to arid regions in W Ecuador and NW Peru during first half of year and then migrates E across Andes into SW Amazonia, but much variation in this pattern. In SW Ecuador and NW Peru seems to be nomadic, appearing and breeding after heavy rains or when rainfall sufficient to produce suitable vegetation; during such times can appear in large single-species flocks. Post-breeders believed to disperse across low Andean passes to E slope or to Amazonia for varying periods of time, but appear not to be resident there; recorded Jun–Sept in Amazonian Peru, but probably present for longer. Evidence to date suggests that the species' presence on E slope or in E lowlands represents periodic dispersal.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Rare to uncommon throughout much of range; locally common in SW Ecuador (especially SW Loja). Status difficult to assess owing to the species' erratic and/or periodic movements; is also generally inconspicuous and hard to see, even when singing. Breeding reported for W slope of Andes in Ecuador and NW Peru, but not for E slope or E lowlands of either country. Heavily dependent on local rainfall; if even marginal scrub and woodland remain intact, threats due to habitat degradation seem unlikely. Fieldwork required in order to clarify its ecological requirements and biology.
Bibliography. Anon. (2010a), Best *et al.* (1993), Burns (1997a), Burns *et al.* (2002, 2003), Butchart & Stattersfield (2004), Carriker (1933, 1934), Coopmans *et al.* (2004), Greeney *et al.* (2006), Ingels (2007), Isler & Isler (1999), Lebbin (2005, 2006a), Meyer de Schauensee (1966, 1970a), O'Neill (1966), O'Neill & Pearson (1974), Remsen *et al.* (2010), Ridgely (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Stattersfield & Capper (2000), Storer (1960), Taczanowski (1884), Witt (2005), Zimmer (1947b).

7. Cone-billed Tanager

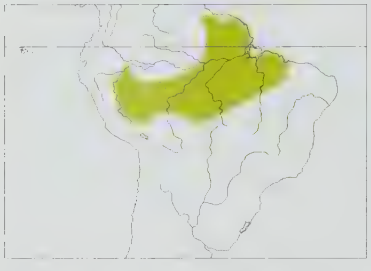
Conothraupis mesoleuca

French: Tangara de Berlioz **German**: Witwentangare **Spanish**: Tangara Picuda

Taxonomy. *Rhynchothraupis mesoleuca* Berlioz, 1939, Juruena, c. 490 km NW of Cuiabá, Mato Grosso, Brazil.
Placement in present family has been questioned. Sometimes placed in a monotypic genus, *Rhynchothraupis*. On the other hand, has been suggested as being conspecific with *C. speculigera*, but new vocal information and knowledge of female plumage (female formerly unknown) indicate that it could be most closely related to White-naped Seedeater (*Dolospingus fringilloides*), currently placed in family Emberizidae. Further research required. Monotypic.
Distribution. W Mato Grosso (upper R Juruena basin) and SW Goiás (Das Emas National Park), in SC Brazil.

Descriptive notes. c. 12–14 cm; one male 15 g, one female 15·5 g. Male is mainly black with greenish gloss; centre of breast and belly white; small white patch at base of primaries, white underwing; iris dark brown; bill thick, pale blue-grey to whitish; legs greyish-brown to black. Differs from *C. speculigera* mainly in smaller size and lack of grey on rump and flanks. Female is plain grey-brown, slightly paler below, with breast pale olive-brown and centre of lower breast and belly buffy white; bill pale dull olive, legs dark brown. Juvenile not described; immature male has darker bill than adult, dark blue-grey, changing to adult colour from base to tip. Voice. Three-part song of male consists of several musical notes, followed by 2 slightly lower-pitched notes extended into trills, and finally a very high-pitched trill, e.g. "tche, tche, tche, tche, tche, tcherrrrrrrrrrrr, tcherrrrrrrrr, tiiiiiiiiiiiiiiiiiiiiii". Also has loud song on descending scale and ending with short metallic "tzi" (Mato Grosso), or faster and ending with even shorter ascending note (Goiás). Both sexes give loud "chank" call, similar to that of *Ramphocelus carbo* but somewhat more metallic.
Habitat. In Mato Grosso inhabits flooded areas along rivers, e.g. seasonally flooded forest and flooded grassland with scattered shrubs and moriche palms (*Mauritia flexuosa*), below c. 120 m; in Goiás, found also in brushy semi-deciduous to evergreen gallery forest, usually near water, and below 300 m. Type specimen said to have been found in bushy vegetation in dry forest in transition zone between Amazonian rainforest and open *cerrado* at c. 200 m (much of this habitat in the region now cleared).
Food and Feeding. Insects; also seeds. In upper R Juruena region (Mato Grosso), seen to catch small aerial insects during rapid sallies, returning to same perch each time; also, frequently observed to eat seeds, including those of bamboo and grasses (including exotics such as *Brachiaria*). Forages singly and in pairs. Generally below 5 m in shrubs; occasionally perches at tops of trees.
Breeding. No information. Apparently territorial.
Movements. No information. Population in Goiás appears largely confined within the boundaries of Das Emas National Park, as almost all surrounding terrain now converted to agricultural use.
Status and Conservation. CRITICALLY ENDANGERED. Uncommon to rare, and very local. Until 2003 known only from a single male specimen, taken in 1938 in WC Brazil, apparently from or near Juruena telegraph post, in Mato Grosso; in 1993, a female/juvenile tanager in Noel Kempff Mercado National Park, in Bolivia, was thought to be of this species, but identity remains unconfirmed (female of present species was at that time undescribed). In 2003, the species was found in Das Emas National Park, in Goiás, where song was tape-recorded, and between then and 2007 there were six sightings, including the first of the female, from four different locations within the park; a few recent sightings of up to three individuals have been made; estimated that the park could contain as many as 250 individuals, although true number likely to be far lower. In 2006, another small population was located 900 km to the NW, along the upper R Juruena and surrounding area, in Mato Grosso; subsequently, a minimum of 40 individuals was recorded at a total of 18 sites there, and the population in this region is thought to number perhaps fewer than 100 individuals. With more information on this species' voice and habitat requirements now available, it could prove to be somewhat more widespread; intensive fieldwork in the appropriate habitats is urgently needed. Protection appears secure at Das Emas National Park, where it has been estimated, perhaps generously, that up to 1500 km² of suitable habitat exist. In W Mato Grosso, the Chapada dos Parecis region (which extends widely across and beyond the upper Juruena basin) contains several areas of potentially suitable habitat not yet visited by ornithologists, and these areas, a mosaic of private and indigenous lands, certainly merit special surveys. A major threat is presented by planned hydro-electric developments on the upper Juruena, which could threaten this species' survival there.

Bibliography. Anon. (2010a), Berlioz (1939), Bond (1951b), Butchart & Stattersfield (2004), Buzzetti & Carlos (2005), Candia-Gallardo *et al.* (2010), Hellmayr (1936), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Sick (1985, 1993), Souza (2002), Stattersfield & Capper (2000), Storer (1960), Tobias *et al.* (2006), Zimmer (1947b).



Genus *LAMPROSPIZA* Cabanis, 1847

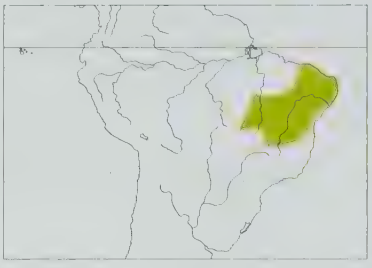
8. Red-billed Pied Tanager

Lamprospiza melanoleuca

French: Tangara noir et blanc **German**: Rotschnabeltangare **Spanish**: Tangara Piquirroja
Other common names: Red-billed/Pied Tanager

Taxonomy. *Saltator melanoleucus* Vieillot, 1817, French Guiana.
Recent genetic data indicate that this genus is probably not closely related to other thraupids, but no closely related family or sister-taxon has yet been identified; retained in present family pending further information. Monotypic.
Distribution. Lowlands of SE Peru (S Loreto S to Madre de Dios and N Puno) and N Bolivia (Beni) E across C & E Brazil (NW Mato Grosso, E Amazonas and Pará) to Guyana, Suriname and French Guiana.

Descriptive notes. 17–18 cm; 24–42 g, mean 31–32 g. Male has head and entire upperparts including upperwing-coverts, flight-feathers and fairly long tail, glossy blue-black; throat and centre of chest black, white patch on side of chest bordered below by oblique black band from centre of chest to side of body; rest of underparts white, thighs black; iris dark brown; bill thick, bright red; legs brownish-grey to black. Female is similar to male but hindneck, back, rump and uppertail-coverts grey; oblique band on each side of breast often less distinct or mottled with white, and lower underparts often cream-coloured or tinged creamy cinnamon. Juvenile is distinctive, has bill black, head black (not glossy), upper back white, lower back black with white scaling and mottling, rump greyish-white, upperwing-coverts bluish-black with white tips, chin and underparts white, throat and chest white mixed with black, and thigh mixed black and white. Voice. Flocks sometimes quite vocal, giving fairly high-pitched, hard piercing calls, in fairly rapid succession, e.g. "éée-éèh...éée-éée-éèh...éée-éèh-yuu...", sometimes for extended periods of time. Song has similar penetrating nasal quality, a semi-musical but jumbled series of complex phrases and notes, reminiscent of song of an *Oryzoborus* seed-finch, or of a *Sporophila* seedeater delivered at brisk pace.
Habitat. Mainly high canopy and emergent trees of tall to very tall, humid *terra firme* forest, less often at forest borders; to c. 900 m.
Food and Feeding. Observed to feed on *Cecropia* catkins. Stomach contents included berries and seeds, also beetles (Coleoptera). Wide-ranging, and usually seen in groups of 3–8 individuals that forage high in canopy and in crown of emergent trees; pairs and groups occasionally descend to middle levels or lower at forest borders. Groups may associate with mixed-species flocks, mainly those containing other tanagers, honeycreepers and other species of canopy and emergent trees, but seem not to forage for extended periods of time with them; also encountered independently of mixed flocks. Will forage with other species at fruiting trees. Groups often leave a fruiting tree or high foraging site and fly long distance over top of canopy, calling, only to return a short time later. Foraging territories of groups seem quite large, perhaps 2–3 times as big as that of the mixed flock with which associated. In Suriname and elsewhere, perches horizontally, often on fairly large open branches (8–10 cm in diameter). Forages by hopping mostly along open branches and peering downwards to inspect sides of branch; reported also as leaping back and forth among larger open limbs in crown of tall tree, opening wings only once or twice to cover distance of c. 3–6 m, possibly capturing insects in air.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon. Occurs at low density, in part because of large foraging territories. Requires mature *terra firme* forest. Has reasonably large range, and no obvious threats.
Bibliography. Burns (1997a), Burns *et al.* (2002, 2003), Haverschmidt (1948, 1968), Haverschmidt & Mees (1994), Hilty (2009b), Marantz & Zimmer (2006), Munn (1985), Naumburg (1930), Oren & Parker (1997), Pacheco *et al.* (2007), Pearson (1975a), Pelzeln (1869), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Sick (1985, 1993), Snyder (1966), Souza (2002), Willis (1977), Yuri & Mindell (2002), Zimmer (1947b).



Genus *COMPSOTHRAUPIS* Richmond, 1915

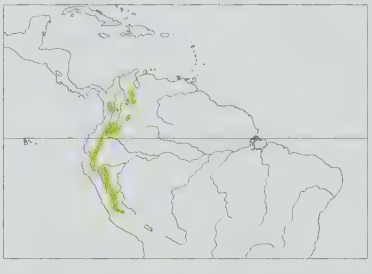
9. Scarlet-throated Tanager

Compsothraupis loricata

French: Tangara à gorge écarlate **German**: Rotbrusttangare **Spanish**: Tangara Gorjirroja

Taxonomy. *Tanagra loricata* M. H. C. Lichtenstein, 1819, NE Brazil (possibly Ceará).
Sometimes placed in genus *Sericossypha*, which it closely resembles in size, plumage and certain external morphological characters (e.g. tarsal scutellation, rounded non-operculate nostrils, weak rictal bristles, and bill shape); differs, however, primarily in having nostrils exposed (not covered). Retained in its own monotypic genus pending molecular data, but argument for maintaining this seems weak; behaviour suggests a sluggish *Thraupis* tanager, and many observers have remarked that it appears remarkably icterid-like in field. Monotypic.
Distribution. E Brazil from E Maranhão, Piauí, Ceará, Pernambuco and Alagoas S to WC Goiás and N Minas Gerais.

Descriptive notes. 21 cm; one male 72·5 g. Large, long-tailed and icterid-like in appearance. Male is glossy blue-black, except for scarlet throat and centre of chest; base of feathers of back and flanks white (not visible in field); bare black circumorbital area extends somewhat behind eye; iris dark brown; bill fairly stout, black; legs strong, dusky grey. Female is similar to male, but entire plumage, including throat and chest, black. Subadult male is like female, but duller. Voice. Call a loud icterid-like "chirt" or "kyuh", often repeated over and over (especially when in flight). Dawn song essentially a more ringing version of this same note, a single penetrating "kyeh" or "kyuh" repeated at intervals of c. 1 second, with only infrequent short pauses, sometimes for up to 45 minutes at dawn, rarely during day.
Habitat. *Caatinga*, gallery woodland and other semi-open areas near marshes, lagoons and rivers, generally not far from water; at 200–1000 m.
Food and Feeding. Stomach contents insects. Found in pairs, trios or, more often, small groups of up to c. 6–8 individuals, even when nesting; red-throated males usually greatly outnumbered by females, although flocks usually have at least one adult male. Sometimes seen in company of various icterids. Conspicuous, rather slow-moving and sometimes unwary. May perch on high exposed branch for extended periods.
Breeding. In display, male reveals white feather bases on back. Nest hidden in dense palm crown, in woodpecker (Picidae) hole in *Mauritia* palm snag, or in (or perhaps on top of) old stick nest of Caatinga Cacholote (*Pseudoseisura cristata*), carrying long sticks to add to nest. Seen to attack hawk (Accipitridae) near nest. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon. Extensive deforestation continues within the rather small range of this species, and its remaining suitable habitat is fragmented. In need of monitoring.
Bibliography. Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Pinto (1954), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Sick (1985, 1993), Souza (2002), Zimmer (1947b).



Genus *SERICOSSYPHA* Lesson, 1844

10. White-capped Tanager

Sericossypha albocristata

French: Tangara à coiffe blanche **German**: Weißkappentangare **Spanish**: Tangara Coroniblanca

Taxonomy. *Tanagra* (*Lamprotes*) *albo-cristatus* Lafresnaye, 1843, Colombia.
Despite numerous earlier suggestions to the contrary, morphological and genetic data support placement of this species within present family. Molecular-genetic data indicate that present genus and *Nemosia* are probably sister-taxa. Monotypic.
Distribution. SW Venezuela (Andes of S Táchira); and Colombia locally in E Andes (Norte de Santander), locally on both slopes of C Andes (Caldas–Tolima border), W Andes in Antioquia (La Linda, near city of Jardín) and head of Magdalena Valley in Huila S through Cauca and Nariño to Ecuador and C Peru (Junín).

Descriptive notes. 23–24 cm; 95–125 g. Large, with fairly stout bill small for size of bird; icterid-like in appearance. Male is mainly glossy blue-black with conspicuous plush-like white feathering on lores and forecrown extending to mid-crown; throat and chest rich crimson; iris dark brown; bill blackish; legs strong, dusky grey. Female is similar to male, but throat and chest dark dusky crimson, considerably darker and less conspicuous than that of male. Immature has white crown, but rest of plumage entirely matt black. Voice. Typically noisy, and heard well before seen. Gives loud, piercing "péééèaap!", sometimes followed by 1 or 2 shrieking "kéép" notes; also "kip" and "peeer", and "peeeur", irregularly or up to 40 notes per minute, at least some of which are doubtless contact notes to keep wide-ranging and rapid-moving flock-members together. Also gives same note or notes from perch, sometimes for lengthy period (up to 9 minutes recorded), turning from side to side or leaning forward with each note, but not changing perch.
Habitat. Humid and wet montane forest, especially mossy higher-elevation forest; less often along forest borders or tall second growth. Recorded at 1600–3200 m in Colombia, c. 1750–3000 in Ecuador (sight records to 1400 m), and c. 1700–2800 m in Peru; everywhere most numerous c. 1900–2700 m.
Food and Feeding. Of seven stomachs examined, two contained only vegetable matter, four only animal matter, and one both; contents included fruit pulp, seeds, ants, wasps and bees (Hymenoptera), beetles (Coleoptera), dipteran larvae, and a snail (Pulmonata) shell. Surprisingly few field observations of prey captures or food items taken; has been seen to eat *Cecropia* catkins, and some evidence in E Ecuador suggests that larvae of paper wasps (Vespidae) may be an important dietary item. Forages and travels in wide-ranging, wandering groups of 4–8 and occasionally up to 20 individuals; in Peru groups typically contain only one adult male, suggesting that some are family groups. Usually not with mixed-species flocks, although occasionally loosely associated with jays (Corvidae) or mountain caciques (*Cacicus*). Forages mostly in upper levels or canopy of trees, occasionally in tops of bushes and smaller trees at forest borders. Flock-members usually remain fairly close together, peer, posture and cock tail in jay-like fashion, and hop and leap boldly up through trees. Members of group often forage in two or three trees within a small area and then all fly off, some straggling along, to a new site, either nearby or up to hundreds of metres away, suggesting that foraging or home ranges are very large. Has been noted as sailing down slopes with wings open.
Breeding. One nest found, on E slope of Andes in Ecuador (between Baeza and Cosanga, at 2000 m): rather large, weakly constructed cup of rootlets and pale fibres, hidden by fronds; up to four

adults (three males, one female) brought food, possibly wasp larvae, up to three adults arriving simultaneously in nearby tree, but visiting nest singly; one nestling fledged on c. 22nd Jan. No other information.
Movements. May wander seasonally; in S Colombia, noted only Jan to late Apr and in Jun in Cueva de los Guácharos National Park.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common; declining. Deforestation and fragmentation of forest within its high-Andean range represent a significant threat, because groups require fairly large tracts of montane forest for foraging. Occurs in several larger protected areas, among them Tamá, Cueva de los Guácharos and Puracé National Parks (Colombia), Podocarpus National Park (Ecuador) and Tingo María National Park (Peru).

Genus *NEMOSIA* Vieillot, 1816

11. Hooded Tanager

Nemosia pileata

French: Tangara coiffe-noire **German**: Schwarzkappentangare **Spanish**: Tangara Encapuchada

Taxonomy. *Tanagra pileata* Boddaert, 1783, Cayenne, French Guiana.
Molecular-genetic data indicate that present genus and *Sericossypha* are probably sister-taxa. Six subspecies recognized.
Subspecies and Distribution.
N. p. hypoleuca Todd, 1916 – NW Colombia (Córdoba E in coastal region to Magdalena and S in Magdalena Valley to S Cesar) and N Venezuela (Zulia and Lara E to Distrito Federal, Delta Amacuro and N Bolívar).
N. p. surinamensis J. T. Zimmer, 1947 – Guyana and Suriname.
N. p. pileata (Boddaert, 1783) – French Guiana and WC Brazil (S of R Amazon between R Madeira and R Tapajós) S to extreme N Bolivia.
N. p. interna J. T. Zimmer, 1947 – CN Brazil in lower R Negro and upper R Branco regions.
N. p. nana Berlepsch, 1912 – NE Peru and W Brazil (E to lower R Madeira).
N. p. caerulea (Wied, 1831) – E & S Brazil (S of R Amazon and E of R Tapajós), and extreme SE Peru E to E Bolivia, Paraguay and NW & NE Argentina.

Descriptive notes. 12 cm; 12–22 g. Male nominate race has crown and side of head black, this extending down onto side of neck and narrowly to side of chest; upper lores (from top of bill to top of eye) pure white; nape and entire upperparts light porcelain-blue, tail dull porcelain-blue; lesser and median upperwing-coverts pale porcelain-blue (like back), greater coverts pale porcelain-blue and rather broadly edged dull white, primary coverts blackish; flight-feathers blackish, edged light grey-blue, tips of primaries blackish, tertials light grey-blue, inner webs fading to dusky; throat and underparts white, tinge of pale bluish to lavender-grey on breast, belly and sides; iris yellow; bill fairly heavy, all black; legs orange-yellow. Female is similar to male but duller blue, has crown, side of head and neck dull blue like upperparts (no black on head, neck or chest), lower mandible pale yellowish, legs duller yellow. Immature male resembles female, and may be sexually mature in this plumage. Races differ mainly in size and in plumage tones: *hypoleuca* is similar in size to nominate, but underparts entirely immaculate white; *surinamensis* is larger than nominate, and relatively darker above; *nana* differs from nominate in smaller size and overall darker coloration; *interna* is similar in coloration to nominate but smaller (thus similar in size to previous, but with paler upperparts); *caerulea* is largest and has palest upperparts of all races. Voice. Dawn song a high, insistent "tsip-tsip ti-chéw ti-chéw" or variant. Calls high-pitched, lisping "tic" and "sip" notes; when excited "tic, tic-ttttttttttttttttt", and other chips and trills.
Habitat. Moist deciduous and humid evergreen woodland, mostly in semi-open situations, pastures with scattered open trees, along woodland borders, and in irregular second growth, often in vicinity of water; may occur also at edge of mangroves. In vast Amazonian range mainly restricted to lighter *várzea* woodland and borders and in early to middle successional vegetation, especially on river islands and along riverbanks, where often seen in *Cecropia* trees. Lowlands to c. 600 m, locally to 1300 m.
Food and Feeding. Insects, infrequently fruit; reported to eat *Miconia* berries. Four stomachs contained only animal matter, including beetles (Coleoptera), hymenopterans (including ants and bees), bugs (Hemiptera, including homopterans), caterpillars, and spiders (Araneae). Found in pairs, families, or groups of up to half a dozen, which forage in single-species groups or, occasionally, in loose association with other species. Stays mostly on rather substantial open, upper branches (much less on twigs) within open trees, where it hops along rather deliberately, almost like a vireo (Vireonidae), peering at bark surfaces or leaf petioles and gleaning and picking insects. Often attracted to flowering trees, whether for nectar or for insects not determined; occasionally gleans or hovers around leaves. Most often seen in *Cecropia* and Leguminosae trees, where group attracts attention with occasional outbursts of chipping and twittering.
Breeding. In the Guianan region breeding may occur during short dry season (Feb/Mar–Apr) and again during longer Aug–Dec dry season, indicating either a bimodal pattern or a protracted season, occurring in most of year except during wettest months: in Suriname, nest-building observed Jul and Aug, occupied nest found in Dec, and fledglings recorded Oct and Feb; in French Guiana, two nests being built in Feb and pair feeding a juvenile in Mar; fledgling observed in Oct in E Venezuela. Nest built by both sexes, in French Guiana and Suriname a thin open cup constructed from dry weeds, tendrils, dead leaves, grass and spider webs, appears fragile; placed c. 8–12 m up in relatively open branch fork, usually exposed to partial or full sun, sometimes in isolated tree in clearing and somewhat away from forest. Clutch 2 eggs, bluish, spotted with brown or lilac-grey; no information on incubation and nestling periods.
Movements. Resident over most of range. Some seasonal movements may occur in *llanos* region of Colombia and Venezuela; seasonal movements possible in extreme S of range in S Brazil, Paraguay and N Argentina.
Status and Conservation. Not globally threatened. Fairly common throughout its large range; often locally distributed and seldom numerous. Found in a few protected areas, but much more widely in unprotected and partly disturbed areas. Because this species favours forest edge and semi-open situations, it may benefit locally from partial deforestation and opening of formerly forested areas; examples of partially cleared areas where this species occurs include ranchland at S end of L Maracaibo, in W Venezuela, and ranchland S of Tumeremo, in E Venezuela, and abandoned citrus plantations near Meerzog (Paramaribo), in Suriname; also regular in young second growth (i.e. *Cecropia*) on Amazonian river islands in NE Peru. Overall, seems to be at little risk in the short term, although populations of extreme E Brazil are almost certainly declining because of deforestation.
Bibliography. Belton (1985), Burns (1997a), Burns *et al.* (2002, 2003), Dugand (1947), Estela *et al.* (2000), Friedmann & Smith (1950), Haverschmidt (1948, 1952, 1968), Haverschmidt & Mees (1994), Hellmayr (1910), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Narosky & Di Giacomo (1993), Naumburg (1930), Pacheco *et al.* (2007), Parker & Goerck (1997), de la Peña & Rumboll (1998), Penard & Penard (1910), Phelps & Phelps (1963), Renaudier *et al.* (2008), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schäfer & Phelps (1954), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sick (1985, 1993), Snethlage, E. (1914), Snethlage, H. (1927, 1928a, 1928b), Snyder (1966), Souza (2002), Thomas (1982), Todd & Carriker (1922), Tostain *et al.* (1992), Zimmer (1947a).

12. Cherry-throated Tanager

Nemosia rourei

French: Tangara rougegorge **German**: Rubinkehltangare **Spanish**: Tangara Golirroja

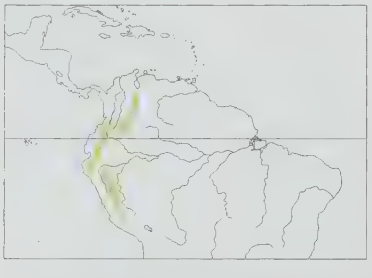
Taxonomy. *Nemosia Rourei* Cabanis, 1870, locality uncertain, probably Rio de Janeiro, Brazil.
Type locality was for long regarded as Muriaé, in SE Minas Gerais, but this now questioned, and hypothesized that type specimen is, in fact, from Macaé, in S Rio de Janeiro. Molecular-genetic data indicate that present genus and *Sericossypha* are probably sister-taxa. Although this species has for long been placed in present genus, it is vocally closer to *Lamprospiza*. Monotypic.
Distribution. Espírito Santo and probably also adjacent Minas Gerais, in E Brazil.

Descriptive notes. 12·5–14 cm; 22 g. Has crown pale pearl-grey with some white at margins, contrasting strongly with broad black mask across forehead and extending back through eye to nape; rest of upperparts bluish pearl-grey becoming paler again on rump and uppertail-coverts; wings black with outer edges of tertials mostly whitish-grey, tail black; throat and chest scarlet, this colour extending down to a point on upper breast (size and position of patch apparently somewhat variable), rest of underparts white except for a little black on rear of thigh; iris amber-yellow to deep amber; bill blackish; legs pinkish-grey to pinkish-flesh. Sexes apparently similar. Presumed immature has throat patch tinged brownish. Voice. Almost always noted first by voice. Call a loud, sharp, penetrating and somewhat nasal "péuuu, péuuu-see'ee", last 2 notes very high-pitched and uttered quickly; or almost any of above notes singly, doubled or in various combinations, e.g. "péuuu", or "péuuu, péuuu-see'se-péuuu", and so on. Also weaker, high-pitched "ti" notes, singly or in longer series, sometimes in rapid series. Song not certainly known, but has been suggested that loud penetrating vocalizations described above represent a song.
Habitat. Dense humid hill forest and forest borders ("Atlantic Dense *Ombrophyllous* Montane Forest"), especially with tall trees, extensive epiphytic growth, and palms (of genus *Euterpe*). Sporadic observations in coffee plantations, eucalypts (*Eucalyptus*) and pines (*Pinus*) seem to be related to movements between more suitable forest patches. Recorded at c. 850–1250 m.
Food and Feeding. Recorded food items include caterpillars, a butterfly (Lepidoptera), an ant (Formicidae) and other small arthropods; has been seen to forage in eucalypt flowers. Most recent observations have been of birds travelling in wide-ranging, monospecific groups of 2–8 individuals; occasionally singles seen, with groups of 2–3 the norm. Less often (c. 35% of time) found with or near mixed-species flocks in canopy and upper levels of humid forest. Sirystes (*Sirystes sibilator*) being a frequent flock associate, as is Chestnut-crowned Becard (*Pachyramphus castaneus*) and *Hemithraupis ruficapilla*; larger flocks in which present species seen appear always to contain other tanagers, as well as woodpeckers (Picidae), woodcreepers (Dendrocolaptidae), ovenbirds (Furnariidae), tyrant-flycatchers (Tyrannidae) and cotingas (Cotingidae). Extremely low rate at which groups are encountered suggests that these birds have large home ranges. Forages by hopping along branches and peering first on one side and then on the other, and by gleaning from leaves. One individual which captured a large lepidopteran was pursued by *Thraupis ornata*; another was attacked unsuccessfully by a Black-necked Araçari (*Pteroglossus aracari*).
Breeding. Nest-building observed once, on 25th Nov: two birds bringing moss to a shallow natural depression at base of medium-height branch adjacent to a main trunk, third individual present but did not bring material, and fourth individual nearby seen to carry small twig; not observed to bring any other nest material. In possible courtship display in Oct, one individual (probably male) faced another on a high branch, held wings half-open, perpendicular to body, and weakly fluttered them while slightly raising head and calling quietly. No other information. Recorded longevity more than 6 years.
Movements. No information.
Status and Conservation. CRITICALLY ENDANGERED. Restricted-range species: present in Atlantic Forest Lowlands EBA. Rare, declining and poorly known. Global population assessed at fewer than 250 individuals within total estimated range of c. 31 km². Until a 1998 sighting, and a scattering of more recent sightings, the species had not been positively seen in more than fifty years and was feared extinct. Rediscovered in 1998 in mountains of Conceição do Castelo (20°19' S, 41°17' W) at privately owned Fazenda Pindobas IV, in S Espírito Santo, and subsequently seen there by a number of observers; in 2003–2004 reported in Espírito Santo from Mata do Caetés, at c. 1100–1250 m in Vargem Alta municipality, where up to eight individuals have been seen; probable sighting also at Fazenda Pedra Bonita, in Minas Gerais, but recent surveys failed to confirm this report. Other sites with "probable" records are being investigated. Rio de Janeiro National Museum reportedly once held two additional specimens, both subsequently lost. Still threatened with extinction, this enigmatic bird is known from only a handful of sites and is not reliably found at any of them. At present only two groups definitely known, a group of about six at Pindobas IV

and the other of at least eight at Caetés, both sites in Espírito Santo montane forest. Recent observations suggest that a small population exists also at Augusto Ruschi Biological Reserve. Small number of records, despite intensive searches, doubtless reflects the species' extreme rarity, and now, as a result of massive deforestation, it is very patchily distributed, being confined to only a few small, isolated reserves. During a recent year of fieldwork devoted to assessing its status and ecology, only eleven records were obtained. Intensive biological surveys in Espírito Santo and Minas Gerais continue. Present population estimates range from minimum of 14 known individuals to estimated maximum of c. 250. The major threat to this species is forest destruction, which continues, and consequent fragmentation of habitat. Associated threats include quarrying for limestone, granite and marble (including use of explosives), illegal palm extraction, expansion of coffee plantations, small-scale firewood-cutting, and larger-scale timber-cutting, including for charcoal production. In 2010, the government of the state of Espírito Santo signed a decree that will help to save this species, one of the rarest birds in Brazil. This decree recognizes ten "Ecological Corridors" as priority areas for conservation of Espírito Santo's biodiversity: these are Saíra-apunhalada, Córrego do Veado, Pedra do Elefante, Sooretama–Comboios–Goytacazes, Alto Misterioso, Centro Norte Serrano, Duas Bocas–Mestre Álvaro, Guanandy, Bururama–Pacotuba–Cafundó, and Caparaó. The objective is to reconnect Atlantic Forest remnants by developing forest conservation and restoration actions, and promoting sustainable activities and proper soil management. This species has been adopted as the symbol of the region, thereby raising its profile and contributing to campaigns for the conservation of its forests.

Bibliography. Anon. (2010a), Bauer, Pacheco, Venturini, Paz *et al.* (1998), Bauer, Pacheco, Venturini & Whitney (2000), Butchart & Stattersfield (2004), Isler & Isler (1999), Jacomelli (2008), Pacheco (1998, 1999), Ridgely & Tudor (1989, 2009), Scott (1997), Scott & Brooke (1985), Sick (1979, 1985, 1993, 1997), Sick & Teixeira (1979), Souza (2002), Stattersfield & Capper (2000), Venturini & Rehen (2000), Venturini, Rehen *et al.* (2000, 2001), Venturini, Rogerio de Paz & Kirwan (2002, 2005).

Genus *CREURGOPS* P. L. Sclater, 1858



13. Rufous-crested Tanager

Creurgops verticalis

French: Tangara à cimier roux **German**: Ockerschopftangare **Spanish**: Tangara Crestirrufa

Taxonomy. *Creurgops verticalis* P. L. Sclater, 1858, Rio Napo, eastern Ecuador.
Forms a superspecies with *C. dentatus*. Monotypic.

Distribution. W Venezuela (Táchira), and Andes from Colombia (patchily W & C Andes, including both slopes in Nariño, head of Magdalena Valley in Huila; spottily on entire E slope of E Andes) S on W slope to extreme NW Ecuador (Carchi), and throughout E slope of Ecuador S to C Peru (Junín and N Ayacucho).

Descriptive notes. 15 cm; 21–27 g. Notably heavy bill has small "tooth" near tip of cutting edge of upper mandible, visible in the hand. Male has crown and side of head to below eye leaden grey, with broad cinnamon-rufous crest narrowly bordered black (crest usually held flat); nape and upperparts, including upperwing-coverts, uppertail-coverts and tail, leaden grey; flight-feathers dusky, edged leaden grey, tertials mostly leaden with dusky inner webs; chin, throat and entire underparts to undertail-coverts cinnamon-rufous; iris dark red to reddish-brown; bill stout, blackish; legs brownish-grey. Female is similar to male, but lacks rufous crest and has underparts slightly paler. Immature male is like female, but grey of upperparts mixed with buff, crown patch usually undeveloped. Voice. Often rather quiet. Song (or possibly calls) a rather high series of short phrases, "pit-sa, pit-sa...sa-pit, sa-pit, sa-pit...sa-pit...pit-za", without much clear pattern. Calls include lower-pitched "chup" notes and various undistinctive "sit" and "seet" notes.

Habitat. Humid and wet mossy montane forest, and occasionally along forest borders; primarily a cloudforest species. At 1600–2700 m in Colombia, 1500–2800 m in Ecuador, and 1100–2400 m in Peru; recorded at c. 1800 m in Venezuela.

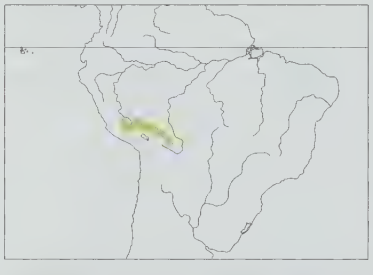
Food and Feeding. Primarily an insectivorous species; eats some fruit. One stomach contained only animal matter, another both vegetable and animal matter, including fruit pulp and insects. Usually in pairs, associated with mixed-species flocks containing New World warblers (Parulidae), and *Conirostrum* and other tanagers. Hops along bare or mossy limbs in canopy or subcanopy, and works out into terminal foliage, where it probes, pecks and reaches out or up, or hangs downward to glean insects from leaves. May opportunistically sally or flutter short distances to air. Fairly active and energetic, but not so restless as smaller *Hemispingus* and *Tangara*.

Breeding. In Colombia, two males in breeding condition in Jun at N end of W Andes and, in C Andes, one in Jun in Antioquia and one in Mar in S Huila; juvenile in Aug in Huila, another in Dec in E Nariño. No other information.

Movements. None recorded.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. In Venezuela, known only from a few records near Colombian border. Deforestation within this species' range is widespread, especially in Colombia and Ecuador, but it occurs in numerous protected areas, including Tamá National Park (Venezuela), and Las Orquídeas, Tatamá, Farallones de Cali and probably Cueva de los Guácharos National Parks (Colombia), as well as the Río Blanco Reserve, in Caldas (Colombia), also Cayambe-Coca Ecological Reserve and Sangay, Podocarpus and Sumaco-Galeras (and other) National Parks, on Ecuador's E slope, and Cordillera de Colán and Tingo María National Parks, in Peru. Despite fragmentation of its range through deforestation, it should survive also in intact habitat in many unprotected areas.

Bibliography. Burns & Racicot (2009), Burns *et al.* (2003), Echeverry-Galvis & Córdoba-Córdoba (2007), Fjeldså & Krabbe (1990), Graves (1983), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Lysinger *et al.* (2005), Remsen *et al.* (2010), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schulenberg *et al.* (2007), Zimmer (1947a).



14. Slaty Tanager

Creurgops dentatus

French: Tangara ardoisé **German**: Schiefertangare **Spanish**: Tangara Pizarrosa

Taxonomy. *Malacothraupis dentata* P. L. Sclater and Salvin, 1876, Tilotilo, La Paz, Bolivia.
Was earlier placed in a separate genus, *Malacothraupis*. Forms a superspecies with *C. verticalis*. Monotypic.

Distribution. E slope of Andes from SE Peru (Cordillera Vilcabamba, in Cuzco) S to Bolivia (Cochabamba, possibly also Santa Cruz).

Descriptive notes. 14 cm; 16–20 g. Male has conspicuous chestnut cap extending from bill to nape, bordered narrowly with black at side; otherwise, plumage almost entirely slate-grey above and below, including wing-coverts, flight-feathers and tail; iris reddish-brown; bill strong, blackish; legs greyish-horn. Female is rather different, with dark grey crown bordered by long, narrow white supercilium, and dark grey lores and area back through eye; chin and upper throat white, merging into bright rufous on side of neck, chest, breast and sides and flanks, with centre of lower breast, belly and undertail-coverts white. Immature and subadult resemble female, but much duller, underparts mottled dingy greyish-white, with rufous tinge on breast. Voice. Calls during foraging a rather rough, burry "zurrk" and various high-pitched "sik" and "seet" notes, much like those of many other tanagers. No song yet recorded.

Habitat. Humid and wet montane forest and tall, humid second growth; primarily a cloudforest bird. Recorded at 1200–2500 m.

Food and Feeding. Arthropods, relatively little fruit. Contents of five stomachs were insects, including beetles (Coleoptera). Normally found singly or in pairs, foraging with mixed-species flocks containing other tanagers, especially *Tangara*. Forages mainly in upper part of trees; on steep, broken forest hillsides also regularly found in shrubs or lower woody vegetation, as well as in canopy or subcanopy of higher mossy trees. Fairly active and restless, working along smaller bare and mossy limbs; often spends considerable time in peering and moving in outer foliage, where it pops in and out of view.

Breeding. No information.

Movements. Some local or seasonal movement possible; only occasionally recorded in disturbed forest along R Urubamba below Machu Picchu, in Peru.

Status and Conservation. Not globally threatened. Restricted-range species: present in Peruvian East Andean Foothills EBA and Bolivian and Peruvian Lower Yungas EBA. Fairly common in S Peru (Cuzco and Puno); status in Bolivia less clear. Deforestation of middle-elevation montane forest will affect this species locally. On the other hand, it occurs in several large protected areas, including Manu National Park, in Peru, and Madidi National Park, in Bolivia. The species' range includes considerable intact forest which is unprotected, but appears not to be at any risk in the short term.

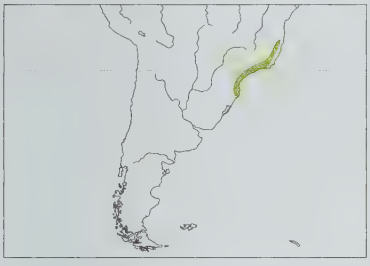
PLATE 2



Genus *ORTHOGONYS* Strickland, 1844

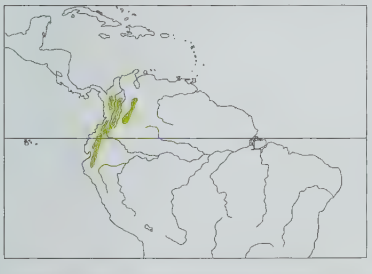
15. Olive-green Tanager

Orthogonys chloricterus

French: Tangara viréon **German**: Olivtangare **Spanish**: Tangara Verdioliva

Taxonomy. *Tachyphonus chloricterus* Vieillot, 1819, near Rio de Janeiro, Brazil.
Monotypic.
Distribution. Espírito Santo S to E Santa Catarina, in SE Brazil.

Descriptive notes. 18–19 cm. Olive and yellow tanager lacking distinctive markings, with bill relatively slender. Plumage is uniformly olive above, including wing and tail, slightly darker on crown; below, entirely dull yellow (contrasting with olive upperparts), with tinge of olive on sides and flanks; iris dark brown; bill blackish; legs pale yellowish-brown, sometimes with pinkish tinge. Sexes similar. Juvenile undescribed. Voice. Loud "wheek!" and other notes during foraging, often heard well before groups appear in view; call a high, buzzy "tseee". Song a chattery, bubbly mix of "tseee" and "pit" or "si" notes, often 3–5 in a series, followed by short pause, e.g. "tséé-si, si, si, tséé-si, si, si", sometimes several individuals joining in and singing simultaneously.
Habitat. Tall humid montane forest and forest borders in coastal mountains, at 900–1800 m.
Food and Feeding. Insects; some fruit, including *Cecropia* catkins. Occurs in flocks of about eight individuals, occasionally up to 20, most often in single-species flocks. When foraging, individuals within group often spread over fairly large area. Forages mainly in middle and upper levels, but may come lower, especially for fruit. Hops along branch, then pauses to peer at foliage and bromeliads, often stretching upwards. In sample of c. 60 observations, most were of birds taking insects from leaves, including large leaves, and from bromeliads; smaller number were of sallies for flying insect prey. Sometimes comes to fruit feeders. Flicks tail up when excited.
Breeding. Bird carrying nest material to bromeliad on large tree in Nov. No other information.
Movements. None reported.
Status and Conservation. Not globally threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Locally common to uncommon. Despite some published statements, no definite records from Rio Grande do Sul. Occurs in numerous parks and reserves in SE Brazil. Numerous at Boraceia Forest Reserve, in Serra do Mar (NE São Paulo); smaller numbers at Itatiaia and Tijuca National Parks (Rio de Janeiro). Outside protected areas and parks, almost all habitat formerly occupied by this species has disappeared, resulting in range contractions and highly fragmented distribution. Despite local population declines and fragmentation, its long-term viability should be assured if protection continues for the parks and reserves where it remains.
Bibliography. Davis (1945b, 1946), Diamond & Lovejoy (1985), Goeldi (1894), Holt (1928), Isler & Isler (1999), Machado (2002), Parker & Goerck (1997), Ridgely & Tudor (1989, 2009), Santos (1948), Sick (1985, 1993), Souza (2002).



Genus *HEMISPINGUS* Cabanis, 1851

16. Black-capped Hemispingus

Hemispingus atropileus

French: Tangara à calotte noire **Spanish**: Hemispingo Capirotado
German: Schwarzkappenhemispingus
Other common names: Black-capped Tanager(!)

Taxonomy. *Arremon atro-pileus* Lafresnaye, 1842, Bolivia; error = Bogotá, Colombia.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. This species may form a superspecies with *H. auricularis* and *H. calophrys*, and has been treated as conspecific with one or both of those; currently treated as separate species to emphasize plumage differences, pending additional study. Monotypic.
Distribution. W Venezuela (Andes in S Táchira) and generally in Andes of Colombia and on both slopes in Ecuador S to extreme NW Peru (N Piura N of R Marañón).

Descriptive notes. 16 cm; 18–26 g. Bill moderately stout, but thinner than that of most other tanagers. Has crown and side of head sooty black, long, narrow buff-white supercilium from nostril to nape; upperparts, including tail-coverts, brownish-olive; lesser and median upperwing-coverts olive, greater coverts dusky, tinged olive; flight-feathers dusky, edged olive-yellow, tertials dusky, broadly edged olive-yellow; tail mostly dull greyish-olive; throat and foreneck rather bright ochre-yellow, this becoming duller on mid-breast, more olive-yellow on central lower underparts; sides, flanks and undertail-coverts mostly olive; iris reddish-brown; bill variable, all dusky or upper mandible dusky, lower mandible bluish-grey; legs horn-grey, tinged olive. Sexes similar. Immature resembles adult, but duller. Voice. Infrequently heard song a fast series of high sputtering and chipping notes, rather indistinctive and not so explosive as that of some congeners. Contact calls include "tsit" and other high-pitched notes and chatters.
Habitat. Humid and wet montane forest, especially (or mainly) where *Chusquea* bamboo and other dense vegetation dominant; also elfin forest near tree-line. Recorded at 1800–3600 m: mostly above c. 2400 m in Colombia; mostly at 2250–3200 m in Ecuador and adjacent N Peru.
Food and Feeding. Small arthropods. Forages in pairs or in groups of 3–7, occasionally up to 12 individuals, and in single-species groups or, far more frequently, in mixed flocks with *Basileuterus* warblers and other small tanagers. May behave as leader in small mixed flocks. Group fast-moving, active and warbler-like; primarily gleans or picks small arthropods from foliage, bamboo stems and leaves, mainly from near ground to c. 6 m up. Not shy, but can be difficult to see well because of dense lower vegetation in which usually found.
Breeding. No information.
Movements. None reported.
Status and Conservation. Not globally threatened. Locally common. In Colombia, commonest at higher elevations within its range. Extensive deforestation, especially at higher elevations, may be a local threat to this species.
Bibliography. Burns (1997a), Burns & Racicot (2009), Burns *et al.* (2002, 2003), Clements & Shany (2001), Dunning (1982), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (2003), García-Moreno *et al.* (2001), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Klicka *et al.* (2007), Krabbe *et al.* (2001), Lovette & Bermingham (2002), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Zimmer (1947b).

17. White-browed Hemispingus

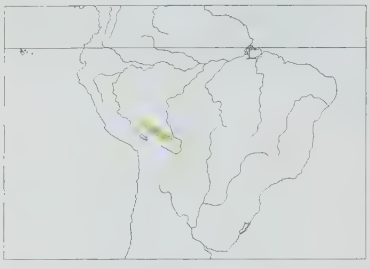
Hemispingus auricularis

French: Tangara oreillard **German**: Weißbrauenhemispingus **Spanish**: Hemispingo Cejiblanco
Other common names: Puno Hemispingus, White-browed Tanager

Taxonomy. *Chlorospingus* (*Hemispingus*) *auricularis* Cabanis, 1873, Marayniоc, Junín, Peru.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. This species may form a superspecies with *H. atropileus* and *H. calophrys*, and has been treated as conspecific with one or both of those; replaces former on S side of R Marañón, and currently treated as separate species on grounds of some plumage differences and molecular-genetic analyses. Monotypic.
Distribution. Peru on E slope of Andes (from Marañón Valley S to Cuzco).

Descriptive notes. 15–16 cm. Bill moderately stout, but thinner than that of most other tanagers. Has crown, side of head and broad band down side of neck black, long white supercilium from base of bill to nape; entire upperparts, including upperwing-coverts, bright olive; flight-feathers dusky, edged olive, tertials olive, inner web dusky; tail olive-green; throat and chest rich ochre-yellow (some individuals slightly paler), flanks yellowish-olive, central lower underparts pale yellow; iris dark reddish-brown; upper mandible dusky, lower mandible often paler horn-grey; legs horn-grey, tinged olive. Differs from *H. atropileus* in slightly smaller size, blacker face, whitish (not buff-white) supercilium, and usually deeper, richer ochraceous-yellow (not olive-yellow) underparts. Sexes similar. Juvenile undescribed. Voice. Dawn song, from exposed perch at top of tree 5–10 m tall, a slow, even series of 3–5 single thin "chew" notes alternated with 6–9 high "zeet" notes, e.g. repetitive "chew zeet, chew zeet, chew zeet...", reminiscent of hummingbird (Trochilidae) song; often continuously for 15–20 minutes. Perches upright, flicks tail continuously from side to side, looks back and forth, or flips around 180 degrees while singing.
Habitat. Humid and wet forest and forest borders, especially where *Chusquea* bamboo and dense undergrowth present; at c. 2600–3700 m.
Food and Feeding. Of 13 stomachs examined, one contained only vegetable matter, eleven only animal matter, and one both; contents included caterpillars and other insects, and seeds. Forages in pairs or in varying-sized groups, much as *H. atropileus*; often with mixed flocks containing other tanagers and, especially, *Basileuterus* warblers. Forages actively near ground, or in understorey. Often creeps and hops up bamboo stalks and branches, or jumps from one to the next, reaching and gleaning from beneath leaves or probing and pecking at bamboo internodes; less often, leans down to pick insect prey from upper surface of leaves.
Breeding. In Peru, cup-nest of leaves and stems; eggs pale rose with numerous reddish-grey spots and streaks, markings random or nearer large end. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common at higher elevations throughout range. Occurs in some protected areas, such as Manu National Park. Some portions of its range are subject to colonization pressure, which could place the species at risk locally in the future.
Bibliography. Clements & Shany (2001), Fjeldså & Krabbe (1990), García-Moreno *et al.* (2001), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (2009), Schulenberg *et al.* (2007), Taczanowski (1884), Walker (2001).

18. Orange-browed Hemispingus



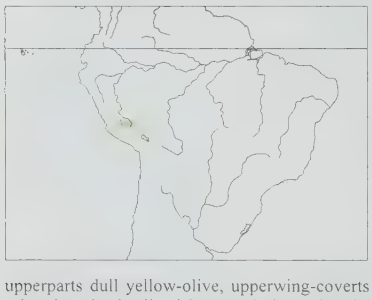
Hemispingus calophrys

French: Tangara des bambous **Spanish**: Hemispingo de los Bambúes
German: Ockerbrauenhemispingus
Other common names: Bolivian/Yungas Hemispingus, Orange-browed Tanager

Taxonomy. *Chlorospingus calophrys* P. L. Sclater and Salvin, 1876, Tilotilo, La Paz, Bolivia.

On following pages: 19. Parodi's Hemispingus (*Hemispingus parodii*); 20. Superciliaried Hemispingus (*Hemispingus superciliaris*); 21. Grey-capped Hemispingus (*Hemispingus reyi*); 22. Oleaginous Hemispingus (*Hemispingus frontalis*); 23. Black-eared Hemispingus (*Hemispingus melanotis*); 24. Piura Hemispingus (*Hemispingus piurae*); 25. Western Hemispingus (*Hemispingus ochraceus*); 26. Slaty-backed Hemispingus (*Hemispingus goeringi*); 27. Rufous-browed Hemispingus (*Hemispingus rufosuperciliaris*); 28. Black-headed Hemispingus (*Hemispingus verticalis*); 29. Drab Hemispingus (*Hemispingus xanthophthalmus*); 30. Three-striped Hemispingus (*Hemispingus trifasciatus*).

Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. This species may form a superspecies with *H. atropileus* and *H. auricularis*, and has been treated as conspecific with former or both. Possibly closest to *H. parodii*, which appears to be its sister-taxon. Monotypic.
Distribution. E slope of Andes in S Peru (S Puno) S to W & C Bolivia (La Paz and Cochabamba).



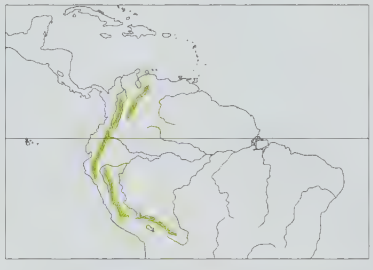
Descriptive notes. 14–16 cm; 14·5–20·5 g. Has central crownstripe and broad stripe through eye back to nape jet-black, small orange-ochre spot embedded in black on rear ear-coverts; long, broad supercilium bright orange-ochre; entire upperparts, including tail and upperwing-coverts, bright olive, tinged yellowish; primary coverts blackish, edged olive; flight-feathers dusky, outer feathers edged yellow, inner ones olive; side of head (below eye), throat and chest rich orange-ochre, fading to ochre-yellow on lower underparts; sides, flanks and undertail-coverts pale olive, faintly tinged yellowish; iris dark brown; bill dark grey, paler below; legs dark grey. Differs from *H. atropileus* and *H. auricularis* mainly in much broader and orange-ochre (not whitish) supercilium. Sexes similar. Immature is duller than adult, head mostly olive. Voice. During foraging, high chittery trills that descend somewhat (distinctive, but variable in length), sometimes given repeatedly by group-members; also a variety of high, soft "tic" and "ti" notes. No song yet recorded.
Habitat. Humid and wet montane forest and elfin forest, mainly where extensive *Chusquea* bamboo present; found also in dense regrowth vegetation around landslides. At 2300–3350 m.
Food and Feeding. Of 26 stomachs examined, 24 contained only animal matter and two both animal and vegetable matter; contents included caterpillars and other unidentified insects. Occurs in pairs or in small groups of about 4–8 individuals, foraging with mixed-species flocks or independently of them. In Bolivia found mainly in bamboo and fairly close to ground; median foraging height c. 3 m, no records above 6 m. Gleans prey from both surfaces of leaves equally (24 of 28 observations), also from slender branches 1 cm in diameter. Picked prey from substrates mostly without acrobatics (19 of 24 observations) or reached, hung or sallied. Occasionally probes hanging dead-leaf clusters. Behaviour much as that of *H. auricularis* and *H. atropileus*.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Bolivian and Peruvian Upper Yungas EBA. Fairly common to locally common. Has comparatively small range, within which it is likely vulnerable to ongoing colonization and deforestation.
Bibliography. Clements & Shany (2001), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (2003), Hellmayr (1936), Isler & Isler (1999), Lambert (2006), Meyer de Schauensee (1970a), Remsen & Parker (1984), Ridgely & Tudor (2009), Schulenberg *et al.* (2007), Weske & Terborgh (1974).

19. Parodi's Hemispingus

Hemispingus parodii

French: Tangara de Parodi **German**: Gelbbrauenhemispingus **Spanish**: Hemispingo de Parodi
Other common names: Parodi's Tanager

Taxonomy. *Hemispingus parodii* Weske and Terborgh, 1974, River Mapitunari, 3480 m, Cordillera Vilcabamba, Cuzco, Peru.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. Present species may be closest to and sister-taxon of *H. calophrys*. Appears to be upper-elevational replacement of *H. atropileus*. Monotypic.
Distribution. Vilcabamba and Vilcanota Cordilleras (E slope of Andes), in Cuzco, S Peru.



Descriptive notes. 14 cm; one male 21·8 g. A fairly large hemispingus very similar in appearance to Citrine Warbler (*Basileuterus luteoviridis*). Has top of head dusky olive, darker on forehead, lighter on rear crown, the feathers dull blackish with dark yellow edges; long narrow supercilium from base of upper mandible to nape yellowish, brightest over eye; lores and postocular region olive, ear-coverts and subocular area dull yellowish with paler shaft streaks; postauricular area dark citrine, bordered behind by dull yellowish band that extends upwards from side of throat and, along with supercilium, largely encloses side of head; upperparts dull yellow-olive, upperwing-coverts dark citrine (like back), flight-feathers dusky, primaries edged yellowish, secondaries and tertials dark citrine (like back); tail slightly graduated, outer webs of feathers dark citrine, inner webs dusky; chin and throat bright yellow (no ochre tinge), flanks and side of breast dull yellow, central breast and belly brighter, undertail-coverts paler yellow; iris dark brown; bill grey, upper mandible often duskier, cutting edges usually pale; legs pale grey. Differs from Citrine Warbler chiefly in having crown dusky olive (not yellowish), legs grey (not pinkish-flesh), and bill two-toned (not all black). Sexes similar. Immature undescribed. Voice. Dawn song a repetition of "pit zzre", first note high-pitched, second slightly lower. Day song a series of rapid, chittering and buzzy phrases, "p-p-p-psit-sit-sit, z-z-z-zit-dit-dit", and "zh-zh-zh-zhit-zhit-zhit", high-pitched. Abrupt shifts from one phrase to another at different pitch and tone are typical, occurring in a fraction of a second or sometimes with pause between song shifts.
Habitat. *Chusquea* bamboo in humid upper montane forest and elfin forest, and areas of mixed elfin forest and tall grass with irregular tree-line of short, gnarled trees heavily coated with epiphytes. At or near tree-line from 2750 m to c. 3500 m.
Food and Feeding. Arthropods. In groups of 3–9 individuals, usually in mixed flocks with Citrine Warbler and other small passerines. Forages low in bamboo and in mixed bamboo and leafy understorey. Gleans items from both surfaces of leaves and from bamboo leaves and internodes; may lean down or stretch to pluck prey off substrate.
Breeding. Birds in partial/full breeding condition suggest breeding from Jul. No other information.
Movements. No information; probably resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Bolivian and Peruvian Upper Yungas EBA. Fairly common locally. May occur at scattered locations in Manu National Park, but much of tree-line habitat within its range is unprotected and currently subject to disturbance from firewood-cutting and deforestation for subsistence agriculture and settlement. Populations should be monitored; may require listing as, at least, Near-threatened.
Bibliography. Clements & Shany (2001), Fjeldså & Krabbe (1990), Isler & Isler (1999), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Walker (2001), Weske & Terborgh (1974).

20. Superciliaried Hemispingus

Hemispingus superciliaris

French: Tangara bridé **German**: Augenbrauenhemispingus **Spanish**: Hemispingo Cejudo
Other common names: Superciliated Hemispingus, Superciliaried Tanager; Yellow-browed/Tachira Hemispingus (*chrysophrys*); White-browed Hemispingus ("*superciliaris* group"); White-bellied Hemispingus ("*leucogastrus* group")

Taxonomy. *Arremon superciliaris* Lafresnaye, 1840, Santa Fé de Bogotá, Colombia.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. Races form three groups, "*superciliaris* group" (including *chrysophrys*, *nigrifrons* and *maculifrons*), with yellow underparts, "*leucogastrus* group" (including *insignis*), with white underparts, and single-species "*urubambae* group", with yellow underparts, and no intergrades between groups found; alternatively, *chrysophrys* treated as separate, single-species group and *urubambae* as part of "*superciliaris* group". "Leap-frog" plumage pattern (yellow underparts in populations on each side of grey population), and supercilium yellow in far N and white elsewhere, are curious morphological differences, suggesting that more than one species involved; genetic analysis needed. Seven subspecies currently recognized.
Subspecies and Distribution.
H. s. chrysophrys (P. L. Sclater & Salvin, 1875) – Andes of Trujillo, Mérida and N Táchira, in W Venezuela.
H. s. superciliaris (Lafresnaye, 1840) – E Andes of Colombia (W slope in Santander, E slope in Boyacá, and both slopes in Cundinamarca).
H. s. nigrifrons (Lawrence, 1875) – C Andes in Colombia (from Antioquia S on both slopes through Cauca and Nariño) and Ecuador (S on W slope to Azuay and on E slope to Morona-Santiago).
H. s. maculifrons J. T. Zimmer, 1947 – W slope in S Ecuador (El Oro) S to N Peru (Cajamarca).
H. s. insignis J. T. Zimmer, 1947 – E slope of Andes in Peru (from Amazonas S to Junín).
H. s. leucogastrus (Taczanowski, 1874) – E slope of Andes in Junín (Peru).
H. s. urubambae J. T. Zimmer, 1947 – E slope of Andes in Peru (S from Cuzco) S to C Bolivia (Cochabamba).

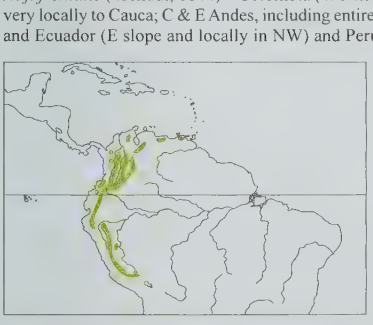
Descriptive notes. 13–14 cm; 11–17 g. Overall, rather variable. Nominate race has forecrown and cheek dusky, long narrow white supercilium; rest of crown, nape and upperparts, including tail and upperwing-coverts, olive-green, primary coverts blackish; flight-feathers blackish, outer primaries edged olive-yellow, inner ones olive-green; throat and underparts bright yellow, flanks tinged olive; iris reddish-brown; bill fairly small and slender, grey, sometimes duskier above and paler below; legs dark grey. Sexes similar. Immature (or subadult) is duller, with less contrasting head pattern, more olive on breast and sides. Race *chrysophrys* differs from nominate in having yellow (not white) supercilium, olive forecrown and duller cheek; *nigrifrons* is like nominate, but more dusky on forecrown and cheek; *maculifrons* differs in pale greyish-olive forecrown and cheek; *leucogastrus* is distinctive, crown, cheek and upperparts all grey, supercilium white, whitish below, some dusky mottling on side of throat, heavy grey tinge on breast, buff tinge on undertail-coverts; *insignis* is like last, but generally paler, with faint yellow tinge on undertail-coverts; *urubambae* is much like nominate but slightly paler below, forecrown blackish, eyestripe typically with traces of yellow towards rear. Voice. Song (races *maculifrons* and *leucogastrus*) primarily just after dawn, often as duet, trio or quartet, bursts 3–4 seconds long of rapid high notes, rather dry and harsh, that accelerate and become louder (cadence reminiscent of ocean waves rolling onshore), may be repeated at short intervals. Songs presumably similar throughout range (more information needed). Calls rather undistinctive high, sharp "tsit" or "tsick" notes.
Habitat. Humid forest and forest edges, also second growth of various ages, alder (*Alnus*) in landslides, and locally tall *Polylepis* woodland in Ecuador, Peru and Bolivia. Recorded at c. 1900–3350 m in all areas, mostly above c. 2100 m; in Ecuador, up to 3500 m at Yanacocha and to 3700 m at Loma Yanayacu; in Peru, mainly 2200–3450 m on E Andean slope and 2200–2900 m on W slope S to S Cajamarca.
Food and Feeding. Arthropods; may take some small berries and seeds. Twelve stomachs contained insects, including caterpillars and small beetles (Coleoptera). Forages in pairs and in noisy, chittering groups of 3–10 individuals, usually with mixed flocks; locally or seasonally groups of up to 20, sometimes more, in Cuzco (SE Peru), where joins with many other small passerines, including furnariids, tyrant-flycatchers (Tyrannidae), tanagers and emberizids, forming super-sized mixed flocks around dawn. Active and restless, peers and hops in foliage, mostly without acrobatics, but may reach up or out, lean over, or occasionally hang downwards to glean insects from top and bottom of live leaves. Sometimes forages out into rather open trees (alders), generally fairly easy to see. In Peru and Bolivia primarily in tops of trees 8–20 m tall, but descends to small trees, shrubs and bamboo along forest borders; forages higher than *H. atropileus*, but also down to human eye level or lower, especially along forest borders and roadsides, and mainly gleans from leaves in dense foliage near branch tips, often where leaf clusters join branches. From 34 observations in Bolivia, median foraging height 11 m, median distance to top of canopy c. 2 m, and prey gleaned in about equal proportions from top, bottom and base of leaves.
Breeding. Three breeding specimens between Feb and Jul in C Andes of Colombia. No other information.
Movements. Resident throughout range.
Status and Conservation. Not globally threatened. Fairly common to locally common. Increasing human colonization and wood-cutting at high elevations an ongoing concern, but this species should be able to survive in various older-age stages of second growth and forested borders.
Bibliography. Anon. (2000), David & Gosselin (2002a), Dunning (1982), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (2003), García-Moreno *et al.* (2001), Hellmayr (1936), Hilty (2003, 2009b), Hilty & Brown (1986), Isler & Isler (1999), Krabbe *et al.* (2001), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Phelps & Phelps (1963), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Walker (2001), Weske (1972), Zimmer (1947b).

21. Grey-capped Hemispingus

Hemispingus reyi

French: Tangara à calotte grise **Spanish**: Hemispingo Coronigrís
German: Graukappenhemispingus
Other common names: Grey-capped Tanager

Taxonomy. *Chlorospingus reyi* Berlepsch, 1885, Mérida, Venezuela.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. Monotypic.
Distribution. Andes of Trujillo, Mérida and N Táchira, in W Venezuela.



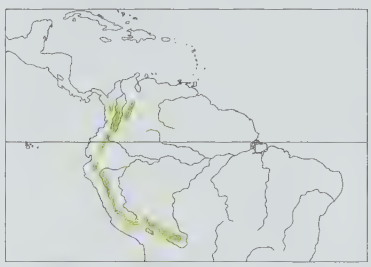
Descriptive notes. 14 cm. Rather plain hemispingus with small, relatively thin bill. Has crown down to bottom of eye and to nape grey (hooded appearance), upperparts, including tail and and upperwing-coverts, bright yellowish-olive (contrasting somewhat with cap); flight-feathers dusky, edged yellowish-olive; side of head olive-yellow, becoming plain yellow on throat and underparts, with tinge of olive on sides and flanks; iris dark brown; bill dark grey; legs greyish-horn. Sexes similar. Immature is similar to adult, but duller. Voice. Possible song a sharp insistent "tee chew chew", often followed by several single "chew" notes, or "stit-sit, seet!". Calls include buzzy "bzit" notes during foraging; also a high, thin "seep", longer "seeeep", and thin chittering notes.
Habitat. Humid and wet, mossy montane forest and forest borders with *Chusquea* bamboo; almost always in or near bamboo. Recorded at 1900–3200 m; most numerous at 2150–3000 m.
Food and Feeding. Little information on diet; appears to be mainly small arthropods. Occurs in pairs and in groups of up to 20 individuals (sometimes more) which forage with mixed flocks, in which often the dominant or nuclear species. Active but methodical; hops along branches and bamboo stems, examines leaf surfaces, especially of bamboo, by peering, reaching and occasionally hanging downward as it works over foliage; takes prey most often from upper surface of foliage. Stays mainly in lower levels (2–8 m up) of forest; usually fairly easy to see, often coming to forest edge along roadsides. General behaviour seems much like that of *H. atropileus*.
Breeding. No information.
Movements. Resident. No local or seasonal movements reported.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Cordillera de Mérida EBA. Fairly common locally. Has small range. The most important protected area within this species' range is La Sierra Nevada National Park (in Mérida), which includes a large intact tract of montane forest. Although it has a small global range and is doubtless vulnerable, a sizeable portion of its total range is well protected at present. Highland areas outside the park are subject to intensive pressure from human colonization and cultivation, which could increase the risk to this species.
Bibliography. Anon. (2010a), Athanas (2006), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), Hilty (2003), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1950, 1963), Ridgely & Tudor (1989, 2009), Stattersfield & Capper (2000).

22. Oleaginous Hemispingus

Hemispingus frontalis

French: Tangara ocré **German**: Olivrückenhemispingus **Spanish**: Hemispingo Oleaginoso
Other common names: Oleaginous Tanager; Ochraceous/Merida Hemispingus (*ignobilis*)

Taxonomy. *H.*[*ylophilus*] *frontalis* Tschudi, 1844, east slope of Andes, Peru.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. Has been suggested that race *ignobilis* might merit elevation to species rank, although vocal and behavioural data as yet incomplete. In addition, all four Venezuelan races differ considerably from nominate, but variation appears to be clinal, those farthest E (in NE Venezuela, hence farthest from Andes) differing the most. Review of geographical variation warranted. Five subspecies currently recognized.
Subspecies and Distribution.
H. f. flavidorsalis Phelps, Sr & Phelps, Jr, 1953 – Perijá Mts, in NW Venezuela (probably also on Colombian side).
H. f. hanieli Hellmayr & Seilern, 1914 – coastal range in N Venezuela (Aragua, Vargas, Distrito Federal and Miranda).
H. f. iteratus Chapman, 1925 – mountains of NE Venezuela (Sucre and Monagas).
H. f. ignobilis (P. L. Sclater, 1862) – Andes of W Venezuela from Lara S to N Táchira.
H. f. frontalis (Tschudi, 1844) – Colombia (W Andes of Antioquia, including E slope near Jardín, S very locally to Cauca; C & E Andes, including entire E slope of E range, patchily S of Cundinamarca), and Ecuador (E slope and locally in NW) and Peru S to C Cuzco.



Descriptive notes. 14 cm; 14–20 g. Dingy, dull hemispingus with relatively slender bill. Nominate race has long, narrow, weakly indicated yellowish supercilium (most obvious in front of eye); crown and entire upperparts, including upperwing-coverts and tail, dull dirty olive, flight-feathers narrowly edged cinnamon; dingy olive-yellow below, more olive on sides, tinged cinnamon on undertail-coverts; iris dark brown; bill dusky grey; legs pale brownish to brownish-grey. Sexes similar. Juvenile lacks supercilium, is even duller and dingier than adult; immature like adult but duller. N races differ from nominate in generally brighter coloration: *hanieli* has brighter and more pronounced yellow supercilium, and is more yellow-ochre below; *iteratus* differs from previous in having supercilium and throat tinged rich buff to orange-buff; *ignobilis* has greenish-yellow supercilium, with pale buffy throat better demarcated from breast than in other races; *flavidorsalis* has more olive upperparts, flight-feathers edged olive-green, and supercilium and throat with buff-yellow tinge. Voice. Song, by pair, trio or quartet (occasionally quintet) of foraging birds in early morning, more or less simultaneously by group-members at intervals of c. 15 seconds: one individual (same one each time?) starts, others immediately join in with identical songs sounding slightly out of sync, producing vibrating chorus lasting c. 5 seconds, each bird singing chattery stream of high-pitched "chipa'chipa' chip-chit'chit'chit'chit'it'it'it...", accelerating, then slowing. Rather quiet during day. Soft "chit" notes during foraging.
Habitat. Mostly interior of humid montane forest, especially in thicker vegetation, vine tangles and dense shrubbery; less frequently at forest borders. At 1400–2900 m in Venezuela; 1500–2700 m in Colombia; mostly 1500–2600 m in Ecuador and Peru.
Food and Feeding. Arthropods. Forages in pairs, in family parties and in compact groups of c. 4–8 individuals, accompanying (sometimes as dominant species) understorey mixed flocks. Industrious dead-leaf specialist; groups work through undergrowth or slightly higher, especially in vines and cluttered areas, flying a few metres at a time, hopping up branches in rather jerky manner while constantly flicking tail and peering at foliage, or, more often, fly or hop directly to clumps of curled, hanging dead leaves and inspect these by clinging, hanging upside-down or stretching down to peer into clump. Forages also on live green leaves, sometimes alternating between dead and live surfaces.
Breeding. Seven breeding-condition birds Jun–Nov in NW Venezuela (Perijá Mts) and N part of E Andes in Colombia; juvenile in Apr in C Peru (Junín). Eggs reportedly white. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common throughout range. Found in numerous protected sites in much of range, although increasing human settlement and deforestation may place this species at risk elsewhere.
Bibliography. Clements & Shany (2001), Donegan & Dávalos (1999), Fjeldså & Krabbe (1990), Hilty (1999, 2003), Hilty & Brown (1986), Lovette & Bermingham (2002), Mee *et al.* (2002), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Nehrkorn (1899), Parker *et al.* (1985), Phelps & Phelps (1950, 1963), Remsen *et al.* (2010), Restall *et al.* (2006), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schäfer & Phelps (1954), Schulenberg (2000b), Schulenberg *et al.* (2007), Walker (2001), Yuri & Mindell (2002), Zimmer (1947b).

23. Black-eared Hemispingus

Hemispingus melanotis

French: Tangara barbouillé **Spanish**: Hemispingo Orejinegro
German: Schwarzwangenhemispingus
Other common names: Black-eared Tanager

Taxonomy. *Chlorospingus melanotis* P. L. Sclater, 1855, "Bogotá".
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. This species, *H. piurae* and *H. ochraceus* usually treated as conspecific, but differ from one another markedly in plumage and habitat and all tentatively given full species rank; review warranted. Three subspecies recognized.
Subspecies and Distribution.
H. m. melanotis (P. L. Sclater, 1855) – Andes of W Venezuela (S Táchira) S on W slope of E Andes of Colombia (Santander and SE Boyacá S to head of Magdalena Valley, in Huila), also W Andes (E slope near Jardín, in Antioquia) and C Andes (Antioquia S to E slope in Nariño) of Colombia (probably also E slope of E Andes); also, E slope in Ecuador S to Tungurahua (Baños and Ambato) and in SE (Podocarpus National Park).
H. m. berlepschi (Taczanowski, 1880) – E slope of Andes in Peru from Amazonas S to N Cuzco.
H. m. castaneicollis (P. L. Sclater, 1858) – E slope in SE Peru (from Puno) S to C Bolivia (W Santa Cruz).

Descriptive notes. 13–14 cm; 13–22 g. Bill relatively small and slender. Nominate race has crown and nape grey, side of head blackish, narrow greyish-white supraloral line (often obscure or lacking), inconspicuous white arc below eye; upperparts, including tail and upperwing-coverts, olive-grey, tinged brownish; primary coverts black, flight-feathers dusky, edged and tinged olive-grey; throat and underparts cinnamon to pale orangish-cinnamon, becoming whitish on centre of belly; sides and flanks tinged brownish, undertail-coverts buffy cinnamon; iris dark brown; bill blackish; legs brownish. Sexes similar. Juvenile is very dull and nondescript; immature like adult but much duller. Race *berlepschi* resembles nominate, but has black chin and richer, more rufous throat and chest; *castaneicollis* has fairly long, narrow and weak white supercilium (sometimes lacking or nearly so), more black on side of head and black upper throat. Voice. In SE Peru (Cuzco, 1500 m) at dawn, individuals (race *berlepschi*) sing duets, trios or quartets of high, fast, tinkling "tsink'a'lee, tsink'a'lee, tsink'a'lee... ti, ti..ti", typically 5–6 "tsink'a'lee" phrases in almost explosive burst, then dying away and ending with irregular "ti" notes for few seconds, before song abruptly restarted by pair or group, song bout often continuing for several minutes. Song described also as fast sputtering chatter (2–3 seconds) of "jit" or "ja-jit" notes accelerating into twitter or sometimes slowing to rhythmic "ji-ja-jit ji-ja-jit ji-ja-jit", with intervals of 3–12 seconds between songs; also as rhythmic, accentuated "dididadidadid...", 2–3 seconds. In Bolivia (*castaneicollis*) fairly high, squeaky or wheezy "jit" or "ja-jit"; in alarm, same calls in series while flicking wings.
Habitat. Mainly in undergrowth of humid montane forest, especially in *Chusquea* bamboo or along thick shrubby or vine-covered forest borders. Recorded at 1800–2800 m in Venezuela; 1700–2900 m in Colombia; mostly 1800–2700 m in Ecuador; 1100–2200 m on E slope in Peru.
Food and Feeding. Of 13 stomachs examined, eleven held only animal matter and two both animal and vegetable matter; contents included beetles (Coleoptera) and other insect parts, also seeds. Pairs or groups of 3–4 individuals regularly follow mixed-species flocks and forage from understorey to middle levels (mostly 1–6 m up), occasionally into subcanopy, but more often low, especially along forest borders. Hops actively and alertly through foliage, gleans or picks insects from leaves, and often checks whorls of dead bamboo leaves; may occasionally hang from leaves.
Breeding. One bird in breeding condition in Sept in Colombia (Cundinamarca) and fledglings seen in Nov in Bolivia (Cochabamba). No other information.
Movements. Resident.
Status and Conservation. Not assessed. Probably not globally threatened. Uncommon to locally fairly common over most of range. Found in numerous middle-elevation protected areas scattered

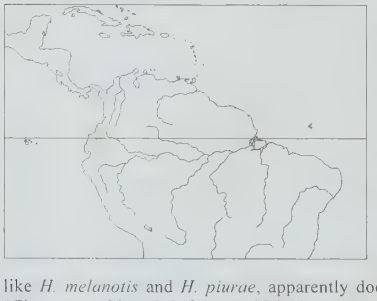
throughout range. Outside these areas may be assumed to be in decline owing to ongoing human colonization, forest destruction and consequent fragmentation of habitat.
Bibliography. Anon. (2000), Clements & Shany (2001), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1963), Remsen, Cadena *et al.* (2010), Remsen, Traylor & Parkes (1987), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg (2000b), Schulenberg *et al.* (2007), Walker (2001), Weske (1972), Zimmer (1947b).

24. Piura Hemispingus

Hemispingus piurae

French: Tangara de Piura **German**: Schwarzscheitelhemispingus **Spanish**: Hemispingo de Piura
Other common names: Piura Tanager

Taxonomy. *Hemispingus piurae* Chapman, 1923, Palambla, 4000 feet [c. 1220 m], Piura, northwest Peru.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. This species, *H. melanotis* and *H. ochraceus* usually treated as conspecific, but differ from one another markedly in plumage and habitat and all tentatively accorded full species rank; also, present species exhibits some vocal differences, and limited molecular-genetic data suggest that it is at least as distinct from *H. melanotis* as latter is from *H. frontalis*; review of group warranted. Two subspecies recognized.
Subspecies and Distribution.
H. p. piurae Chapman, 1923 – extreme S Ecuador (S Loja) and immediately adjacent Peru (N end of both slopes of W Andes in Piura and Cajamarca).
H. p. macrophrys Koepcke, 1961 – La Libertad (upper R Chicama valley, on W slope of Andes), in NW Peru.



Descriptive notes. 14·5 cm. Small slender bill. Nominate race has head and throat black, sharply contrasting long, narrow white supercilium from bill to nape, small white arc below eye; upperparts uniformly brownish-grey, primary coverts dusky, flight-feathers dusky, edged and tinged brownish-grey; entire underparts rich cinnamon-rufous; iris dark brown; bill black; legs light brown. Sexes similar. Juvenile undescribed. Race *macrophrys* is slightly darker than nominate. Voice. Not well known. Song similar to that of *H. melanotis*, but delivery rate somewhat slower.
Habitat. Humid montane forest, primarily where dense understorey of *Chusquea* bamboo present; also second-growth woodland. Reported at c. 2000–2500 m in S Ecuador; generally 1200–3050 m in NW Peru, e.g. 2450–2950 m in Huancabamba region of E Piura.
Food and Feeding. Arthropods, presumably also some vegetable matter. Usually in pairs, most often independently of mixed-species flocks, although in Peru considered regular member of latter. Forages from understorey to middle levels or higher, generally low down and in cover. Hops through foliage, gleans or picks items from leaves, checks whorls of dead bamboo leaves.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not assessed. Rare and local in S Ecuador; somewhat more numerous in NW Peru. In Ecuador, known only from S Loja, in extreme S: a specimen and sight records at Utuana, and several records at El Tundo Natural Reserve, near Sozoranga. In Ecuador, much of this species' habitat has been degraded or destroyed through cutting and burning; although it seems capable of surviving in secondary habitats, its global range is very small. If treatment as a full species found to be justified, listing as Near-threatened would seem appropriate.
Bibliography. Best *et al.* (1993), Collar *et al.* (1992), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (2003), García-Moreno *et al.* (2001), Parker *et al.* (1985), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007).

25. Western Hemispingus

Hemispingus ochraceus

French: Tangara de Berlepsch **German**: Ockerbrusthemispingus **Spanish**: Hemispingo Ocráceo
Other common names: Western Tanager(!)

Taxonomy. *Chlorospingus ochraceus* Berlepsch and Taczanowski, 1884, Cayandeled, western Ecuador.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. This species, *H. melanotis* and *H. piurae* usually treated as conspecific, but differ from one another markedly in plumage and habitat and all tentatively given full species rank; review of group warranted. Monotypic.
Distribution. W slope of Andes in SW Colombia (Nariño) and Ecuador (S to Chimborazo).

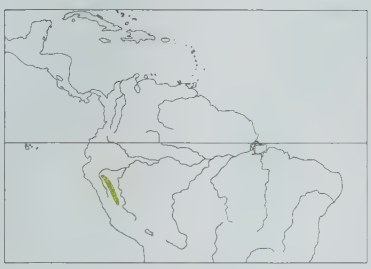
Descriptive notes. 14·5 cm. Much duller and more uniform than *H. melanotis* and *H. piurae*, and easily overlooked as an immature bird. Has crown to upperparts, including tail and entire wing, dull faded grey, back tinged olive; lores, area around eye and cheek dusky (not black) to dusky brown, contrasting little with rest of plumage; drab buffy olivaceous below, slightly brighter buff on undertail-coverts; iris dark brown; bill black; legs light brown. Sexes similar. Juvenile undescribed. Voice. Little definite information. Song reported as similar to that of *H. melanotis*.
Habitat. Moist to humid woodland and forest and older second growth in W Ecuador. Unlike *H. melanotis* and *H. piurae*, apparently does not exhibit particular affinity for bamboo (*Chusquea*), although it favours thick shrubby undergrowth. Recorded at 1600–2200 m.
Food and Feeding. Poorly known. No information on diet. Pairs or small groups are inconspicuous associates of mixed-species flocks, foraging in lower growth.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not assessed. Little information on status, and only a small number of specimens and sightings; possibly rare and/or local. Since before end of 20th century, this species has been reported by various observers along the Nono–Mindo road and Chiriboga road, in NW Ecuador (Pichincha). Its occurrence in protected areas, if any, is uncertain.
Bibliography. Fjeldså & Krabbe (1990), García-Moreno *et al.* (2001), Moore *et al.* (1999), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007).

26. Slaty-backed Hemispingus

Hemispingus goeringi

French: Tangara de Goering **German**: Graurückenhemispingus **Spanish**: Hemispingo Dorsigrís
Other common names: Slaty-backed Tanager

Taxonomy. *Chlorospingus goeringi* P. L. Sclater and Salvin, 1871, Páramos de Mérida, Venezuela.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. Monotypic.
Distribution. Andes of Mérida and N Táchira, in W Venezuela.



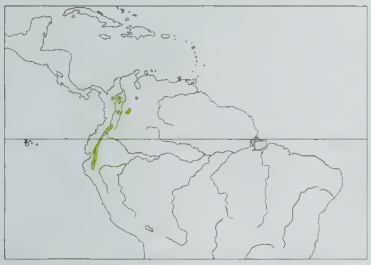
Descriptive notes. 14 cm. Legs unusually long and heavy; small slender bill. Has crown, nape and side of head deep black, long broad white supercilium from near bill to nape; mantle slaty, this becoming dark grey on rest of upperparts, including upperwing; rich tawny-rufous below, flanks tinged olive-brown; iris dark brown; upper mandible black, lower mandible grey; legs dark horn-grey. Differs from very similar *H. piurae* mainly in decidedly richer and brighter colours and much heavier legs. Sexes similar. Juvenile undescribed. Voice. Song, given a few times at dawn, and often as duet by mated pair, an energetic series of rapid staccato notes with "plink" notes throughout, may continue uninterrupted for a minute or more. Dawn song a continuous stream of moderately high-pitched, harsh notes by one bird, "ch-d-d-d-d-d-d-d...", and more pleasant high, musical, almost tinkling series by mate, "chi-ti-tee chi-ti-tee...", the two song types given simultaneously, presumably as duet, for up to 3 minutes.
Habitat. Wet upper montane forest, especially in dense shrubby borders, and stunted elfin forest, where often in or near bamboo (possibly a requirement). Recorded also in dense second-growth shrubbery bordering fields. At 2360–3200 m; sight records down to 2300 m in N Táchira.
Food and Feeding. Arthropods; possibly some vegetable items. Most often in pairs, also singly, and occasionally in groups (possibly families) of up to five individuals; at dawn forages alone or in pairs, during day most often with mixed flocks containing New World warblers, and species of *Diglossa*, *Conirostrum* and other tanagers. Forages from ground to c. 5 m up, mostly within dense cover, appearing momentarily, then disappearing or fluttering across open space and quickly diving into cover; at dawn also hops on ground or in grass at forest edge. Reaches out or up for prey; often makes "springy" upward leaps to pick prey from beneath leaves, or to peck overhead prey.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Cordillera de Mérida EBA. Uncommon and easily overlooked. Small range, estimated at c. 1700 km², now much fragmented by deforestation. Recorded in S half of Mérida (Páramo La Negra, Páramo Escorial, Páramo Aricagua, and Mucuchíes; sight record above La Mucuy) and S into N Táchira (Páramo Zumbador; sight record at Páramo Batallón) N of Táchira Depression. May persist in shrubby secondary and degraded habitats along forest borders, but, because of ongoing deforestation within its range, must be regarded as declining. Seen with some frequency at upper elevations above La Mucuy, in Sierra Nevada National Park (Mérida), the largest protected area within its range, and frequent in Jan–Mar 1993 to 1999 at 2300–2500 m near Páramo Batallón (Mérida–Táchira border).
Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldså & Krabbe (1990), Hilty (2003), Isler & Isler (1999), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1963), Stattersfield & Capper (2000).

27. Rufous-browed Hemispingus

Hemispingus rufosuperciliaris

French: Tangara à sourcils fauves **Spanish**: Hemispingo Cejirrufo
German: Zimtbrauenhemispingus
Other common names: Rufous-browed Tanager

Taxonomy. *Hemispingus rufosuperciliaris* Blake and Hocking, 1974, Bosque Huaylaspampa, c. 8400 feet [c. 2560 m], Huánuco, Peru.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. Monotypic.
Distribution. E slope of Andes in Peru from Amazonas (S of R Marañón in Cordillera de Colán) S to Huánuco (W of R Huallaga in Acomayo–Carpish Ridge region of Carpish Mts).
Descriptive notes. 15 cm; 26–33 g. Distinctive hemispingus with bold rufous eyebrow and underparts; bill relatively small and thin, legs and feet strong, tarsus rather long. Has crown, nape, lores, ear-coverts and side of neck black, long and unusually broad bright cinnamon-rufous supercilium arcing over eye and extending back to nape; upperparts, including entire upperwing and tail, blackish-slate; throat, breast, sides and most of abdomen uniformly cinnamon-rufous, becoming dark grey with slight tinge of brown on lower abdomen, undertail-coverts, flanks and thighs, some white on central belly; underwing dull black, underwing-coverts slightly paler, more greyish; iris brown to dark reddish-brown; bill dusky above, blue-grey below, dusky tip; legs brown to greyish-brown, dark brown or black. Sexes similar. Juvenile and immature undescribed. Voice. Song a mixture of short, nasal and squeaky notes with distinctive long and slurred squeals inserted irregularly in jerky cadence, "nya-tit-tit—tit-squeal! tit-tit-squeal! nya-nya tit-squeal!..." and so on for up to several minutes, with only occasional short pauses. May sing duets. Call a scratchy "chenk", sometimes in rapid succession by members of group.



Habitat. Undergrowth of wet, mossy montane and elfin forest, especially in extensive thickets of *Chusquea* bamboo and in dense moss-laden shrubbery along borders of forest; occasionally in adjacent hedgerows and other second growth. Recorded at 2550–3500 m, mostly above 2800 m.
Food and Feeding. Arthropods and berries. Four stomachs contained only animal matter, two vegetable matter, and one both; contents included beetles (Coleoptera), caterpillars, seeds, and tiny stones. Mainly in pairs, occasionally groups of three or four individuals, alone or in mixed flocks, especially those with Citrine Warblers (*Basileuterus luteoviridis*) and/or Peruvian Wrens (*Cinnycerthia peruana*). Inconspicuous, mostly in dense understorey; moves sluggishly, more like a brush-finch (*Atlapetes*) than a hemispingus. Forages within c. 1 m of ground, less often to 2 m, hopping deliberately on large mossy limbs and bamboo canes; regularly on/very near ground, especially in *Chusquea* thickets and in tall grass at base of tree-line bushes (long strong legs suggest that much time spent on ground). Seen to reach down or outwards to pick prey from moss.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in North-east Peruvian Cordilleras EBA. Rare and very local. Estimated global population fewer than 10,000 individuals; believed declining. At type locality in 1973, when first discovered, considered fairly common and seen on most days. Elsewhere, recorded at only very few sites, and these increasingly fragmented because of widespread deforestation and wood-cutting activities for firewood.
Bibliography. Anon. (2010a), Blake & Hocking (1974), Butchart & Stattersfield (2004), Fjeldså & Krabbe (1990), Isler & Isler (1999), Schulenberg *et al.* (2007), Stattersfield & Capper (2000), Tallman (1974).

28. **Black-headed Hemispingus**

Hemispingus verticalis

French: Tangara à tête noire **German**: Schwarzkopfhemispingus **Spanish**: Hemispingo Cabecinegro
Other common names: Black-headed Tanager(!)

Taxonomy. *Nemosia verticalis* Lafresnaye, 1840, Santa Fé de Bogotá, Colombia.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. Forms a superspecies with *H. xanthophthalmus*, both formerly placed in separate genus, *Pseudospingus*. Monotypic.
Distribution. Andes in W Venezuela (S Táchira), Colombia (W range in Antioquia, C range S to Nariño, and E range in Cundinamarca), Ecuador (E slope in Carchi, Napo and Zamora-Chinchipe) and N Peru (Piura, near Piura–Cajamarca border).

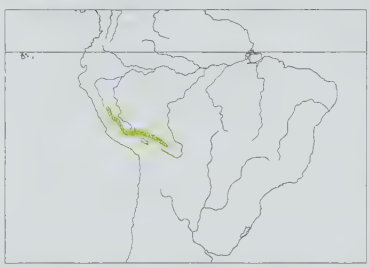
Descriptive notes. 14 cm; 12–15·7 g. A small, rather dark hemispingus with thin bill. Has long clay-coloured median crownstripe, head and throat otherwise black (black rounded off at rear, looking like large black discs on sides of head); upperparts, including tail, dark grey; upperwing-coverts dark grey, faintly edged brown, flight-feathers dusky, outer feathers edged brown, inner remiges edged dark grey; underparts pale grey, becoming whitish on belly and tinged buff on undertail-coverts; iris white; bill and legs blackish. Sexes similar. Immature is rather like adult (including pale eyes), but with irregular whitish mark over eye, whitish throat mixed with black, central underparts whitish, and grey below confined mainly to sides and flanks. VOICE. Song, singly or in duets or trios, a burst 5–15 seconds long of squeaky twittering notes mixed with stream of higher-pitched thin "seet" or "steet" notes; squeaky notes may cease for intervals of 10–12 seconds before another song initiated, but very high "seet" notes may continue at slower rate. Also described (in Peru) as a rapid series of "tchip" notes accelerating into a jumble of squeaky warbles. Calls high "tweet" and "tiip" when foraging.
Habitat. Dense wet montane forest and mossy elfin woodland at tree-line, ranging out into tree-line shrubs and wooded borders; often around small openings in vegetation, occasionally in isolated patches of elfin woodland away from forest. At 2800–3000 m in Venezuela; 3000–3600 m in Colombia; mostly 2700–3400 m in Ecuador; 2700–3600 m in Peru.
Food and Feeding. Insects; also various small berries, including those of melastomes. Contents of two stomachs were insects, including caterpillars and beetles (Coleoptera). In pairs and in groups of 3–5 (rarely 12) individuals, habitually with mixed flocks. Restless, active, fast-moving. Forages primarily in crown layers of shrubs, trees and occasionally bamboo, where it hops out towards tips of branches and stands/walks on tops of leaves and leaf clusters. Perches horizontally, often atop stiff leaves, and gleans items from upper leaf surfaces, petioles and leaf axils.
Breeding. Breeding-condition bird and two immatures in Sept in Colombia. No other information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Found in numerous parks and protected sites, but intensive pressure from human colonization could place this species at risk in the future.
Bibliography. Anon. (2000), Clements & Shany (2001), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (2003), García-Moreno *et al.* (2001), Hellmayr (1936), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Krabbe *et al.* (2001), Meyer de Schauensee (1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Parker *et al.* (1985), Phelps & Phelps (1950), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Vuilleumier & Ewert (1978).

29. **Drab Hemispingus**

Hemispingus xanthophthalmus

French: Tangara aux yeux jaunes **German**: Schlichthemispingis **Spanish**: Hemispingo Modesto
Other common names: Dark Hemispingus, Drab Tanager

Taxonomy. *Dacnis xanthophthalma* Taczanowski, 1874, Maraynioc, Junín, Peru.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. Forms a superspecies with *H. verticalis*, both formerly placed in separate genus, *Pseudospingus*. Monotypic.
Distribution. E slope of Andes in Peru (S side of Marañón Valley in Amazonas) S to W Bolivia (La Paz).



Descriptive notes. 13 cm; 10–15 g. A small, slender, relatively thin-billed, rather dull hemispingus. Has crown to nape, side of head to below eye, and upperparts, including tail and upperwing, plain brownish-grey; dull greyish-white below, whitest on throat and belly, greyish tinge on flanks and buff tinge on undertail-coverts; iris white to pale yellow; bill and legs blackish. Sexes similar. Juvenile undescribed. VOICE. Song, often as duet by pair, a fast sputtering series of variably pitched notes without obvious pattern, up to 8 seconds long, sometimes repeated at short intervals for up to several minutes; most songs short or staccato and squeaky, some longer and with chirping or squealing quality; some may recall those of *H. melanotis*, *Cnemoscopus rubrirostris*, or various New World warblers or *Diglossa* flowerpiercers. Call a high "it-sit" and "tseee".
Habitat. Humid montane forest, elfin forest and forest borders, to tree-line; locally in patches of degraded and scrubby secondary woodland. At 2200–3350 m in Peru and 2900–3050 m in Bolivia.
Food and Feeding. Nine stomachs contained insects. In pairs and in small groups of up to 5–6 individuals, usually with mixed flocks. Forages from eye level to 18 m up, mostly c. 3–12 m up in crown and upper foliage of bushes and small trees. Stands, walks and hops on tops of stiff, dense canopy leaves of *Escallonia*, *Weinmannia*, *Clusia* and other dense, flat-topped trees, where it gleans small prey from upper leaf surfaces; also hops out along small branches to glean or pick prey from leaf tops, twigs and flower stalks. Occasionally pursues prey in short flutter-chases.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Occurs in a few protected areas, most notably Manu National Park, in Peru. Much suitable montane and tree-line habitat exists also in unprotected areas within this species' range, although locally these areas are becoming increasingly degraded or fragmented owing to deforestation and wood-cutting. This species seems able to forage also in various early and scrubby stages of regrowth vegetation.
Bibliography. 30. **Three-striped Hemispingus**

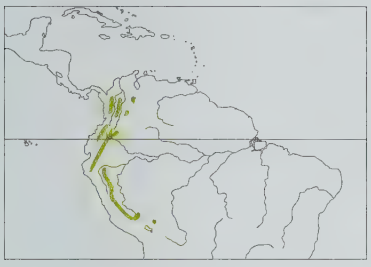
Hemispingus trifasciatus

French: Tangara trifascié **German**: Streifenhemispingus **Spanish**: Hemispingo Trilistado
Other common names: Three-striped Tanager

Taxonomy. *Microspingus trifasciatus* Taczanowski, 1874, Maraynioc, Junín, Peru.
Genus has been thought to belong with New World warblers (Parulidae), but recent molecular-genetic data support placement in present family; monophyly of genus questioned, supported by some molecular data, but other molecular data equivocal. This species has been placed in a monotypic genus, *Microspingus*, but recent molecular-genetic data support inclusion in present genus, although relationships with other taxa within this uncertain. Monotypic.
Distribution. E slope of Andes in C Peru (S from Huánuco, W of R Huallaga) S to C Bolivia (Cochabamba).

Descriptive notes. 13 cm; 12–16 g. A small hemispingus with small slender bill, pale wingbars. Has head black, long broad buffy-white supercilium; median crownstripe and upperparts, including tail, brownish-olive; upperwing-coverts pale brownish-olive, median and greater coverts narrowly edged and more broadly tipped buff (forming two prominent wingbars), flight-feathers dusky olive, margined yellowish-buff; chin light buff, throat and underparts ochre-buff, richest on breast, paler and more yellowish on belly; in general, plumage palest in N of range, slightly darker and ochraceous in S; iris dark brown; bill black; legs brownish. Sexes similar. Juvenile undescribed. VOICE. Dawn song, from exposed dead branch above canopy, a series of buzzy "tzit" notes, c. 40 per minute; another song (possibly day song) a buzzy, chattering phrase. Call a high, spitting "swit", sometimes in rapid series or given in chorus, as before crossing an opening.
Habitat. Canopy of humid elfin forest at tree-line, also stunted forest islands at edge of *páramo*, more rarely in thickets of *Chusquea* bamboo. Recorded at c. 3000–3650 m in Peru; 2800–4250 m, occasionally as low as 2375 m, in Bolivia.
Food and Feeding. Insects; contents of ten stomachs insects, including caterpillars. Pairs or groups of 4–6 individuals, rarely up to ten, follow mixed flocks or behave as nuclear species in flocks; infrequently, forage independently. In Bolivia median foraging height was c. 5·5 m, and more than two-thirds of 58 observations within 2 m of tops of vegetation. Gleans from top and undersurface of leaves about equally; 87% of prey taken by simple gleaning movements, remainder by reaching, hanging or sallying. In Peru, gleaned from leaves at or near ends of limbs, also from twigs, picked at moss and lichens, and hung upside-down to pick at stems and small leaves.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. This species' global range is rather small, and limited to narrow band of tree-line vegetation that is subject to pressure from human colonization, deforestation and firewood-cutting; this could place some populations at risk.
Bibliography. Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (2003), García-Moreno *et al.* (2001), Hellmayr (1936), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Parker & O'Neill (1980), Remsen (1984, 1985), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Walker (2001), Zimmer (1947b).

Genus *CNEMOSCOPUS*



Bangs & T. E. Penard, 1919

31. **Grey-hooded Bush-tanager**

Cnemoscopus rubrirostris

French: Tangara capucin **German**: Graukopf-Buschtangare **Spanish**: Tangara Capuchigrís
Other common names: Grey-hooded Tanager; Red-bellied Bush-tanager (*rubrirostris*); Golden-bellied Bush-tanager (*chrysogaster*)

Taxonomy. *Arremon rubrirostris* Lafresnaye, 1840, Santa Fé de Bogotá, Colombia.
Genus sometimes considered to belong with New World warbler family (Parulidae), but recent molecular-genetic data support placement in present family. This species has in the past been placed variously in *Chlorospingus* and in *Hemispingus*; appears closer to latter in morphology, feeding behaviour and vocalizations, and close relationship supported by molecular-genetic data. S race *chrysogaster*, which differs from nominate in plumage and size, but is similar to it in behaviour, has been considered a separate species. Two subspecies currently recognized.
Subspecies and Distribution.
C. r. rubrirostris (Lafresnaye, 1840) – S end of Andes in W Venezuela (S Táchira) and generally in Andes of Colombia and NW & E Ecuador.
C. r. chrysogaster (Taczanowski, 1875) – Andes of NW & E Peru (Piura; Amazonas S to Junín); W Bolivia (near Tokoaque, in La Paz).
Descriptive notes. 17 cm, 18·5–23 g (*rubrirostris*); 15 cm, 13–22·5 g (*chrysogaster*). Nominate race has entire head, throat and chest medium grey ("hood"), throat and chest slightly paler; upperparts, including uppertail-coverts, tail and upperwing-coverts, yellowish-olive; primary coverts black, flight-feathers dusky, edged olive-green; underparts below chest clear yellow; iris dull red; bill and legs pinkish. Sexes similar. Juvenile undescribed. Race *chrysogaster* differs from nominate in smaller size, paler throat and chest, brighter yellow underparts, pale brown eyes, and dusky bill and legs. Voice. Song of nominate race a 2-second jumble of high, squeaky, sputtering notes that end in downward-inflected whistle, e.g. "twitity, twitity, sweeee", or with last note repeated several times; flows into "chip" notes between groups of phrases. Song of *chrysogaster* similar, but ending may be more varied. Call a high, sharp "seit".
Habitat. Humid and wet montane forest and forest borders; in some areas shows affinity for disturbed areas with alders (*Alnus*). Found at 1250–2150 m in Venezuela, 1900–3350 m in Colombia, 1900–3000 m in Ecuador and 2000–3100 m in Peru; mostly at c. 2100–3000 m.

Food and Feeding. Four stomachs of race *chrysogaster* contained animal matter, and one held vegetable matter; contents included caterpillars 2–4 cm long, also seeds. Overall more insectivorous than *Chlorospingus*. Occurs mostly in pairs or in small groups of up to about eight individuals that follow mixed-species flocks. Forages from eye level to canopy, but usually fairly high and most often at subcanopy levels. Forages out along larger branches with distinctive creeping or crouched gait and teetering movement of rear end, tail pumping downwards (constant tail-wagging behaviour distinctive). Peers at branch surfaces and especially at leaf undersurfaces, and may hang head downwards to inspect curled dead leaves; also sallies short distances to air within outer foliage.
Breeding. Three breeding-condition birds in Jul–Aug in Colombia (at N end of W & C Andes). Egg descriptions differ: one set reportedly pale greenish-white, thickly spotted reddish-lilac at large end; another bluish-white, sparsely marked with black spots. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common along most of E slope of Andes; elsewhere, records somewhat sparse. In NW Ecuador, known only from two sites in Pichincha; in Bolivia, sight records (Nov 2001) near Tokoaque, in La Paz. As with other forest-based Andean species living at middle and upper elevations, this tanager's habitat is subject to considerable pressure from human settlement, which could eventually place it at risk locally. Occurs within a considerable number of protected areas, ranging from Tamá National Park (Venezuela) and Las Orquídeas National Park (Colombia) S to Manu National Park (S Peru) and Madidi National Park (W Bolivia).
Bibliography. Berlepsch (1911), Burns (1997a), Burns *et al.* (2003), Donegan & Dávalos (1999), Fjeldså & Krabbe (1990), García-Moreno & Fjeldså (2003), Hennessey & Gomez (2003), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Krabbe *et al.* (2001), Nehrkorn (1899), Remsen *et al.* (2010), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sclater & Salvin (1879), Walker (2001), Weske (1972), Zimmer (1947b).

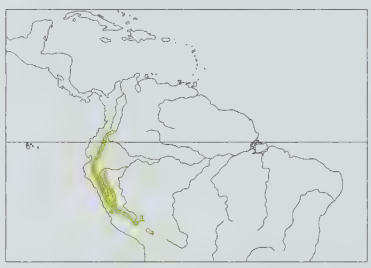
Genus *THLYPOPSIS* Cabanis, 1851

32. Fulvous-headed Tanager

Thlypopsis fulviceps

French: Tangara à tête fauve **German**: Rostkopftangare **Spanish**: Tangara Cabecifulva

Taxonomy. *Th.* [*lypopsis*] *fulviceps* Cabanis, 1851, Caracas, Venezuela.
Four subspecies recognized.
Subspecies and Distribution.
T. f. obscuriceps Phelps, Sr & Phelps, Jr, 1953 – Sierra de Perijá, on Colombia–Venezuela border.
T. f. fulviceps Cabanis, 1851 – mountains of N Venezuela (Carabobo E to Miranda; NE Anzoátegui, W Sucre and N Monagas).
T. f. meridensis Phelps, Sr & Phelps, Jr, 1962 – Andes of Mérida and N Táchira, in W Venezuela.
T. f. intensa Todd, 1917 – E slope of E Andes in N Colombia (Norte de Santander).
Possible sight record, race unknown (presumably *obscuriceps*), from upper R Frio region on W slope of Santa Marta Mts, in N Colombia; requires verification.



Descriptive notes. 12 cm; 11–13 g. A small grey tanager with conspicuous chestnut head and thin bill. Male nominate race has entire head, nape and throat rufous-chestnut (forming hood), throat slightly paler chestnut; upperparts, including upperwing-coverts, uppertail-coverts and tail grey; primary coverts dusky, flight-feathers dusky, edged grey; breast light grey, becoming whitish on centre of belly and undertail-coverts; iris dark brown; bill greyish above, often paler below at base; legs horn-grey. Female is similar to male, but throat paler, more rufous-buff. Juvenile undescribed. Race *obscuriceps* is very like nominate, but slightly darker grey above; *meridensis* also is very similar to nominate, but paler grey below, and undertail-coverts tinged grey; *intensa* differs in having head chestnut, darker than on other races, and undertail-coverts cinnamon. Voice. Song, infrequently heard during morning hours, a high "chi chi cht-cht-tit-t-t-t-t-t-t", accelerating and trailing off. Calls insignificant, high "tsit" and "chik" notes; rapid "chip" and "tsitt" notes when excited.
Habitat. Canopy vines and shrubby vine-tangled borders of moist to humid forest, second-growth woodland, and shrubby gardens in urban areas, e.g. Caracas (Venezuela). Most numerous in moist to semi-humid forest, e.g. S slope of coastal range below Rancho Grande Biological Station (Venezuela); numbers decrease sharply in more humid zones. At 1500–2300 m in Colombia and 750–2000 m in Venezuela.
Food and Feeding. Insects, including caterpillars; occasionally small berries, especially of Melastomataceae. One or two individuals, occasionally up to about five (possibly family parties), regularly associated with mixed-species flocks in canopy inside forest, and often much lower along forest borders. Notably active and alert, searching for food items mostly on leaves of various sizes, by perch-gleaning, reaching downwards from perch, clinging sideways or upside-down to leaves, pulling or tugging to extract prey, and often probing curled and hanging dead leaves. Occasionally sallies to undersurface of leaves.
Breeding. One bird in breeding condition in Apr in Perijá Mts, and three in Nov in Norte de Santander. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Caripe–Paria Region EBA, Cordillera de la Costa Central EBA, Cordillera de Mérida EBA and Colombian East Andes EBA. Uncommon to locally fairly common. Distribution somewhat spotty, perhaps owing to narrow habitat preferences. Population trends not documented, but likely to show a decline. Deforestation, fires and human colonization have resulted in loss of at least half of the species' habitat within its range, which has consequently contracted. Protected areas within its relatively small range in Venezuela include Henry Pittier National Park and Yacambú National Park.
Bibliography. Álvarez-Rebolledo *et al.* (2007), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1950, 1963), Salaman *et al.* (2008), Schäfer & Phelps (1954), Sharpe (2003), Strewe & Navarro (2004).

33. Rufous-chested Tanager

Thlypopsis ornata

French: Tangara à flancs roux **German**: Zimtbrusttangare **Spanish**: Tangara Pechicanela
Other common names: Fulvous-chested Tanager

Taxonomy. *Nemosia ornata* P. L. Sclater, 1859, Pallatanga, Ecuador.
May form a superspecies with *T. pectoralis*, and the two have been considered conspecific. Three subspecies recognized.
Subspecies and Distribution.
T. o. ornata (P. L. Sclater, 1859) – W slope of C Andes in Colombia (from Puracé, in Cauca) S locally in Ecuador (both slopes, and locally on slopes above C valley).
T. o. media J. T. Zimmer, 1930 – E slope of Andes in extreme S Ecuador (Morona-Santiago and Zamora-Chinchipe; also specimen from E Carachi) and Peru (S on W slope to Lima; locally E slope from Cajamarca S to Marañón Valley).
T. o. macropteryx Berlepsch & Stolzmann, 1896 – E slope of Andes in Peru (Junín; isolated records S to Cuzco).

Descriptive notes. 12–13 cm; 10–15 g. Small, thin-billed greyish tanager with rich rufous head and underparts. Male nominate race has entire head and throat to mid-breast, sides, flanks and undertail-coverts deep orange-rufous, richest on crown, slightly paler on throat; centre of lower breast and belly white; upperparts, including uppertail-coverts, tail and upperwing-coverts, uniformly brownish-grey, mantle contrasting sharply with orange-rufous of head; primary coverts dusky, flight-feathers dusky, edged dull grey; iris dark brown; bill dusky; legs dark grey. Female is similar to male, but paler, more olive, on crown and nape (little contrast with back), and paler below, especially on throat. Immature is overall paler and duller, looking much like a dull female. Race *media* differs from nominate mainly in slightly larger size; *macropteryx* also differs in slightly larger size, as well as darker crown, deeper and richer colour on throat and breast, and more extensively white belly. Voice. Song, infrequently heard (or not often recognized), is thin, high-pitched and apparently somewhat variable, in simplest form a sibilant "ti, ti, ti sib'bit-sib'bit-sib'bit-sib'bit se-bee", rising slightly at end, or ending may include complex jumble of notes, or may end in thin slightly rising trill. Some songs may be delivered as duet, second bird giving high chipping notes. Extent and frequency of song repertoire in this species (and congeners) not well understood. During foraging gives very high-pitched, thin "seek" notes.
Habitat. Shrubby montane-forest borders, especially scrubby or drier secondary montane woodland, patches of second growth away from forest, and wooded ravines; rarely, *Polylepis* woodland. In general scarce or absent in humid or wet regions. At 2000–3400 m in Colombia, but most records c. 2400–3000 m; in Ecuador mostly 1800–3000 m, but possibly once as low as 1200 m; in Peru 1600–3300 m, locally to 3800 m, on E Andean slope.
Food and Feeding. Insects; six stomachs contained animal matter, including beetles (Coleoptera), spiders (Araneae) and a caterpillar. Single birds, pairs, and families of 3–4 and more rarely up to 8 individuals forage alone or sometimes in association with mixed-species flocks. Restless and active as it moves through along branches and foliage, from below eye level up to canopy of low scrubby trees. Gleans insects from leaves, twigs, and arboreal dead leaves, also inspects flowers and occasionally hangs upside-down. Has been seen to probe *Diglossa* incisions in tubular flower corollas.
Breeding. In Ecuador, egg-laying noted on 1st Mar, fledglings mid-Mar, and nest-building at end Apr, suggesting breeding season from at least end Feb to end May, also active nests found in Mar–Apr in SW (Yungilla Valley, in Azuay) and juvenile in Mar in NW. Following details mainly from Azuay. Nest a small open cup, outside diameter c. 8·5 cm and depth 7·5 cm, made from coarse grass, narrow bamboo leaf blades, twigs and petioles, with fine pale grass and petioles tightly woven on inside of cup, placed c. 0·4–1·2 m above ground in grass or young second-growth bush in semi-open area. Clutch 2 eggs, white with red-brown blotches and streaks; no information on incubation and nestling periods.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon and rather local. Local in Colombia, and in Ecuador apparently more numerous in S. Tolerates highly degraded second growth and scrub, even along steep ravines, but near-complete deforestation and conversion to pastureland of much of this species' formerly wooded range poses a significant long-term risk. There are few protected areas within its range in Colombia.
Bibliography. Fjeldså & Krabbe (1990), Greeney *et al.* (2006), Hilty & Brown (1986), Isler & Isler (1999), Koepcke (1970), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Moynihan (1963b), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sibley & Monroe (1990), Vogt (2003), Walker (2001).

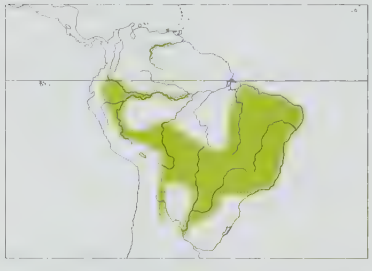
34. Brown-flanked Tanager

Thlypopsis pectoralis

French: Tangara à flancs bruns **German**: Braunflankentangare **Spanish**: Tangara Pectoral

On following pages: 35. Orange-headed Tanager (*Thlypopsis sordida*); 36. Buff-bellied Tanager (*Thlypopsis inornata*); 37. Rust-and-yellow Tanager (*Thlypopsis ruficeps*); 38. Chestnut-headed Tanager (*Pyrrhocoma ruficeps*); 39. White-rumped Tanager (*Cypsnagra hirundinacea*); 40. Pardusco (*Nephelornis oneilli*); 41. Black-goggled Tanager (*Trichothraupis melanops*).

Taxonomy. *Nemosia pectoralis* Taczanowski, 1884, Acancocha, Junín, Peru.
May form a superspecies with *T. ornata*, and the two have been considered conspecific. Monotypic.
Distribution. E slope of Andes in Huánuco, Pasco and Junín, in C Peru.



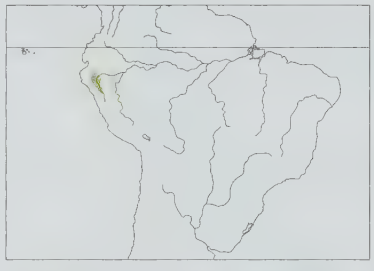
Descriptive notes. 12 cm; 14–17 g. A small, greyish tanager with rufous head and chest. Male has entire head to upper breast dark orange-rufous, contrasting with olive-grey to brownish-grey upperparts and tail; upperwing-coverts brownish-grey, primary coverts dusky, flight-feathers dusky, edged buffy grey; sides and flanks greyish-brown, contrasting with upper breast, centre of breast to belly white, undertail-coverts buff; iris dark brown; bill blackish; legs dark horn-grey. Distinguished from very similar *T. ornata* by brownish (not orange-rufous) sides and flanks. Female is like male, but throat paler. Immature is duller than adult, with olive-grey wash on crown. Voice. A soft high "tsit". A twittery "seet seet seet" is possibly a song, but song repertoire not known for certain.
Habitat. Dense shrubs on dry slopes, shrubbery along streams, alder (*Alnus*) thickets, hedgerows, occasionally humid forest borders or tall grass, weeds, brush and thickets adjacent to cultivated areas. Mainly dry to semi-arid zones in semi-open intermontane valleys. At 2500–3200 m.
Food and Feeding. Mostly tiny insects, also caterpillars and small adult moths (Lepidoptera). Usually in pairs, individuals staying close together, often no more than 1–2 m apart; has been seen in small mixed flocks with *T. ornata*. Forages mostly just inside outer foliage, working upwards from c. 1–3 m up in shrubs and small trees; during mid-day tends to remain within shrubs and less visible. Forages by hopping actively among interior branches and vines, inspecting curled dead leaves, sallying for disturbed or fleeing insects, peering or pecking at seed pods and flowers, and gleaning or reaching for insects on bare twig and branch surfaces and both surfaces of green leaves.
Breeding. Juveniles seen in Dec and Feb in Huánuco and Mar in Junín. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Peruvian High Andes EBA. Uncommon. Confined to a relatively small area, mainly on drier W side of E cordillera in C Peru, where it persists in highly degraded areas. Population trends undocumented, but the species is probably declining; could become vulnerable in the future from loss of dry scrub and woodland through persistent firewood-cutting. Few, if any, protected areas exist within this species' range.
Bibliography. Fjeldså & Krabbe (1990), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Moynihan (1979), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Zimmer (1930, 1947a).

35. Orange-headed Tanager

Thlypopsis sordida

French: Tangara à tête orange **German**: Orangekopftangare **Spanish**: Tangara Cabecinaranja

Taxonomy. *N.[emosia] sordida* d'Orbigny and Lafresnaye, 1837, Yuracares, Bolivia.
May form a superspecies with *T. inornata*. Three subspecies recognized.
Subspecies and Distribution.
T. s. orinocensis Friedmann, 1942 – R Orinoco (from near Soledad, in Bolívar, S to S of Puerto Ayacucho, in Amazonas), in C Venezuela.
T. s. chrysopis (P. L. Sclater & Salvin, 1880) – extreme S Colombia (E of Andes), E Ecuador, E Peru and W Brazil (E to R Madeira and R Jiparaná).
T. s. sordida (d'Orbigny & Lafresnaye, 1837) – S & E Brazil S of R Amazon (E & S Pará E to Ceará and Paraíba, S to Mato Grosso do Sul, São Paulo and Rio de Janeiro), E Bolivia, N Argentina (S to Tucumán, Corrientes and Misiones) and Paraguay.



Descriptive notes. 13 cm; 14–19 g. Small, rather drab, thin-billed tanager with yellow-orange head, and proportions like those of a New World warbler (Parulidae). Male nominate race has crown and side of head orange-rufous, turning bright yellow on lores, ocular area and throat; upperparts, including upper-tail-coverts, tail and upperwing-coverts, sandy-grey, primary coverts dusky, flight-feathers dusky, edged grey; underparts are buff to cinnamon, becoming whitish on centre of lower breast, belly and undertail-coverts; iris dark brown; bill dusky; legs horn-grey. Female is duller than male above, especially on crown, has lores, face and throat duller yellow, and yellow of head less extensive and contrasting less with back. Immature resembles female, but even dingier, greyish-olive above, including crown, and paler below. Race *orinocensis* has chest, upper breast, sides and flanks pale grey, tinged greyish-cinnamon; *chrysopis* is much like previous, but upperparts pure grey with little or no olive wash, and breast and sides light greyish-brown. Voice. Song (solo) varies geographically: in N Peru and Ecuador a high-pitched, jerky, rising-and-falling "pits'a, see-a, pits'a, see-ee", ending on high-pitched note; in NW Argentina (Calilegua National Park) a high-pitched, halting and jerky "seet, sit, a see-fits-za", also with rising-and-falling pattern. Duets (songs?) or excited chatter in N Peru and Bolivia a few high notes followed by fast, high chittering, given when perched or in flight, "seet seet t-t-t-t-t-t-t-t-t-t-d-dit". Year-round song in E Brazil (Rio de Janeiro) includes several song types, typical being a thin, high "tsap-tsip, tsip, tsip-tsop-tswit". Also in Brazil a high trill, "tsi . . . . tsrrrri". Calls include high "tseet" or "seet" or "sit", often doubled, tripled or repeated rapidly; rapid high chittering "sit-it-t-t-t-t-t-t", also "seet-a", given more slowly.
Habitat. In Venezuela and in W Amazonia found mainly in early successional vegetation on river islands and riverbanks, e.g. in tall *Gynerium* grass, willow (*Salix*), *Tessaria*, *Cecropia* and associated shrubbery, or in younger second growth near rivers. In areas S of Amazonia found in dry to semi-humid zones in canopy of open woodland, parks, shrubby gardens and *cerrado*, and in lighter riparian vegetation along watercourses. In NW Argentina occurs in scrub, brush and borders of dry open woodland, especially along intermittent riverbeds. Rarely or never found inside continuous forest or woodland. To c. 100 m in Venezuela and c. 400 m in Colombia; elsewhere to c. 800 m, and locally to 1500 m in Bolivia. The only member of the genus in Amazonian lowlands.
Food and Feeding. Of eight stomachs examined, three contained only vegetable matter, four only animal matter, and one contained both; contents included orthopterans, beetles (Coleoptera), flies (Diptera), spiders (Araneae), fruit pulp and seeds. Found in pairs and in family parties of 3–4 individuals, sometimes with mixed-species flocks but at least as often away from them. Forages in restless, active manner, much like parulid warblers; hops rapidly and gleans insects, mostly from foliage from about eye level or higher, to tops of small trees. More rarely flutters, or hovers, or sallies short distances to air for fleeing prey.
Breeding. One nest found, in Dec in Argentina: an open cup c. 2 m up; contained 2 eggs, bluish-white, marked with brown and cinnamon. Regularly parasitized by Shiny Cowbird (*Molothrus bonariensis*). No other information.
Movements. Seasonal movements reported in Brazil (Mato Grosso) and in N Argentina, where moves from Andean slopes to lowlands during austral winter months.
Status and Conservation. Not globally threatened. Uncommon to locally common. Occurs in a wide variety of mostly edge and secondary habitats. In a few areas it is under pressure from human colonization and clearing of land, but it is found within protected areas in almost all parts of its range, and occurs in such different ecosystems as those of Manu National Park, in Peru, and Calilegua National Park, in Argentina. Furthermore, is locally common in young successional vegetation on river islands and along river floodplains and is well adapted for using an ever-shifting mosaic of habitats, both on islands and on adjacent mainland.

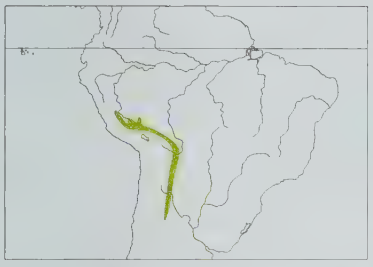
36. Buff-bellied Tanager

Thlypopsis inornata

French: Tangara à ventre roux **German**: Braunbauchtangare **Spanish**: Tangara Sencilla

Taxonomy. *Nemosia inornata* Taczanowski, 1879, Tambillo, Cajamarca, Peru.
May form a superspecies with *T. sordida*. Monotypic.
Distribution. Extreme SE Ecuador (extreme upper Marañón drainage near Zumba, in S Zamora–Chinchipe) and NC Peru (middle and upper R Marañón and upper R Huallaga/R Utcubamba, in W Amazonas and Cajamarca).



Descriptive notes. 13 cm; 14–17 g. Rather plain thin-billed tanager with rufous cap. Male has crown and nape rich dark cinnamon-rufous, contrasting with uniformly olive-grey upperparts including back, rump, uppertail-coverts; upperwing-coverts olive-grey, tinged brownish, primary coverts dusky; flight-feathers dusky, outer feathers narrowly edged greyish-olive, inner feathers edged and tinged brownish; tail olive-grey with brownish tinge; forehead, lores, ocular area, cheek, throat and underparts pale orange-buff, centre of belly and undertail-coverts whitish with buff tinge; iris dark brown; bill dark grey to blackish, often paler and bluer on lower mandible; legs horn-grey. Female is similar to male but duller, with crown and nape much duller, olive-grey with cinnamon tinge, and not contrasting strongly with upperparts; ear-coverts more strongly tinged cinnamon, rest of face and underparts buff with orangish tinge. Immature is similar to female, but upperparts mostly greyish-olive, underparts yellowish. Voice. Dawn song a thin, high "ti, sit, seet seet, suueet suueet, seet seet seet, sit sit" or similar variation, "suueet" notes higher-pitched, drawn out and forced; entire song high-pitched, leisurely in pace, and somewhat variable, sometimes without clear ending. Call a thin "sip" or "seep" during foraging; also "seet-a" repeated softly several times.
Habitat. Dry, shrubby semi-arid second growth, light canopy of dry forest, dry scrub and brush along rivers and ravines, and brushy clearings. At c. 450–2000 m in Peru, also sightings to 2200 m above Balsas (in upper Marañón Valley); 650–1200 m in S Ecuador. May meet or overlap in range very locally with *T. ornata*, but in general favours drier habitats at lower elevations.
Food and Feeding. Mostly small arthropods. Occurs in pairs and in small family groups. Forages at various heights, often quite near ground, and ranges out into tall grass and low shrubs; also well up in tree canopy in dry woodland. Movements fairly active, somewhat like those of a New World warbler (Parulidae). Gleans items from leaves, especially from outer leaves of acacia (*Acacia*), and leaf clusters, and has been seen regularly to check small dead or dry leaves and small clusters of dead leaves; occasionally probes or inspects flowers.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Marañón Valley EBA. Uncommon to locally fairly common. Utilizes dry woodland and secondary and degraded vegetation communities that are, at present, under pressure for conversion to agriculture only in a few areas where irrigation for rice-growing is possible. There appear to be few or no reserves within the tiny range of this species.
Bibliography. Clements & Shany (2001), Dorst (1957a), Fjeldså & Krabbe (1990), Isler & Isler (1999), Lysinger *et al.* (2005), Meyer de Schauensee (1966, 1970a), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Taczanowski (1884), Zimmer (1947a).

37. Rust-and-yellow Tanager

Thlypopsis ruficeps

French: Tangara à ventre jaune **German**: Goldkappentangare **Spanish**: Tangara Alisera

Taxonomy. *S.[ylvia] ruficeps* d'Orbigny and Lafresnaye, 1837, near Palca, Apupaya ("between Cochabamba and Incasivi"), Bolivia. Monotypic.
Distribution. Andes from SC Peru (E slope from Ayacucho, Apurímac and Cuzco) S through Bolivia to NW Argentina (vicinity of Tucumán).
Descriptive notes. 12 cm; 9·6–13 g. Small, brightly coloured thin-billed tanager. Male has crown, side of head to below eye, and malar area bright rufous, upperparts, including uppertail-coverts and upperwing-coverts, contrastingly bright olive-green; primary coverts blackish; flight-feathers dusky, edged bright olive-green, tertials dusky with olive-green outer webs, tail olive-green, slightly duller than upperparts; central throat and underparts bright yellow, sides and flanks tinged olive; iris dark brown; bill dark grey to blackish, often paler and bluer on lower mandible;

legs horn-grey. Female is similar to male, but duller, forehead and ocular area buffy yellow, tinged rufous, middle crown to nape mostly olive (like back). Immature is much duller and less distinctive than adult, rather like a *Basileuterus* warbler in appearance, mainly olive-green above, with ill-defined yellowish eyebrow, yellowish facial area may show tinge of fulvous colour, yellow below, olive sides and flanks. VOICE. Song, sometimes as duet, a short burst of chittering notes, similar to that of *T. sordida*. Utters soft "sit" and "tzit" notes when foraging.

Habitat. Bushy second growth and forest borders in humid areas, borders of cloudforest, *Chusquea* bamboo, and occasionally in patches of *Polylepis* woodland; humid sections of yungas forest at S end of range in Bolivia and N Argentina. In all areas favours low shrubbery. Generally at c. 1500–3700 m in Peru and Bolivia, but most records at 1850 m or higher; occurs at slightly lower elevations in NW Argentina.

Food and Feeding. Eleven stomachs contained only insects. Occurs alone, in pairs, and in groups of up to 5–6 individuals, often associated with mixed-species flocks containing New World warblers (Parulidae), other tanagers and emberizids. Moves quickly and restlessly, always on the go, and usually in rather thick low shrubbery, where difficult to see for more than a moment. Median foraging height 3 m, rarely above 9 m. In Bolivia, 86% of 40 foraging observations were of birds searching leaves, primarily taking prey from undersides of leaves; also searched flowers, dead leaves and branches, and a majority of prey items were taken without acrobatics (56%) or by reaching. In Peru took prey from foliage and flowers, and gleaned bamboo leaf bases and internodes.

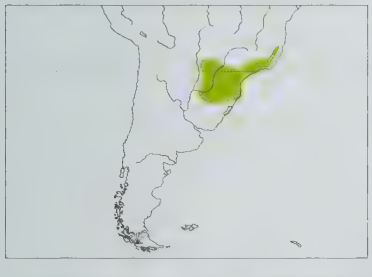
Breeding. Juveniles seen in Jun (Cuzco) and May and Jul (Puno) in Peru, and in Feb (La Paz) and May (Cochabamba) in Bolivia; fledgling in Jan in NW Argentina (Jujuy). No other information.

Movements. Appears to be at least partially migratory in extreme S of range (vicinity of Tucumán, in Argentina); over rest of range no seasonal movements reported.

Status and Conservation. Not globally threatened. Fairly common to locally common throughout range. Record from Martín García I (off NE Buenos Aires), in E Argentina, presumed to have involved a vagrant; isolated record from Huánuco, in C Peru, well N of normal range, may have involved a wandering individual or an erroneous identification. Occurs in a number of protected areas scattered along E face of Andes, including Manu National Park (Peru), Madidi, Isiboro Sécure, Carrasco and Amboró National Parks (Bolivia) and Calilegua National Park (Argentina). In addition, there are extensive areas of appropriate contiguous habitat in this species' range that are not protected, but appear not to be under immediate threat.

Bertonatti *et al.* (1994), Clements & Shany (2001), Dinelli (1918), Fjeldså & Krabbe (1990), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Morrison (1948), Moynihan (1979), Narosky & Yzurieta (1987), de la Peña & Rumboll (1998), Remsen (1985), Remsen *et al.* (1987), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Walker (2001), Weske (1972), Zimmer (1947a).

Genus *PYRRHOCOMA* Cabanis, 1851



38. Chestnut-headed Tanager

Pyrrhocoma ruficeps

French: Tangara à tête marron **German**: Zimtkopftangare **Spanish**: Tangara Pioró

Taxonomy. *Tachyphonus ruficeps* Strickland, 1844, Rio de Janeiro(?), Brazil.
Monotypic.

Distribution. NE Argentina (Misiones) and SE Paraguay E to SE Brazil (Espírito Santo S to C Rio Grande do Sul).

Descriptive notes. 14 cm; mean 15·6 g. Small, rather slight and slender tanager with strong bill and contrasting head. Male has head and throat dark chestnut, with black forehead, ocular area and chin (forming small rounding mask); otherwise dark grey above and below, upperwing-coverts dusky, broadly edged dark grey, primary coverts blackish; underparts slightly paler than upperparts, with centre of lower breast and belly greyish-white (not in strong contrast to rest of underparts); iris dark brown; bill blackish above, mostly blue-grey below; legs dark grey. Female is much duller than male, mainly brownish-olive above, with crown and nape pale dull rufous, lores and chin buff, side of head dingy greyish-buff with tinge of cinnamon; throat and underparts dull greyish-buff with olive tinge, palest on belly. Immature male resembles female, and may retain this plumage for considerable time; subadult male like female, but shows partially chestnut head and some grey in plumage. VOICE. Often noted first by voice. Song, usually from concealment in bamboo, of 3 high sibilant notes followed by 2 or 3 similar but slightly lower ones, e.g. "pseee-pseee-pseee, tweee-tweee-tweee", frequently repeated at c. 5-second intervals. Call a thin, light "tsick" and hissing "pseee".

Habitat. Dense undergrowth in forest, bamboo thickets, second growth and shrubbery along forest borders. From near sea-level to c. 1000 m in Rio Grande do Sul; mainly 1100–1400 m in Rio de Janeiro.

Food and Feeding. One stomach contained only insects. Seen mainly in pairs or families, and generally independent of mixed-species flocks. Forages mostly within 3 m of ground, more rarely to 8 m up. Inconspicuous, and typically stays in dense shrubbery and bamboo thickets, where difficult to observe. Behaviour recalls that of a *Buarremon* brush-finch.

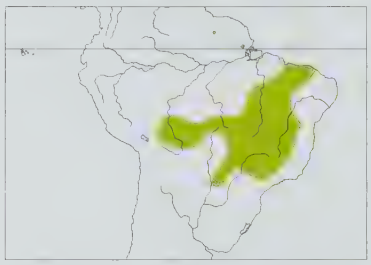
Breeding. Eggs white with a few dark spots, mostly at larger end. No other information.

Movements. Some movement inland during austral winter believed to occur.

Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in several national parks, including Ybycuí National Park (Paraguay), Iguazú National Park (Argentina) and Iguaçu, Itatiaia and Tijuca National Parks (Brazil). Over much of this species' range, however, relatively little suitable habitat remains outside reserves. Population trends undocumented and in need of investigation.

Bibliography. Belton (1985), Bertoni (1926), Burns (1997a), Burns *et al.* (2002, 2003), Capllonch *et al.* (2005), Diamond & Lovejoy (1985), Holt (1928), Ihering (1900), Isler & Isler (1999), Narosky & Yzurieta (1987), de la Peña & Rumboll (1998), Ridgely & Tudor (1989, 2009), Sick (1985, 1993), Souza (2002), Voss (1977a), Willis (1979).

Genus *CYPSNAGRA* Lesson, 1831



39. White-rumped Tanager

Cypsnagra hirundinacea

French: Tangara hirundinacé **German**: Weißbürzeltangare **Spanish**: Tangara Culiblanca

Taxonomy. *Tanagra hirundinacea*, Lesson, 1831, São Paulo, Brazil. Two subspecies recognized.

Subspecies and Distribution.
C. h. pallidigula Hellmayr, 1907 – NE Bolivia (W to W Beni) and C & E Brazil (from Humaitá, on R Madeira, E to SE Pará, N Maranhão, N Ceará and W Paraíba, and S to N Mato Grosso, N Goiás and W Bahia); isolated populations in S Suriname, S French Guiana and extreme NC Brazil (SC Amapá).
C. h. hirundinacea (Lesson, 1831) – E Bolivia, EC Paraguay (Laguna Blanca) and S Brazil (S Mato Grosso E to S Goiás and S Bahia, S to São Paulo).

Descriptive notes. 16–16·5 cm; 25–34 g. Boldly patterned tanager with fairly thick bill. Nominate race has head to just below eye, nape to upper back, uppertail-coverts and tail glossy black, lower back and rump white, rather wide white band on median coverts; upperwing-coverts glossy black, primary coverts black, flight-feathers blackish, white patch at base of primaries (outer webs of feathers white), basal two-thirds or more of outer primaries edged white (white conspicuous in flight); throat rusty amber, becoming creamy buff on underparts, palest on belly, and with flanks, thighs and undertail-coverts tinged cinnamon; iris dark brown; bill black; legs dark grey. Sexes similar. Immature has pattern echoing that of adult, but upperparts brownish and underparts creamy buff. Race *pallidigula* is similar to nominate, but has pale buff supraloral stripe (usually), also paler below, with buffish-ochre throat, whiter underparts. VOICE. Song, heard mainly prior to sunrise, a fast, loud series of melodic whistles with liquid quality, "whew chid-di-di-wee-wee-tyóó chid-d-o-wóó chi-d-dee-tyóó", the 3–6 phrases usually ending emphatically, and given over and over in rapid succession by pairs in antiphonal or synchronized duet. Female also may accompany male with simple "cha, cha, cha..." or more melodious "chewluh, chewluh, chewluh...". Songs, mostly from high in bush or tree, c. 5–10 seconds long, with short variable pause of c. 2–6 seconds between. Call of both sexes a low "kwet", "chat", and rattle.

Habitat. Primarily grasslands with scattered low trees and shrubs up to c. 2–5 m tall. In E Bolivia found in similar habitat and also in somewhat more wooded situations consisting of open woodland with dense grass and some scrubby undergrowth (*campo sucio*), as in S Los Fierros savannas of Noel Kempff Mercado National Park. May occur also in agricultural areas and edges of settled areas if enough suitable open terrain exists; has been reported also at woodland edges and in *Mauritia* palm groves within savannas. Recorded to c. 1000 m in Brazilian tablelands and to 700 m in Bolivia.

Food and Feeding. Mainly insectivorous, but reported also as eating fruit of *Annona*, *Byrsonima*, *Eugenia* and *Erythroxylum*. In C Brazil food items included beetles (Coleoptera), orthopterans, and alate ants (Formicidae) and termites (Isoptera); observed while taking large orthopterans (4–5 cm long) and a 3-cm caterpillar. Stomachs of four birds contained animal matter, including a large spider (Araneae) and a small beetle, and seeds. In C Brazil most often in pairs or trios, occasionally up to six together, even in breeding season, groups occupying territories of c. 5 ha; observations at Amos National Park (Brazil) and Noel Kempff Mercado National Park (Bolivia) have almost always been of pairs or trios, latter consisting of adult pair and an offspring. Pair strongly territorial, and quick to sing and duet to announce territorial ownership; at least in Bolivia, territories appear to be much larger than the 5 ha reported in Brazil. In C Brazil foraged low in vegetation and on ground, and opportunistically sallied to air for flying ants and termites. Hops slowly and methodically along interior branches of scrubby trees and peers with head and neck outstretched. Seen to take large orthopterans and a caterpillar from inside a curled green leaf and from beneath a leaf.

Breeding. In Brazil nesting recorded in Sept and Nov in Goiás and Nov in São Paulo. Co-operative breeder; one or two offspring from previous broods often assist with nesting duties. Nest a tightly woven cup of grass, occasionally with some leaves or twigs, sometimes lined with soft cotton-like plant material (of *Eriotheca*), placed 1–2 m above ground in low fork in small tree. Clutch 3–4 eggs, usually 4, pale blue, sparsely spotted with black or dark brown dots, these forming wreath at larger end; no information on incubation and nestling periods.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Fairly common locally. Occurs in several large protected areas, among them Noel Kempff Mercado National Park (Bolivia) and Das Emas and Brasília National Parks (Brazil). Extensive deforestation and land alteration have destroyed much habitat within this species' range, and continue to do so. Present population represents only a small percentage of the original. The species is worthy of monitoring.

Bibliography. Belton (1985), Burns (1997a), Burns *et al.* (2002, 2003), Cavalcanti & Pimentel (1988), Haverschmidt & Mees (1994), Hellmayr (1910), Holt (1928), Isler & Isler (1999), Naumburg (1930), Pelzeln (1869), de la Peña & Rumboll (1998), Ragusa-Netto (1997, 2000, 2002b), Renssen (1974), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Sick (1985, 1993), Snethlage (1914), Souza (2002), Tostain *et al.* (1992), Voss (1977a).

Genus *NEPHELORNIS* Lowery & Tallman, 1976

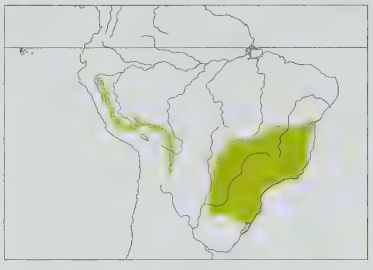
40. Pardusco

Nephelornis oneilli

French: Pardusco d'O'Neill **German**: Brauntangare **Spanish**: Tangara Pardusca

Taxonomy. *Nephelornis oneilli* Lowery and Tallman, 1976, Bosque Unchog, on pass between Churubamba and Hacienda Paty above Acomayo, c. 3592 m, Huánuco, Perú.
Taxonomic affinities initially unclear, and had been suggested as being closely related to New World warblers (Parulidae); investigations of cytochrome *b* sequence data, however, indicate that it is related to a clade of mostly Andean tanagers in genera *Hemispingus*, *Cnemoscopus*, *Pyrrhocoma*, *Thlypopsis* and *Cypsnagra*. Monotypic.
Distribution. E slope of Andes of Peru in San Martín, La Libertad, Amazonas (Kuelap), and Huánuco (E of R Huallaga near Panao, and W to Cordillera Carpish).

Descriptive notes. 12·5 cm; male 16–19 g, female 13·5–15·5 g. Small, plain tanager with short, pointed and fairly thin bill, reminiscent of a New World warbler (Parulidae). Has crown, lores, side of head and upperparts, including uppertail-coverts, plain brown, eyering slightly paler than face; greater upperwing-coverts dull brown with ochraceous-tawny tips (faintly indicated wingbar); flight-feathers blackish-brown, faintly edged basally with tawny-olive; tail blackish-brown, outer web of each feather edged light brownish-olive; below, ochraceous to dull tawny ochraceous, throat slightly paler and shading to light buff; flanks and undertail-coverts slightly darker than belly; iris warm brown to dark brown; upper mandible dark brown to horn-coloured, lower mandible flesh-coloured; legs light brown, soles yellowish. Sexes similar. Immature male is similar to adult, but darker brown throughout, and with wing-coverts, flight-feathers and tail feathers almost completely lacking pale edgings. Voice. Group-members constantly utter thin "seep" contact calls while foraging. Also gives soft "chip" note. Possible song a series of weak, high and jerky warbled phrases.
Habitat. Isolated and semi-isolated patches of wet elfin woodland (c. 4–10 m in height), low trees and bushes, and shrubs 1–2 m tall growing in *Sphagnum* bogs and wet grassland; irregularly up to limit of tree growth. Most woody vegetation in habitat supports a wide variety of epiphytic growth, especially moss and lichens. Recorded at c. 3000–3800 m; this zone often shrouded in fog and mist for parts of each day, especially during Nov–Apr rainy season.
Food and Feeding. Arthropods make up all or most of diet. Contents of four stomachs were remains of a spider (Araneae) and parts of Lepidoptera, beetles (Coleoptera), homopteran bugs and flies (Diptera); also a small amount of fibrous plant material. Occurs in monospecific flocks of 5–15 individuals, and sometimes with mixed-species flocks of *Conirostrum*, *Diglossa* and other tanagers. Active, constantly on the move and, once found, rather easy to see; individuals and small parties move from bush to bush much in the manner of bushtits (*Psaltriparus*) in North America. Forages by flying into middle part of bushes, and then working upwards and outwards on to limbs; shrubs and small trees with dense crown of clustered small leaves are preferred foraging sites, where it peers from side to side and gleans small arthropods from lower and, less frequently, upper leaf surfaces and stems, then rapidly moves or flies to another site. Probes moss and lichens. Foraging posture usually upright, but occasionally may hang with head downwards or extend its legs to reach more distant surfaces. Groups may follow other birds into canopy of trees, but, in general, prefer low wooded edge.
Breeding. No information. Female reportedly had an old brood patch, but specimen showed no postnuptial moult.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in North-east Peruvian Cordilleras EBA. Locally fairly common. Despite small, patchy distribution and restricted habitat preference (wet tree-line regions), this species is fairly common in places; it occurs mostly in remote areas that are sparsely inhabited by humans. Possibly occurs in Cordillera Azul National Park. Current threats include deforestation, fires and, especially, firewood-cutting, which has continued for centuries and has gradually reduced and fragmented much tree-line habitat, including that within the range of this tanager. May be vulnerable to habitat loss in the longer term.
Bibliography. Bledsoe (1988), Burns (1997a), Burns *et al.* (2002, 2003), Clements & Shany (2001), Fjeldså & Krabbe (1990), Horváth (1977), Lowery & Tallman (1976), Raikow (1978), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007).



Genus *TRICHOTHRAUPIS* Cabanis, 1851

41. Black-goggled Tanager

Trichothraupis melanops

French: Tangara à front noir **German**: Schwarzgesichttangare **Spanish**: Tangara de Anteojos

Taxonomy. *Muscicapa melanops* Vieillot, 1818, Paraguay.
Recent molecular-genetic studies suggest that genus is most closely related to *Eucometis* and to *Tachyphonus surinamus* and *Lanio*, that it and *Eucometis* are sister-genera, and that *Coryphospingus* and *Rhodospingus* (both currently placed in Emberizidae) also are members of this clade. Present species consists of two geographically well-separated populations, one montane and the other primarily lowland; investigation required in order to determine whether these represent distinct taxa. Currently treated as monotypic.
Distribution. Narrowly along E slope of Andes from N Peru (S from S Amazonas and San Martín) S to Bolivia and N Argentina (N Jujuy); SE Brazil (S Mato Grosso, S Goiás and S Bahia S to N Rio Grande do Sul) and adjacent NE Argentina and E Paraguay (E of R Paraguay).

Descriptive notes. 16 cm; 16–26 g, 21·7–29·5 g (Brazil). Male has a black mask extending from forehead back onto broad patch around eye; yellow crown patch (usually concealed, or showing only as narrow yellow stripe); rear crown and nape to uppertail-coverts dark olive-grey with brownish tinge; upperwing-coverts dusky, primary coverts, flight-feathers and tail blackish; white band or patch at base of secondaries and white band in centre of primaries, the two forming broken wingband (white usually not visible when bird at rest); throat and underparts buff, paler on centre of belly, undertail-coverts tinged buffy cinnamon; underwing-coverts white; iris dark reddish-brown; bill blue-grey, often duskier on most of upper mandible; legs greyish-horn. Female is similar to male, but duller, with no yellow crown patch, little or no black on face and side of head, and less contrast between back and wings. Juvenile undescribed. Voice. Two song types described in Brazil: the first a rambling series of slurred whistles mixed with musical notes, "puu-eee, wa-é-wa-é, whur whur, j-eep, whit? pheee peee", which may include sweet and warbled notes, often mixed with harsh call notes; the second a long series of more varied notes and squeaky notes, also with slurred whistles, buzzy notes and short "psp" notes, in which the same note may be repeated 2–5 times. Frequently heard calls include burry "tswick" or "twzt" and high "tst". Andean population seems unusually quiet.
Habitat. In Andes found mainly in humid forest borders and forest light-gaps with thick undergrowth; c. 1000–1700 m in Andes, but as low as 300 m in foothills in Bolivia. E population in semi-open shrubby areas, forest borders, riparian woodland, second growth in clearings and, in SE Brazil, isolated woodlots as small as c. 21 ha; lowlands to c. 1500 m in SE Brazil, Paraguay and NE Argentina.
Food and Feeding. Of 31 stomachs examined, six contained only vegetable matter and 22 only animal matter, and three contained both; contents included beetles (Coleoptera), fruit, seeds, and pieces of shell of a snail (Pulmonata). Noted also as eating butterflies (Lepidoptera) and wasp larvae (Vespidae); in Paraguay reported as eating *Allophyllus edulis* fruits 7–10 mm long. Found in pairs and at times in small family groups, occasionally in larger groups of up to a dozen; regularly forages with mixed-species flocks, especially in Andes, and regular at army-ant (Formicidae) swarms in Brazil. Rather active and restless, frequently hopping from branch to branch and up through vine tangles; sallies to foliage or to air, mostly rather low, and occasionally drops to ground or ascends into tree crown for fruit. In Paraguay foraged mostly in dense foliage of tree crown, but also in all other parts of tree; reached out, leaned over, or made quick sallies to pick fruit, rarely hovered; rolled fruit in bill to remove exocarp, and dropped seeds or swallowed entire fruits.
Breeding. Breeding recorded in Brazil in Oct (São Paulo) and Nov (Rio de Janeiro). In SE Brazil, a cup-nest was 1 m up in bamboo in forest, contained 3 young. Eggs pinkish-white marked with brown, lavender and black, especially at large end. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Andean population uncommon and local; E population generally more numerous, and considered abundant in mountains of Espírito Santo and Rio de Janeiro (Brazil). Found in several protected areas in Andes, including Manu Biosphere Reserve, in Peru, and Madidi, Carrasco and Amboró National Parks, in Bolivia. Extensive intact, unprotected habitat also remains within this species' range in Andes. E population also occurs in numerous parks and reserves, including Serra da Bocainá, Itatiaia, Tijuca, Serra dos Órgãos, Caparaó and Iguaçu National Parks and Augusto Ruschi (Nova Lombardia) Biological Reserve, among others, in Brazil, and Iguazú National Park, in Argentina. In much of SE Brazil, deforestation is so complete that most of the unprotected habitat within the former range of this species has disappeared, and it is now confined largely to parks and reserves. Despite extensive range contraction and fragmentation in Brazil, this tanager seems not to be at risk and may even profit locally from bushy regrowth.
Bibliography. PLATE 4 ➤

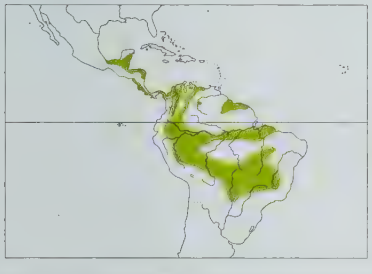
PLATE 4

inches 3
cm 8



Genus *EUCOMETIS* P. L. Sclater, 1856

42. Grey-headed Tanager

Eucometis penicillata

French: Tangara à tête grise **German**: Graukopftangare **Spanish**: Tangara Cabecigrís
Other common names: Grey-crested Tanager (*cristata*)

Taxonomy. *Tanagra penicillata* Spix, 1825, no locality = Fonte Boa, Amazonas, Brazil.
Recent molecular-genetic studies suggest that this genus and *Trichothraupis* are sister-taxa. Marked geographical variation in size and plumage; also, genetic analyses have shown that, while two individuals from adjacent sites in Bolivia (race *albicollis*) differed in sequence divergence values of only 0·35%, populations from Middle America differed from Bolivian ones by 4·8%, as much as or more than that between many passerine taxa now recognized as separate species. Further study needed. Seven subspecies recognized.
Subspecies and Distribution.
E. p. pallida Berlepsch, 1888 – SE Mexico (on Caribbean slope from S Veracruz, N Oaxaca, and Yucatán Peninsula), N & C Guatemala, Belize and N Honduras (S to Olancho).
E. p. spodocephalus (Bonaparte, 1853) – both slopes of Nicaragua S to Costa Rica (S on Pacific slope to Guanacaste and on Caribbean slope to Alajuela).
E. p. stictothorax Berlepsch, 1888 – Pacific slope of Costa Rica (S from Puntarenas) S to Panama (Veraguas).
E. p. cristata (du Bus de Gisignies, 1855) – Panama (Caribbean slope from Coclé E to C Panama, and Pacific slope E from Veraguas) E to Colombia (S in Cauca Valley to Valle, and in Magdalena Valley to Huila; also E of Andes in Arauca), and NW Venezuela (E to Mérida and extreme W Portuguesa).
E. p. affinis Berlepsch, 1888 – N Venezuela from Falcón E to Miranda.
E. p. penicillata (Spix, 1825) – E of Andes from Colombia (Meta and Amazonas) S through E Ecuador to Peru (Ucayali), and E across much of NC Brazil to Atlantic (W Maranhão); also S Venezuela (NW Amazonas) and the Guianas.
E. p. albicollis (d'Orbigny & Lafresnaye, 1837) – E of Andes from N Bolivia (Pando, La Paz and Santa Cruz) E across C Brazil (Mato Grosso E to Minas Gerais and W São Paulo); also NE Paraguay (sight record Concepción).

Descriptive notes. 16–17 cm; 22·5–35 g. Nominate race has grey head, large bushy crest (white at feather bases usually concealed); upperparts including uppertail-coverts yellowish-olive, upperwing-coverts olive, tinged yellowish; primary coverts and flight-feathers dusky, edged yellowish-olive, inner flight-feathers and tertials mostly yellowish-olive with dusky inner webs; tail olive with yellowish edges; chin and throat whitish, fairly well demarcated from rich yellow underparts; iris reddish-brown; bill blackish; legs pale greyish-pink. Sexes similar. Immature is like adult, but lores dusky, and head and throat yellowish-olive like upperparts. Races differ mainly in size, in prominence of crest and in darkness of plumage: *pallida* is slightly smaller than nominate, with head and throat somewhat darker grey, no white in crown; *spodocephalus* is similar to previous, but slightly darker, and with orangish-yellow wash on chest; *stictothorax* is very like last, but with faint olive streaks/spots on breast; *cristata* has darker head, very pale grey throat with slight olive tinge, and shorter crest with little or no white at base; *affinis* is very like preceding race, but crest even shorter, and throat lacks olive tinge; *albicollis* has longish buffish-grey crest, buff-tinged throat, also pinkish or pinkish-grey bill. Voice. Songs may vary somewhat geographically (or possibly individually), but are typically high-pitched and sputtering. In Costa Rica a high, thin, rather sibilant medley, "whichis, whichis, whichis, whicheery whichis whichu", "tsee tseep SEEUr tsp-tsp tseeur tsp-tsp seeur ts-suur...", and similar; in Panama a musical "sputter, eat eat meat chop", "safurry chew, safurry chew..." or the like; in Brazil, a series of high whistles, descending near end, "tzee, tzee, tzee, zi, zi, zi, zi, zi, zi", sometimes longer or varied. Has variety of sharp unmusical call notes: in Mexico calls described as a high, sharp "siip" and "ssi-ssip", at times run into slightly lisping twitter, also a low, hard, clipped "tk" or "tuk" and soft clucking "ichik chik"; in Costa Rica as a high, thin "chip" or "pit", sometimes repeated incessantly, and high squeaky "tseeet", often repeated 2–3 times; in Colombia (Amazonas) alarm a sharp "schip".
Habitat. Varies over broad range. In N of range and W & N of Andes occurs in undergrowth of both dry and humid forest, especially in areas with dense shrubbery, as well as in gallery forest, forest borders and second-growth woodland of various ages, but in dry areas favours moister sites, such as along rivers. In NW South America also locally in low-elevation cloudforest, e.g. in coastal range of N Venezuela. In Amazonia, nominate race mainly in undergrowth of *várzea* forest and other low or poorly drained wooded sites, whereas S race (*albicollis*) occurs in undergrowth of tall moist forest (including gallery forest) and bushy forest borders and is often found near watercourses. Sea-level to 1700 m, mostly below c. 1000 m.
Food and Feeding. Arthropods; also fruit, including *Miconia* berries, arillate seeds etc. Nestling diet mostly insects. Found singly and in pairs in drier, more marginal sites, but may gather in much larger groups, sometimes of up to 15 individuals, over army-ant (Formicidae) swarms in humid areas N & W of Andes. In latter regions forages over army ants or away from them with equal facility; E of Andes seems infrequently associated with army ants, but S race *albicollis*, at least in Santa Cruz (Bolivia), seems to be again a regular follower of raids. Stays mostly in shady undergrowth and often somewhat wary, at least initially. Over ant swarms behaves in restless, active manner, often flicking wings and tail, and taking arthropod prey by sallying rapidly to the ground or substrate, or reaching and pecking prey from a perch. In all areas most foraging is from near ground level to c. 5 m up, more rarely much higher.
Breeding. Breeding reported in Apr in Belize; breeds Mar–Jul (two broods) in Costa Rica and Apr–Sept in Panama; nest under construction in Feb in Colombia (Reserva Reinita Cielo Azul, in Santander); breeding reported Feb, Sept and Nov–Dec in NC Brazil (Pará). Nest material brought by both sexes, both also build nest, taking 2–3 days, sometimes up to 6 days; a frail, thin-walled, shallow cup of rootlets and plant fibres, often lined with hair-like fungal rhizomorphs, typically c. 10 cm in outside diameter and 6 cm deep, placed 0·5–3 m (usually 1·5–2·1 m in Costa Rica) above ground in bush or tree at edge of or outside forest, especially alongside water or in isolated bush such as coffee shrub (20 nests reported in coffee), often in spiny palm in forest (e.g. in Costa Rica), more rarely in tall grass or in vines near forest; one nest in Colombia was in dense mass of exposed rootlets 1·8 m up and beneath cut roadbank in coffee plantation. Clutch 1–2 eggs, rarely 3, dirty white, grey or pale blue-grey or pinkish-buff, heavily mottled with brown (colour perhaps varying with race); incubation by female, in stints of c. 48–97 minutes, recesses of 20–55 minutes, constancy rate c. 62%, incubation period 14–16 days; chicks fed by both parents, nestling period 11–12 days. Of 24 nests of known outcome in Costa Rica, nine produced at least one young, giving success rate of 37·5%; main cause of failure was predation.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Variably uncommon and local in drier regions to common in some humid regions, especially N & W of Andes. Widespread across much of Amazonia, but much more numerous in some areas than in others. Primarily a forest-based species, although occurs also in second-growth woodland. Found in many protected areas, including Indio-Maíz Biological Reserve (Nicaragua), La Selva Biological Reserve and Braulio Carrillo and La Amistad National Parks (Costa Rica), Soberanía, Chagres and Darién National Parks (Panama), Los Katíos National Park (Colombia), Henri Pittier National Park (Venezuela), and various parks scattered over the Ecuadorian, Peruvian and Brazilian Amazon. The species is not likely to be at any near-term risk, although all of the Middle American populations have lost much of their former habitat outside unprotected areas and have undergone range contractions and suffered range fragmentation.

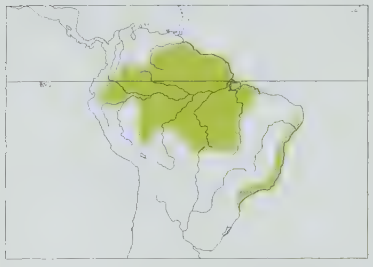
Genus *TACHYPHONUS* Vieillot, 1816



43. Flame-crested Tanager

Tachyphonus cristatus

French: Tangara à huppe ignée **German**: Haubentangare **Spanish**: Tangara Crestifuego
Other common names: Scarlet-crested Tanager; Natterer's Tanager (*nattereri*)

Taxonomy. *Tanagra cristata* Linnaeus, 1766, Cayenne, French Guiana.
Genetic data indicate that this species is sister to *T. rufiventer* and that *T. luctuosus* is sister to both of these. Present species exhibits marked geographical variation in plumage, with racial limits poorly defined. Very poorly known taxon *nattereri*, with distinctive male plumage, may represent a separate species but usually considered a race of present species or aberrant example of *madeirae*; a female specimen once thought possibly to be of *nattereri* was subsequently reassigned to *madeirae* (recent "discovery" of an additional specimen, presumably of *nattereri*, may shed light on this question). Taxonomic status of isolated E coastal race *brunneus* also worthy of investigation. Given the amount and complexity of variation within this species, and the fact that, conversely, differences between some races seem trivial, a full taxonomic review seems warranted. Ten subspecies currently recognized.
Subspecies and Distribution.
T. c. orinocensis J. T. Zimmer & Phelps, Sr, 1945 – extreme E Colombia and S & SE Venezuela (N & E Amazonas and W Bolívar E to R Paragua and R Caroní).
T. c. intercedens Berlepsch, 1880 – E Venezuela (E of R Caroní) E to Guyana and Suriname.
T. c. cristatus (Linnaeus, 1766) – French Guiana and NE Brazil (N of R Amazon and E of R Nhamundá).
T. c. cristatellus P. L. Sclater, 1862 – SE Colombia (from vicinity of Villavicencio, in Meta) and S Venezuela (SW Amazonas) S to extreme NW Peru and NW Brazil (S & E to Manaus).
T. c. fallax J. T. Zimmer, 1945 – S Colombia (SE Nariño), E Ecuador and N Peru (S to lower R Ucayali).
T. c. huarandosae Chapman, 1925 – Huarandosa (in Chinchipe Valley, near Marañón Valley) in N Peru.
T. c. madeirae Hellmayr, 1910 – C Brazil S of Amazon (from Teffé E to R Xingu and S into Mato Grosso), also adjacent SE Peru (E Madre de Dios) and adjacent N Bolivia (Pando and N Beni).
T. c. nattereri Pelzeln, 1870 – WC Mato Grosso (Villa Maria, near Cáceres), in SW Brazil.
T. c. pallidigula J. T. Zimmer, 1945 – NE Brazil (Pará and lower R Tocantins).
T. c. brunneus (Spix, 1825) – E Brazil from Rio Grande do Norte S, discontinuously, to NE Santa Catarina; possibly also Maranhão E to Paraíba.
Descriptive notes. 15 cm; 16·6–23 g. Canopy-dwelling tanager with fairly short thick bill and small orangish to red bib; crest often less impressive than its vernacular name suggests. Male nominate race is mainly glossy black above and below, with broad, flat crest bright orange, paler in front; rump and uppertail-coverts yellow-buff, upperwing-coverts, flight-feathers and tail black, white patch on outermost scapulars (often hidden); centre of throat straw to dull buffy orange, underwing-coverts white; iris dark reddish-brown; bill black, base of lower mandible blue-grey; legs horn-grey. Female is generally olive to rufescent brown above with richer brown crown, rich ochraceous below, with whitish to buff-white throat and faint narrow buff eyering. Juvenile undescribed. Races differ mainly in colour of crest and in size and colour of male's throat patch (smallest in NW races), also those N of Amazon have deeper black plumage than those S of river (except for *nattereri*): *intercedens* differs from nominate in having rump pale yellow-orange, also pale orange crest with

On following pages: 44. Yellow-crested Tanager (*Tachyphonus rufiventer*); 45. Fulvous-crested Tanager (*Tachyphonus surinamus*); 46. White-shouldered Tanager (*Tachyphonus luctuosus*); 47. Tawny-crested Tanager (*Tachyphonus delatrii*).

deep orange centre and yellow-orange bib (Gran Sabana of Venezuela), variable, crest rich yellow and bib dull yellow in Imataca region of Venezuela, and crest pale yellow with greyish-yellow bib in Guyana, female is much paler below than nominate, has no rufous tinge above; *orinocensis* has "bicoloured" crest, with front and sides bright yellow and centre and rear bright red, central throat patch pale orange, upper rump yellow and lower rump becoming orangish, female differs from nominate in warmer rufous-brown upperparts, darker brown crown, more greyish (not dull buff) throat and brighter underparts; *cristatellus* has crest entirely scarlet (the reddest of all races N of Amazon), central throat patch dull buff-orange, female is more rich yellow-buff below; *fallax* is similar to nominate, but tail slighter shorter, crest more orange (less scarlet), and with buff frontal band not so well developed; *huarandosae* is much like nominate, but crest much longer (longest of all races) and more orange; *madeirae* has crest the richest red of all races but relatively short, also has notably long wing and tail, and bend of wing blackish (but underwing white, as on all races), female more reddish-brown than that of nominate; *pallidigula* is similar to previous, but throat and rump paler, female like previous; *brunneus* differs from *madeirae* in having crest unusually long and full and slightly paler red, also has all-white bend of wing (unlike *madeirae*), female like previous; *nattereri* has orange crest, completely lacks throat patch, and has deep black body plumage with larger white wing patch and smaller buff rump patch. Voice. Thin "seeep" and "chet" notes during foraging. Song at Alta Floresta (Brazil) a rather uninspired and irregular series of up to c. 20 fairly high-pitched repetitive notes, each inflected upwards, "pseet!, pseet!...pseet-pseet!, pseet!, pseet!, ...", c. 1 note per second, the series on even pitch.

Habitat. Over most of Amazonian range found in *terra firme* forest and in tall old second growth; less often in *várzea* forest. In E & SE Brazil, geographically isolated race *brunneus* reported as favouring forest edge, open woodland, gallery and savanna forest, and second growth, rather different from preferred habitats in Amazonia. Lowlands to c. 1400 m in Venezuela, to 500 m in Colombia, locally to 1000 m in Ecuador and 800 m in Peru.

Food and Feeding. Mostly arthropods and fruit. Of eight stomachs examined, four contained only vegetable matter and two only animal matter, and two contained both; contents included fruit, berries, seeds, and insect remains. Contents of other stomachs included short-horned grasshoppers (Acrididae). In all areas found in pairs or small family parties, occasionally singly or in groups of up to six individuals, rarely to ten; associates with fast-moving canopy and subcanopy mixed-species flocks, of which it is a core member (over much of Amazonia most canopy flocks have a pair or family of present species). Forages mainly in canopy, but often drops lower to fruiting trees and shrubs; in fruiting trees stays mostly in outer foliage. Active and restless, seems always to be on the go, hopping quickly along slender, horizontal canopy branches and out into terminal foliage, gleaning arthropods from foliage, flutter-chasing or sallying in foliage, hopping in vine tangles, or reaching down, or even hanging downward occasionally, then pausing momentarily (as if to catch its breath), before rushing off to a fruiting tree. Because of restless behaviour is not an easy bird to observe at length.

Breeding. One in breeding condition on 25th Jan in Colombia (Macarena Mts). Nest reported as being a small open cup placed in bush or small palm near stream or pond in forest understorey (verification needed). Eggs white to yellowish-pink, spotted red and sometimes stained black. No other information.

Movements. Apparently resident in all areas. Seasonal movements possible in extreme S parts of range in SE Brazil.

Status and Conservation. Not globally threatened. Widespread and typically fairly common. Occurs in many protected areas, including e.g. Canaima National Park (Venezuela), Iwokrama Wilderness Reserve (Guyana), Voltzberg National Park (Suriname), and numerous parks in E Colombia, E Ecuador and Amazonian Brazil. Range also encompasses extensive areas of intact habitat, which, although not formally protected, are at low risk of development in foreseeable future. Isolated race *brunneus* in coastal SE Brazil found mainly in protected areas, such as Sooretama, Augusto Ruschi (Nova Lombardia) and Poço das Antas Biological Reserves, and Serra dos Órgãos and Tijuca National Parks. Deforestation extensive throughout SE Brazil, and *brunneus* may survive mainly in reserves and protected areas.

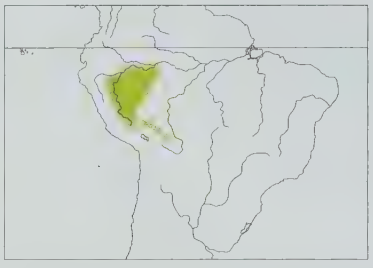
44. Yellow-crested Tanager

Tachyphonus rufiventer



French: Tangara à crête jaune **German**: Gelbschopftangare **Spanish**: Tangara Crestiamarilla

Taxonomy. *Tanagra rufiventer* Spix, 1825, São Paulo de Olivença, River Solimões, Brazil.

Genetic data indicate that this species is sister to *T. cristatus* and that *T. luctuosus* is sister to both of these. Monotypic.

Distribution. E Peru (S of R Marañón and R Amazon) and adjacent W Brazil (SW Amazonas and W Acre) S to NW Bolivia (La Paz).

Descriptive notes. 15 cm; 15·5–20 g. Dark-plumaged, slender canopy-dweller best told by small "bow-tie" enclosing narrow dark buff throat. Male has buffy-yellow crown patch of variable intensity (almost always concealed), rest of crown, side of head and nape to back, upperwing-coverts, flight-feathers and tail black, rump and uppertail-coverts contrastingly deep buff (usually hidden by wings); bend of wing and outermost scapulars white (often concealed); constricted dark yellow-buff central throat patch enclosed by short narrow black band across base of throat (intensity and completeness of black throatband variable, sometimes obscure); underparts rich tawny, sides and flanks yellow-buff (intensity of colour of underparts variable); iris dark brown; bill blackish with most of lower mandible greyish-blue; legs dark grey. Female is olive above, with slightly contrasting greyish crown and side of head; throat whitish, becoming ochraceous buff on underparts, and darker ochraceous buff, tinged cinnamon, on undertail-coverts; intensity of colour of throat and undertail-coverts variable. Immature male is like female, but crown olive, like back, and throat yellowish.

Voice. Calls rather high-pitched and easily overlooked, most likely to be heard when birds foraging with mixed flocks; include reedy or slightly shrill "jjit" and higher "zeep", the two often given in combination, e.g. "zeep? jjit jjit jjeep", also a high "tswee". A high buzzy "dzz-dzz-dzz" is possibly a song.

Habitat. Humid *terra firme* and *várzea* forest and forest borders. Lowlands to c. 1250 m in Peru, to 1650 m in Bolivia. In S Peru and adjacent Bolivia largely confined to hilly terrain and foothills, and replaced by *T. cristatus* in lowland forest.

Food and Feeding. Of two stomachs examined, one contained only vegetable matter and the other both vegetable and animal matter, including fruit pulp and a caterpillar. Found in pairs, sometimes with juveniles, and is a core member of canopy or middle-level mixed-species flocks. Active and rapidly moving, its behaviour is much like that of *T. cristatus*. Peers at foliage, picks insects from upper surface of leaves, and sallies short distances (less than 0·5 m) to upper surfaces of leaves.

Breeding. No information.

Movements. Resident. Data from SE Peru suggest that, once mated, pairs probably remain on a permanent territory throughout life.

Status and Conservation. Not globally threatened. Fairly common. Distributed primarily in W Amazonia. Occurs in several protected areas, including the Pacaya-Samiria National Reserve and Manu Biosphere Reserve (Peru), Madidi National Park (Bolivia) and Serra do Divisor National Park (Brazil); found also in numerous private reserves around eco-lodges in W Amazonia, e.g. Explorama, Explornapo and ACEER Lodges, near Iquitos, in Peru. Range encompasses large areas of intact forest, which, although not formally protected, is at low risk of deforestation in short term.

Bibliography. Burns & Racicot (2009), Hellmayr (1936), Isler & Isler (1999), Mee *et al.* (2002), Meyer de Schauensee (1966, 1970a), Munn (1985), O'Neill & Pearson (1974), Pearson (1971), Pinto (1944a), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Weske (1972), Zimmer (1945).

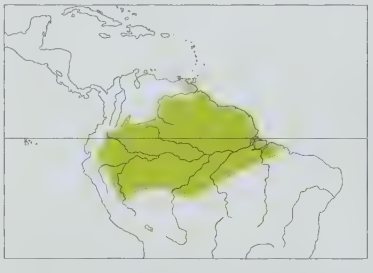
45. Fulvous-crested Tanager

Tachyphonus surinamus

French: Tangara à crête fauve **German**: Goldschopftangare **Spanish**: Tangara Crestifulva
Other common names: Napo Tanager (*napensis*)

Taxonomy. *Turdus surinamus* Linnaeus, 1766, Suriname.

Geographical plumage variation complex. Four subspecies recognized.



Subspecies and Distribution.

T. s. surinamus (Linnaeus, 1766) – E & S Venezuela (SE Sucre, E Monagas, Delta Amacuro, Bolívar and N & C Amazonas), the Guianas, and Brazil N of R Amazon (E from R Negro).

T. s. brevipes Lafresnaye, 1846 – SE Colombia (from Meta and Guainía) and S Venezuela (SW Amazonas) S to E Ecuador, NE Peru (N of R Amazon and R Marañón) and NW Brazil N of Amazon.

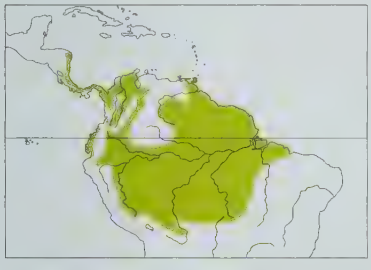
T. s. napensis Lawrence, 1864 – E Peru S of R Marañón (S to R Ucayali) and W Brazil S of R Amazon (E to Acre and R Juruá).

T. s. insignis Hellmayr, 1906 – Brazil S of Amazon (from R Madeira E to NE Pará).

Descriptive notes. 15–17 cm; 15–27 g. Canopy-dwelling tanager with fairly short, relatively thin bill. Male nominate race is mainly glossy black, with flat yellow-buff crown patch (often partly concealed), feathers of which can be raised as short crest; rump buff, bend of wing white, pectoral patch on side of chest (often partly concealed by bend of wing) buffy white, long flank feathers maroon-chestnut to carmine (usually forming protruding patch), underwing-coverts white; iris dark brown; bill blackish above, blue-grey below; legs dark grey. Female has mostly grey crown and side of head; conspicuous yellowish area around eye is rather variable, often broken by diffuse dusky line, and usually surrounded by olive; upperparts dark olive, throat and underparts buffy to greyish-white, breast tinged brownish, sides tinged greyish, and belly and undertail-coverts contrasting ochraceous. Juvenile like adult female but much duller and plainer; immature progressively more like adult, older males showing patches of black mottling, especially on head, mantle, chest and wings. Races differ primarily in colour of male's pectoral tufts, some also in colour of crown and flank patches: *brevipes* has white pectoral patch and dark rufous flank patch, also deep buff rump, female on average paler than nominate, underparts buffier, varying from cinnamon-buff or yellowish or orangish-buff, with flanks tinged olive; *napensis* is similar to previous, but male rump dark rufous; *insignis* resembles nominate, from which differs in darker, more tawny rump and paler, more tawny (not chestnut) flank patch. Voice. In SE Venezuela, infrequently heard song an extremely high, sibilant, almost hissing "sieeeee-siiiiiiii" (second part higher), or with one or two added "sii" notes at end; in Peru, described as a series of hummingbird-like screeches mixed with rich "chip" notes, e.g. "soo-see-soo-see'chip'chip soo-see-soo-see'chip...". Calls include high, weak "steep", varied to "steep-di-dit"; also very high "tseek-tseek-tseek" and buzzy rattle during foraging; also abrupt gravelly notes, e.g. "chur, chur-dit", and rattled "chu-di-di-di-dit".

Habitat. Interior of *terra firme* forest, especially in scrubby sandy-soil regions, lighter sandy-soil woodland, bushy forest borders, and scrub and bushy vegetation around large rocky outcrops; also, at least locally, in humid lowland *várzea*. Generally occurs in poorer-soil forests, in more bushy or semi-open areas, and in wider range of habitats than those in which allied *T. cristata* found. Lowlands to 1400 m in Venezuela; up to c. 500 m in Colombia, c. 900 m in Ecuador; 500 m in Peru.

Food and Feeding. Insects and small fruits. Of 20 stomachs examined, nine contained only vegetable matter and eight only animal matter, and thee contained both; contents included short-horned grasshoppers (Acrididae), fruit, berries, and seeds. Other stomachs contained bees (Hymenoptera), weevils (Curculionidae), caterpillars, bugs (Hemiptera, including homopterans), and craneflies (Tipulidae). Pairs or families follow mixed-species flocks in middle levels of forest, less frequently in high canopy (where *T. cristatus* occurs), and partial to shrubby forest edges or natural breaks in forest. Often at eye level or lower along forest borders and in bushes at edges of rocky outcrops.



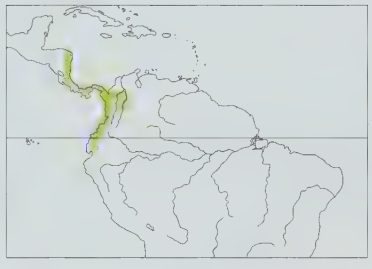
Energetic, nervous, and often seems to be constantly fidgeting; male flicks wings when excited, exposing the white flank patch momentarily (like a little winking light). Peers and flutters in foliage for insects. Not easy to observe at length.
Breeding. In Brazil nest reportedly a deep open cup, but nest location and egg details require verification. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Widespread and fairly common. Found in many protected areas and reserves, including Canaima National Park (Venezuela), Iwokrama Wilderness Reserve (Guyana), Voltzberg National Park (Suriname), and Pico da Neblina, Serra da Mocidade, Serra do Divisor and Viruá National Parks (Brazil), also Nukak Natural Reserve and Cahuinarí, Chiribiquete and Amacayacu National Parks (Colombia) and Pacaya-Samiria National Reserve (Peru); occurs also in various private reserves around eco-lodges, e.g. Junglaven, in S Venezuela (Amazonas), and Explorama and Explornapo Lodges, near Iquitos, in Peru. This species range encompasses large areas of intact forest not formally protected, but at low risk of deforestation in the immediate future, ensuring at least the short-term viability of this species.
Bibliography. Burns (1997a), Burns & Racicot (2009), Burns *et al.* (2002, 2003), Gilliard (1941), Haverschmidt (1968), Haverschmidt & Mees (1994), Hellmayr (1910), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Novaes (1970), Oren & Parker (1997), Pearson (1972), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sick (1985, 1993), Snethlage (1907, 1935a), Snyder (1966), Souza (2002), Tostain *et al.* (1992), Willis (1977), Zimmer (1945).

46. White-shouldered Tanager

Tachyphonus luctuosus

French: Tangara à épaulettes blanches **German**: Trauertangare **Spanish**: Tangara Luctuosa

Taxonomy. *T.*[*achyphonus*] *luctuosus* d'Orbigny and Lafresnaye, 1837, Guarayos, Bolivia.
Recent genetic data indicate that *T. cristatus* and *T. rufiventer* are sister-species, with present species sister to both. Five subspecies recognized.
Subspecies and Distribution.
T. l. nitidissimus Salvin, 1870 – Caribbean coast from E Honduras S to NW Panama (Bocas del Toro).
T. l. axillaris (Lawrence, 1874) – Pacific coast of Costa Rica (San José) S to Panama (W Chiriquí).
T. l. panamensis Todd, 1917 – C Panama (from Coclé) E on both slopes to N Colombia and W Venezuela (Maracaibo region), and S on Pacific coast to W Ecuador and extreme NW Peru.
T. l. flaviventris (P. L. Sclater, 1856) – extreme NE Venezuela (Sucre) and Trinidad.
T. l. luctuosus d'Orbigny & Lafresnaye, 1837 – E base of Andes from Venezuela (Barinas) S to N & C Bolivia, and generally from SE Colombia, S & E Venezuela (S of R Orinoco, and in Delta Amacuro and Monagas), the Guianas and Amazonian Brazil E to W Maranhão, S to Mato Grosso and W Goiás).



Descriptive notes. 13–14 cm; 11·5–15 g. Thin-billed tanager. Male nominate race is almost entirely glossy black, with conspicuous white patch on shoulder (marginal, lesser and median upperwing-coverts white), and white underwing-coverts; iris dark brown; bill blackish, basal half of lower mandible slightly paler; legs dark grey. Female is very different, has grey head, bright olive-green upperparts, including wing-coverts, greyish-white throat, and yellow underparts often tinged olive on breast; looks very like a smaller, uncrested version of *Eucometis penicillata*. Juvenile like adult female but much duller and more uniform; immature male progressively more like adult, older males darker, latterly showing patches of black, especially on head, mantle, wings and underparts, and white on shoulders. Race *nitidissimus* male has concealed yellow crown patch, white shoulder patch larger than on nominate, female is mainly olive above with grey tinge on crown, and has whitish throat and yellow underparts, and both sexes have base of lower mandible much paler, greyish-flesh; *axillaris* male has semi-concealed orange-and-cinnamon crown patch, shoulder patch larger than on nominate, female is like previous but with buff throat, and bill all dark; *panamensis* male has white shoulder patch larger than other races, female is brighter, more olive-green, above than nominate and has whiter chin and throat and brighter yellow underparts; *flaviventris* has small white shoulder patch (same size as on nominate), differs from nominate in slightly longer bill and wing. Voice. Song a thin, high "seet-seet-seet" (sometimes 4 or more notes), 2 notes per second, sometimes in series mixed with "seet" or "quick seet-seet" notes; rather weak and easily overlooked. Rather insignificant calls include high-pitched, sharp, almost hissing "tseer"; in Peru, weak call notes "swee" and lower "chep".
Habitat. In Central America and W & N of Andes found most often in tall older second growth and along forest borders; in Amazonia confined more to humid *terra firme* and *várzea* forest, where occurs in dense foliage and vine tangles above treefalls and at small openings in forest, also forest borders and older second growth. Recorded also in plantations in Colombia. To 1100 m in S Venezuela; c. 1000 m, rarely to 2200 m, in Colombia; mostly below 800 m, with small numbers as high as 1300 m, in Ecuador; up to c. 1000 m in Peru.
Food and Feeding. Insects, also small amounts of fruit. Of three stomachs examined, one contained only vegetable matter and two only animal matter, including spiders (Araneae), termite workers (Isoptera), grasshoppers (Caelifera), beetles (Coleoptera). Other items recorded included a lepidopteran, an orthopteran, and a mantis (Mantodea). Of 223 observations of feeding, only 12% involved fruit; fruit items noted in Panama included *Miconia* species, *Zanthoxylum*, *Xylopia* and *Lindackeria*. Trinidad data suggest larger proportion of fruit (29%) in diet. Pairs or families are normally core members of mixed-species flocks, foraging from lower midddle levels to subcanopy; pairs may travel and forage alternately with understorey or canopy mixed flocks. A very active, energetic species notable for its fondness for middle-storey forest vine tangles. Mostly hops or flits short distances in foliage and vines, and actively snatches insect prey from upper leaf surfaces by lunges, flutter-chases or short sallies. In Panama, almost half of 75 foraging records were between 9·5 m and 15 m up, and a further 35% were higher; 75% of foraging sites were tops of leaves, majority involving acrobatics such as lunges, leaps and sallies in outer foliage. Trinidad data suggest a lower range of foraging heights, mostly 3–15 m, and a larger proportion of fruit taken. In threat display to competitors, male puffs up shoulder feathers in bold display of white.
Breeding. Following details from Trinidad. Breeding recorded in Apr, Jun and Sept; nest a deep open cup of dry grass, lined with fine fibres, placed 1–1·5 m up in undergrowth; clutch 3 eggs, rich buff to pale cream, blotched reddish-brown. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Widespread and common to locally common. E of Andes found in many protected parks and reserves, including Voltzberg National Park (Suriname), Iwokrama Wilderness Reserve (Guyana), Canaima National Park (Venezuela), and Cahuinarí, Chiribiquete and Amacayacu National Parks (Colombia), also Cuyabeno Faunistic Reserve and Yasuni National Park (Ecuador) and Pacaya-Samiria National Reserve and Manu Biosphere Reserve (Peru); occurs also in numerous private reserves around eco-lodges, e.g. Napo Wildlife Centre, in Ecuador, and Explorama and Explornapo Lodges, near Iquitos, in Peru. Its range encompasses large areas of intact forest not formally protected, but at low risk of deforestation in immediate future, ensuring viability of this species at least in short term. Populations in Central America (primarily Caribbean slope) and W of Andes in Colombia and Ecuador also occur in numerous national parks and public and private reserves; as a result of widespread deforestation in unprotected areas within these regions, however, these populations have suffered local habitat contractions and range fragmentation and have almost entirely disappeared from some former areas. So long as parks and reserves are maintained, these W populations are considered unlikely to become at risk.

47. Tawny-crested Tanager

Tachyphonus delatrii

French: Tangara de Delattre **German**: Schwarzachseltangare **Spanish**: Tangara de Delattre

Taxonomy. *Tachyphonus Delatrii* Lafresnaye, 1847, Buenaventura, south-west Colombia.
Colour and size of coronal patch variable, but not in any seemingly systematic way, and naming of geographical races unwarranted. Monotypic.
Distribution. E Honduras S on Caribbean coast to Panama (sight record also in Veraguas, on Pacific slope of Panama), and from Colombia (N base of W & C Andes E to middle Magdalena Valley) S on Pacific coast to NW Ecuador (Esmeraldas and Pichincha), also Gorgona I, in Colombia.

Descriptive notes. 14 cm; 14–21 g. Noisy dark-plumaged tanager with fairly slender and sharply pointed bill, male with bright "Mohawk" crest. Male is mainly glossy black above and below, with prominent but close-cropped tawny to orange-yellow to dark yellow crown patch (colour variation possibly related to age); underwing-coverts white, small (usually concealed) white patch at bend of wing; iris reddish-brown; bill black, basal half of lower mandible pale greenish-grey to bluish-grey; legs blackish. Female is very dark overall, has head greyish-brown, upperparts uniformly dull dark olive-brown, slightly paler below, especially on throat; wing-coverts, flight-feathers and tail dusky. Subadult male is much like female, but darker, and may show evidence of tawny-yellow crest even before black feathers appear. Voice. Calls include metallic "tchit" or "zick", a higher "tsip" or "tchewp", and a distinctive high, sibilant "zeeet" or "pseeet" with scratchy quality. Song unrecorded.
Habitat. Humid and wet forest interior, but most numerous in overgrown forest borders, tall second growth and shrubby cut-over areas. Lowlands to c. 800 m in all areas; occasionally to 1200 m in Costa Rica and 1500 m in Colombia.
Food and Feeding. Few details of diet. Stomach of one bird from Panama contained bits of elytra of a beetle (Coleoptera) (4% of contents) and fragments of 25 ants (Formicidae) of two species (96%). When foraging, almost always found in large, noisy, fast-moving flocks of 6–12 (occasionally up to 20) individuals in lowlands, generally in smaller groups of 3–4 birds at higher elevations; in monospecific flocks or sometimes joined by a few other species, or temporarily joins large mixed-species flocks. Troops tend to sweep rapidly through an area, creating considerable commotion, chattering constantly as they hop, peck at prey, lunge, flutter in front of leaves, and occasionally hang downward in acrobatic manner, mostly to search foliage. Seldom remain in view for more than a few moments.
Breeding. Probably breeds in Mar–Jun in Costa Rica; in NW Colombia 18 breeding-condition birds between Feb and May, one in Mar (in Chocó) and one in Feb (in W Valle). One Apr nest in Costa Rica was a deep, bulky cup, one side higher and forming a partial roof, constructed mostly from green moss, with lining of fine material, placed 1·5 m up in dense shrub beside forest trail; contained 2 eggs, pale green with a wreath of fine black blotches and scrawls. No further information available.
Movements. Mainly resident. Some local movements suggested: in Colombia, nearly absent in middle Magdalena Valley in Mar, whereas was common there during May.
Status and Conservation. Not globally threatened. Locally fairly common. One old report from Bolivar–Chimborazo border, in C Ecuador, well S of current range. Occurs in many parks and reserves, including La Selva Biological Reserve and Braulio Carrillo National Park (Costa Rica), Soberanía, Chagres and Darién National Parks (Panama), the Comarca Kuna Yala Indigenous Reserve (also Panama), and Los Katíos National Park and Tambito Natural Reserve (Colombia); probably also in other protected areas in SW Colombia and W Ecuador. Found also in many areas of unprotected forest and second growth and, while range contraction and fragmentation has occurred in many parts, the species is well adapted to utilize second-growth woodland, and its short-term viability seems assured. It may be most at risk in parts of W Ecuador, where virtually all former lowland forest habitat has now been removed and converted to settlement and agriculture.

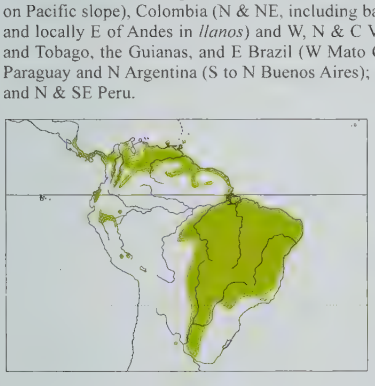
48. Ruby-crowned Tanager

Tachyphonus coronatus

French: Tangara couronné **German**: Krontangare **Spanish**: Tangara Coronada

Taxonomy. *A.*[*gelaius*] *Coronatus* Vieillot, 1822, Páxaros, Paraguay.
Recent molecular-genetic data indicate that this species and *T. rufus* are sister-species, and that *T. phoenicius* is sister to both of these. Monotypic.
Distribution. SE Brazil (N Mato Grosso do Sul E to extreme SE Bahia, S to C Rio Grande do Sul), E Paraguay and NE Argentina (Misiones and N Corrientes).



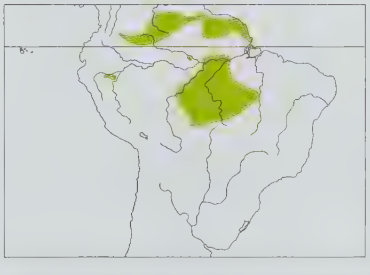
Descriptive notes. 16 cm; 26–33 g. Male is mainly glossy blue-black, with narrow (usually concealed) red patch in centre of rear crown; underwing-coverts white (usually conspicuous in flight), and may show small white patch on scapulars (usually hidden); iris dark brown; bill black, lower mandible bluish-grey with black on tip often extending over distal half; legs dark grey. Female has head greyish, otherwise mostly rufous-brown above, rump and tail more rufescent, dull yellowish-buff below, throat paler, breast with faintly indicated dusky streaking. Subadult male has mixture of brown and black in plumage. Voice. Song varies individually, typically rich melodious phrases, e.g. "whit-it chéw, chew-chew", a whistled "whildit, dit" or "whildit deo", or "whilt cheo", "chit chur whee-o, whit dittle chit...", and so on; in Brazil has been described as a monotonous, staccato, leisurely series of phrases each of 3–4 syllable, e.g. "chep-chep-cho, tsewléé-tsuk, tsewléé-tsuk". Calls, by both sexes, include emphatic "chet" and "twick".
Habitat. Found mostly in semi-open, lightly wooded or shrubby areas, including open woodland, shrubby forest borders, uncultivated fields (*capoeiras*), orchards, plantations, parks, gardens and settled areas with woodlots and patches of thick vegetation; generally not in clearings and open areas. Lowlands to c. 1300 m.
Food and Feeding. Arthropods, also wide variety of fruit, and seeds. Among fruits recorded in diet are melastomes (including *Leandra*), *Cecropia*, palms, bananas, oranges, and bromeliad fruits (*Neoregelia* and *Nidulariam*). Of 22 stomachs examined, one contained only vegetable matter and eight only animal matter, and 13 contained both; contents included orthopterans, beetles (Coleoptera) including weevils (Curculionidae) and leaf beetles (Chrysomelidae), ants (Formicidae) and other hymenopterans, fruits, also seeds including those of figs (*Ficus*). Mainly singly and in pairs; seasonally in small family parties seen, more rarely larger groups, and usually not with mixed-species flocks. Forages at middle heights or higher in open woodland, lower along forest borders. Restless, often constantly flicking wings and, when excited, showing red crest. Peers in foliage for arthropod prey.
Breeding. In Brazil, breeding reported in Oct–Jan in Rio de Janeiro and São Paulo. Cup-nest of grass, lined with rootlets, placed less than 2 m up in thicket, coffee bush or other dense vegetation, sometimes beside stream. Clutch 2–3 eggs, pink to white, blotched and smeared with shades of red and brown, more at large end and sometimes with black scrawls; incubation in captivity 13 days; no information on nestling period.
Movements. May be partially migratory in Rio de Janeiro, in SE Brazil.
Status and Conservation. Not globally threatened. Locally common throughout range. Occurs in numerous protected areas in both Argentina and S Brazil, and adapts well to a variety of edge, second-growth and disturbed habitats. Not at any apparent risk.
Bibliography. Belton (1985), Burns & Racicot (2009), Davis (1946), Descourtilz (1852), Diamond & Lovejoy (1985), Erickson & Mumford (1976), Euler (1867, 1900), Holt (1928), Ihering (1900), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Mitchell (1957), Moojen *et al.* (1941), Narosky & Yzurieta (1987), Nehrkorn (1899), Norgaard-Olesen (1974), Ogilvie-Grant (1912), Parker & Goerck (1997), de la Peña & Rumboll (1998), Ridgely & Tudor (1989, 2009), Santos (1948), Schubart *et al.* (1965), Short (1971), Sick (1985, 1993), Snethlage & Schreiner (1929), Souza (2002), Willis (1979).

49. White-lined Tanager

Tachyphonus rufus

French: Tangara à galons blancs **German**: Schwarztangare **Spanish**: Tangara Negra

Taxonomy. *Tanagra rufa* Boddaert, 1783, Cayenne, French Guiana.
Recent molecular-genetic data indicate that this species and *T. coronatus* are sister-species, and that *T. phoenicius* is sister to both of these. Despite extensive range, no regular geographical variation identified. Monotypic.
Distribution. SE Nicaragua, Costa Rica (Caribbean coast), SW Panama (Caribbean slope and locally on Pacific slope), Colombia (N & NE, including base of Santa Marta Mts, most of Andean region, and locally E of Andes in *llanos*) and W, N & C Venezuela (including Margarita I) E to Trinidad and Tobago, the Guianas, and E Brazil (W Mato Grosso S to N Paraná) S to extreme E Bolivia, Paraguay and N Argentina (S to N Buenos Aires); also isolated populations in NW & SE Ecuador and N & SE Peru.



Descriptive notes. 17 cm; 25·7–42·5 g. Male is entirely glossy blue-black, except for white underwing-coverts (flash of white when bird in flight); small amount of white at bend of wing and occasionally on marginal coverts (almost always hidden when bird at rest); iris dark brown; bill blackish, lower mandible bluish-grey with black on tip often extending over distal half; legs horn-grey to dark grey. Female is uniformly rufous, slightly paler below; flight-feathers dusky, edged and tinged rufous. Immature is like female; subadult male similar, but with variable amount of black mottling and patchiness (which can appear almost anywhere in plumage). Voice. Infrequently heard song in Venezuela, sometimes given in flight, a bouncy, chattery "chuéé, chuit, chuit-chuit-chuit" and so on, first syllable strongest; in Mérida (W Venezuela) a soft tentative "cheewank, wink, cheewank, wink, cheewank...", first note falling, second rising, in leisurely hypnotic cadence. In Trinidad described as a somewhat musical "chip-chiwer, chip-chur, chip-wheeeo, cheeru, chéép-chooi" or "chip-chip-wheer", repeated rapidly over and over. Dawn song of 2–4 phrases separated by pauses of 5–6 seconds. In Ecuador song described as a musical but repetitive "chip chirp weep chirp chip chirp weep...". Call a soft, rising "sweet".
Habitat. A non-forest species found in shrubby clearings, moist and humid forest borders, cultivated areas, plantations and gardens. Lowlands to c. 1800 m, occasionally slightly higher; humid foothill and montane areas in Venezuela and Colombia.
Food and Feeding. Of 22 stomachs examined, seven contained only vegetable matter and eleven only animal matter, and four contained both; contents included ants (Formicidae), beetles (Coleoptera), bugs (Hemiptera), flies (Diptera), spiders (Araneae), feather fragments, also fruit, berries and seeds; also reported as eating caterpillars, a moth (Lepidoptera) and a katydid (Tettigoniidae) in Venezuela. Observed to consume papayas (*Carica papaya*), guavas (*Psidium*) and other commercial and garden fruits. In Trinidad, 28 species of fruit recorded in diet, epiphytes accounting for 35%, *Miconia* for 20% and *Cecropia* for 14% of the total. Almost always in pairs, partners keeping close together and staying low in bushy clearings; often pop up into the open briefly before flying off, one following its mate in low flight across an opening. Usually independent of mixed-species flocks. Rather active, often flicking wings as it hops and peers in foliage, but forages mostly less than 6 m above ground, and often on ground; in all areas tends to stay out of sight when foraging. Of 238 records of feeding attempts in Trinidad, 60% involved fruit, 30% insect-seeking, and 10% were at flowers; small fruits usually mashed before being eating; flowers or flower parts picked or squeezed, presumably for nectar. Gleans and picks insects from leaves, makes short sallies to air, and regularly drops to ground for insects; of 74 observed instances of insect-catching, 51% were on the ground, 32% in foliage, 14% in aerial sallies, and 3% from branches. Has occasionally been noted at army-ant swarms and taking flying termites (Isoptera).
Breeding. Recorded in May in Panama, Feb, Apr, Jun and Oct in Venezuela (Mar–May in upper R Orinoco), Feb–Aug and Nov (mostly Apr–Jun) in Trinidad, Jan–Mar in Peru, and, in Brazil, Oct–Jan in Pará and Oct in Mato Grosso. Bulky cup-nest of leaves, tendrils and rootlets, placed 1·2–6 m above grund in shrub or tree, once reported in tall grass, and occasionally to 12 m up in tree or banana plant. Clutch 2–3 eggs (infrequently 1), white to light purplish with darker markings; incubation by female, period 14–15 days; chicks fed by both adults, no information on duration of nestling period. Parasitized by Shiny Cowbird (*Molothrus bonariensis*).
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Common and reasonably widespread in suitable habitat in Venezuela and Colombia; scarce and local, but perhaps increasing, in Ecuador; widely distributed across E Brazil. Occurs in numerous protected areas throughout its ample range, and is well adapted for using a variety of edge, second-growth and disturbed habitats. Has profited from partial deforestation and settlement, and has expanded into areas that were formerly unsuitable. In Argentina, was rarely reported around Buenos Aires prior to c. 1999, but since then has gradually increased and is, at least for the moment, well established, with breeding confirmed. Uncertain if escaped cagebirds were the source of Buenos Aires population, although the species is not commonly kept in captivity.
Bibliography. Allen (1891), Belcher & Smooker (1937), Burns & Racicot (2009), Chapman (1926), Cherrie (1916), Collins & Araya (1998), Davis (1972), Diamond & Lovejoy (1985), Donegan & Dávalos (1999), Euler (1900), Ffrench (1991), Forbes (1881), Friedmann & Smith (1950), Fry (1970), Garrigues & Dean (2007), Gilliard (1959), Ginés *et al.* (1951), Hallinan (1924), Hartman (1955), Hartman & Brownell (1961), Hilty (1997, 2003), Hilty & Brown (1986), Haverschmidt (1948, 1968), Haverschmidt & Mees (1994), Isler & Isler (1999), Jahn *et al.* (2002), Layard (1873), Lysinger *et al.* (2005), Miller (1963), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Narosky & Di Giacomo (1993), Novaes (1973), Novaes & Pimentel (1973), Ogilvie-Grant (1912), Olivares (1963), Peixoto Velho (1932), de la Peña & Rumboll (1998), Phelps & Phelps (1963), Pinto (1944a), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schäfer & Phelps (1954), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sclater & Salvin (1879), Sick (1985, 1993), Slud (1964), Snethlage (1935a), Snethlage & Schreiner (1929), Snow, B.K. & Snow (1971), Snow, D.W. & Snow (1964), Snyder (1966), Souza (2002), Stiles & Skutch (1989), Stone (1918), Strauch (1977), Taczanowski (1884), Thomas (1982), Todd & Carriker (1922), Tostain *et al.* (1992), Walker (2001), Wetmore (1926), Zimmer (1945).

50. Red-shouldered Tanager

Tachyphonus phoenicius

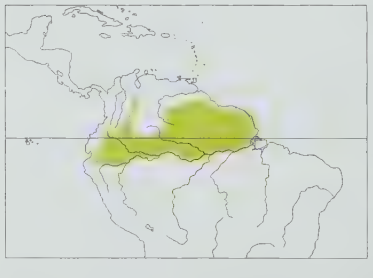
French: Tangara à galons rouges **German**: Rotschultertangare **Spanish**: Tangara de Galones

Taxonomy. *Tachyphonus phoenicius* Swainson, 1838, Bioko; error = possibly east Peru.
Recent molecular-genetic data indicate that *T. coronatus* and *T. rufus* are sister-species, and that present species is sister to both of them. Monotypic.
Distribution. Three geographically separated populations. E Colombia E locally to S Venezuela, the Guianas and N Brazil (N Roraima and N Amapá); NE Peru (W Loreto S of R Marañón S to San Martín and N R Ucayali); Brazil mostly S of R Amazon (locally on N bank) between R Madeira and R Tapajós, S to NW Mato Grosso and, perhaps discontinuously, to Bolivia (E Beni).

Descriptive notes. 15 cm; 17–25 g. Male is almost entirely glossy blue-black, with white underwing-coverts; small amount of red mixed with white at bend of wing and on marginal wing-coverts (often visible in flight, but rarely so when at rest); iris dark brown; upper mandible black, lower mandible pale blue-grey with small black tip; legs horn-grey. Female has crown and side of head dark brownish-grey, feathers of crown with dark centres and paler edges (giving slightly scalloped appearance), slightly darker mask extending through lores, ocular area and to below eyes, this contrasting sharply with whitish throat; upperparts, including uppertail-coverts, tail, and upperwing and its coverts, dark brownish-grey; white of throat merges with grey-tinged dirty white on breast and sides; lower underparts dingy creamy white.

On following pages: 51. Fulvous Shrike-tanager (*Lanio fulvus*); 52. White-winged Shrike-tanager (*Lanio versicolor*); 53. Black-throated Shrike-tanager (*Lanio aurantius*); 54. White-throated Shrike-tanager (*Lanio leucothorax*).

Juvenile is like female, but streaked dusky below. Voice. Song, in SE Venezuela (1400 m), a musical but rather repetitive and medium-pitched "cheurt- che'e'e't-che'e'e't, cheurt- che'e'e't-che'e'e't-che'e'e't,...", delivered at leisurely pace and in rather sing-song fashion; may continue for up to several minutes with scarcely a break. In general sings relatively little; song possibly seasonal. Call notes include high, thin, insignificant "chup", "cheup" and "tsit".
Habitat. Occurs predominantly in white-sand or other sandy-soil zones with savanna, scattered high bushes, thickets, patches of light woodland and scrubby vegetation around rocky outcrops; also scrubby savanna openings in sandy-soil forest regions. In C Brazil mainly lowlands to c. 400 m; locally to 1350 m in Peru; to 2000 m in tepuis of S Venezuela.
Food and Feeding. Arthropods and small fruits. Of nine stomachs examined, two contained only vegetable matter and seven only animal matter; contents included ants (Formicidae), beetles (Coleoptera) including weevils (Curculionidae), bugs (Hemiptera), and seeds. Spiders (Araneae) found in other stomachs. Single individuals, pairs and families are often restless and nervous-acting as they wander alone in bushy savanna, or less often with small mixed-species parties in scrubby woodland or borders. Can be rather wary and difficult to approach. Hops and flits mostly 1–6 m up in dense, leathery foliage of savanna bushes. Reported as regular in upper foliage of palms and woodland patches in N Peru.
Breeding. Breeding reported in Feb and Mar in Suriname. Grassy cup-nest built on ground and concealed in grass or near bushes in Suriname. Clutch 1–2 eggs, greyish, spotted and entirely blotched chocolate-brown at larger end. No other information.
Movements. Probably resident; no local or migratory movements reported. Breeders in N Argentina possibly migratory.
Status and Conservation. Not globally threatened. Uncommon to fairly common, but often quite local; generally found at low density. Each of three geographically isolated populations occurs in a number of protected areas, e.g. Kaieteur National Park (Guyana) and Canaima National Park (Venezuela). Isolated sandy-soil population in NE Peru occurs in Pacaya-Samiria National Park, but much of its range also is in nearby unprotected areas, which are subject to deforestation and human settlement. Large population S of R Amazon in Brazil is, as elsewhere, local in sandy-soil regions. This species is adapted to scrubby second growth and semi-open habitats, and is capable of persisting in degraded areas.
Bibliography. Burns & Racicot (2009), Friedmann & Smith (1950), Gilliard (1941), Haverschmidt (1952, 1956, 1968, 1975), Haverschmidt & Mees (1994), Hellmayr (1910), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Novaes (1978, 1980), Olivares (1959), Phelps & Phelps (1950, 1963), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sick (1985, 1993), Snethlage (1914), Snyder (1966), Souza (2002), Tobias (2007), Tostain *et al.* (1992), Zimmer (1945).



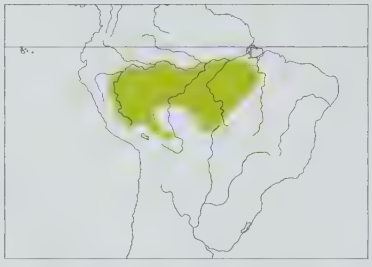
Genus *LANIO* Vieillot, 1816

51. Fulvous Shrike-tanager

Lanio fulvus

French: Tangara mordoré **German**: Braunbrust-Würgertangare **Spanish**: Tangara Fulva

Taxonomy. *Tangara fulva* Boddaert, 1783, Cayenne, French Guiana.
Genetically most closely related to the two Middle American species *L. aurantius* and *L. leucothorax*; replaced S of R Amazon by *L. versicolor*. Original spelling has often been cited as "*sulva*", but this stems from typographical error in a later copy; original spelling is "*fulva*". Two subspecies recognized.
Subspecies and Distribution.
L. f. peruvianus Carriker, 1934 – E base of Andes in W Venezuela (Táchira) S to S & SE Colombia, E Ecuador and NE Peru (S to N bank of R Marañón and R Amazon in San Martín and Loreto).
L. f. fulvus (Boddaert, 1783) – SE Venezuela (S of R Orinoco), the Guianas, and N Brazil (N of R Amazon, E to Amapá).



Descriptive notes. 15–17 cm; 19–30 g. Slender tanager with strong, sharply hooked bill with well-developed "tooth" on cutting edge of upper mandible. Male nominate race has entire head and throat black (like a hood), upperwing and tail black, upperparts apricot-yellow, brightest on nape and gradually shading to rufescent brown on uppertail-coverts; large patch on breast tawny-rufous, remaining underparts yellowish-ochre, turning cinnamon on undertail-coverts; iris dark brown; bill black; legs blackish. Female somewhat variable, has greyish-brown crown, becoming warm brown on upperparts, richest on rump and uppertail-coverts; wing feathers dusky, washed warm brown on outer edges (warm brown predominates on folded wing), folded tail appears ochraceous to rufescent brown; side of head pale dull reddish-brown, becoming paler, more grey-buff on throat, changing to ochraceous olive on breast and orangish-buff on belly and undertail-coverts (sometimes strongly tinged greenish-yellow below); legs brownish-grey to pinkish-grey. Immature male is like female, but with blackish patches on head, and lower underparts slightly paler yellowish. Race *peruvianus* male has body plumage overall darker, more fulvous, than nominate, only nape bright yellow. Voice. Noisy. Frequently utters very loud, sharp, descending "tseuuu!" (may help those in mixed-species flock to keep track of flock location in canopy). Alarm call, also false alarm call, the same descending note, but repeated rapidly several times (twice normal rate) and with strong harmonic structure; non-alarm notes delivered at half the rate of alarms and descend through twice frequency range. Song, at dawn, a high forced "tzee-a, tzee-a, tzee-a".
Habitat. Fairly common to common in tall, humid *terra firme* and *várzea* forest, and at forest borders in lowlands and lower slopes. Lowlands to c. 1350 m; in Ecuador regularly to c. 1100 m, once to 1750 m.
Food and Feeding. Of four stomachs examined, two contained only vegetable matter and two contained both vegetable and animal matter; contents insects and seeds. Other stomachs contained click beetles (Elateridae), weevils (Curculionidae), and bugs (Hemiptera) including homopterans. Acts as sentinel in middle-level to canopy mixed-species flocks, in which almost always at the centre of flock activity. Single individuals or separated pairs sit rather upright on relatively open middle-level or subcanopy perches and alertly watch activities of other birds, mostly above them, waiting for their varied activities to dislodge or flush prey, which present species then chases down in rapid sallies like those of tyrant-flycatchers (Tyrannidae). Also occasionally sallies to foliage or branches. Because of its open-perch position and visibility, this species is almost always the first member of flock to sound alarm at approaching danger.
Breeding. Few data. Breeds in Oct in French Guiana. One nest reported as built in a palm, although this may not be a typical nest-site. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Relatively widespread and fairly common. Range incorporates a number of protected areas, including Canaima National Park (Venezuela), Iwokrama National Park (Guyana), Voltzberg Nature Park (Suriname), Tinigua, La Paya, Chiribiquete, Amacayacu and Cahuinarí National Parks and others (Colombia), Cuyabeno Faunistic Reserve and Yasuní National Park (Ecuador), and Pacaya-Samiria National Reserve (Peru). Also occurs widely in unprotected lowland Amazonian and Guianan forests. Not likely to be at risk globally in immediate future, although foothill populations at E base of Andes in Venezuela and Colombia have undoubtedly declined significantly as a result of extensive and uncontrolled deforestation, and these populations are now severely fragmented.

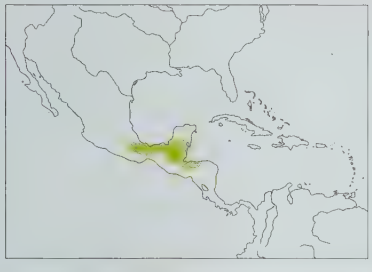
52. White-winged Shrike-tanager

Lanio versicolor

French: Tangara versicolore **German**: Gelbstirn-Würgertangare **Spanish**: Tangara Aliblanca

Taxonomy. *T.[achyphonus] versicolor* d'Orbigny and Lafresnaye, 1837, Yuracares, Bolivia.
Despite close approach geographically by *L. fulvus*, which replaces this species N of R Amazon, the two are differentiated genetically by a remarkably large amount (7/0%). Two subspecies recognized.
Subspecies and Distribution.
L. v. versicolor (d'Orbigny & Lafresnaye, 1837) – S of R Amazon in E Peru (S of R Marañón), W Brazil (E to R Tapajós) and N Bolivia.
L. v. parvus Berlepsch, 1912 – EC Brazil S of Amazon (from R Tapajós E to lower R Tocantins, S to Mato Grosso) and extreme NE Bolivia.



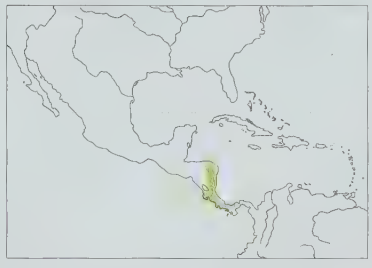
Descriptive notes. 13–15 cm; 13–20 g. Slender tanager with strong, sharply hooked bill, upper mandible with well-developed "tooth" on cutting edge. Male nominate race has head black, with dark olive-yellow forecrown (hard to see in field) and dark olive throat; most of upperwing-coverts white, forming large conspicuous patch, otherwise wing and tail black; upperparts, including uppertail-coverts, ochraceous to cinnamon, brighter and more yellow on rump; breast, belly and entire lower underparts deep yellow, tinged brownish-ochre on chest; iris dark brown; bill black; legs blackish. Female is nearly uniformly coloured above, mainly warm olive-brown, wing browner and rump and tail tinged rufescent brown; throat and breast ochraceous brown to ochraceous cinnamon, more yellow on middle of lower underparts; bill dusky horn-grey, legs greyish-brown. Juvenile mainly dingy brown; immature female slightly duller than adult female; immature male like adult female, older birds acquiring black mottling on head, with flight-feathers and tail becoming dusky. Race *parvus* male is probably indistinguishable from nominate, female differs from nominate in having throat, breast and flanks more olive to olive-brown and undertail-coverts paler. Voice. Commonest call a loud, forceful, often repeated "twéééu!", explosive and descending, given as contact call (to indicate whereabouts of flock to various flock-members); uttered in rapid series in alarm. Dawn song a fairly high, whistled "tee-uu, tee-uu, tee-uu, tee-uu", this occasionally given also as day song but usually then shorter; a brief "twée-chu-twít-tu-weét" is apparently also a song.
Habitat. Upper levels of humid *terra firme*, transitional and *várzea* forest, infrequently also at forest borders, and occasionally wanders to large shady trees in clearings adjacent to tall forest. Generally not in river-edge second-growth vegetation. Lowlands and foothills to c. 1200 m; most records below c. 900 m.
Food and Feeding. Of four stomachs examined, one contained only vegetable matter and three contained only animal matter; contents were insects and fruit pulp. Occurs mainly in pairs or families that are, in many respects, pivotal to cohesion of canopy mixed-species flocks. Individuals sit very upright, usually on fairly open vine or horizontal branch in subcanopy or somewhat below other members of canopy mixed flock, from where they call continually, watch carefully and sally rapidly to bark or leaf surfaces or to air for prey, most of which has been dislodged or disturbed by other flock-members; flight fast, and individuals capable of aerobatics as they pursue mostly insect prey; may deliberately utter false alarm calls to warn away other birds pursuing same flying prey (false alarms infrequent, but increase when adults feeding young).
Breeding. Nest-building and one nest with nestlings in Nov in SE Peru. Nest was cup-shaped, made from plant fibres woven in concentric rings, with base of twigs and dead leaves, outer diameter 8 cm and height c. 8 cm, inner depth c. 2 cm; placed 0·9 m above ground at base of leaves of a trunk-epiphyte fern (*Lomariopsis japurensis*). Nest held two chicks c. 5 days old and nearly naked (only grey down feathers on capital, spinal and ventral tracks); both adults observed to carry food, including a caterpillar and unidentified items, to nest. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Widespread and fairly common to common across almost entire Amazonian Basin S of Amazon. Occurs in numerous protected areas and parks, including Manu Biosphere Reserve and Tambopata-Candamo Reserve Zone (Peru), Madidi National Park (Bolivia), and Serra do Divisor, Jaú and Amazonica National Parks (Brazil). Extensive intact habitat also exists outside protected areas, and this species seems at little risk.
Bibliography. Burns (1997a), Burns & Racicot (2009), Burns *et al.* (2002, 2003), Isler & Isler (1999), Marantz & Zimmer (2006), Mee *et al.* (2002), Munn (1984, 1985), Munn & Terborgh (1979), Naumburg (1930), Oren & Parker (1997), Ridgely & Tudor (1989, 2009), Schulenberg (2000c), Schulenberg *et al.* (2007), Snethlage (1914), Souza (2002), Tello (1999), Terborgh & Weske (1969), Weske (1972), Zimmer (1945).

53. Black-throated Shrike-tanager

Lanio aurantius

French: Tangara à gorge noire **Spanish**: Tangara Gorjinegra
German: Schwarzkehl-Würgertangare
Other common names: Great Shrike-tanager

Taxonomy. *Lanio Aurantius* Lafresnaye, 1846, Colombia; error = Guatemala.
May form a superspecies with *L. leucothorax*, and in the past often treated as conspecific. Recent molecular data indicate that the divergence between the two is only 0·9%; their geographical distributions are discrete (although approach each other in Honduras), and the two differ mainly in some plumage characteristics; they perhaps represent a recent speciation event combined with rapid plumage divergence. Monotypic.
Distribution. Caribbean slope of SE Mexico (from C Veracruz) E to lower Yucatán Peninsula, S to N & C Guatemala, Belize and Honduras (E to vicinity of La Ceiba).



Descriptive notes. 19–20 cm. Slender tanager with fairly long tail and hooked bill, upper mandible with well-developed "tooth" on cutting edge. Male has head, nape, throat, upperwing and tail black, rest of plumage mainly bright yellow, lesser wing-coverts tipped white (white usually concealed by scapulars), small brownish-ochre wash across chest; iris dark brown; bill black; legs blackish. Female has head grey, with olive tinge on crown, upperparts tawny-brown, strong rufescent tinge on rump and tail; throat grey, paler than head, breast and belly yellow, olive wash on chest, sides and flanks, with ochre undertail-coverts; bill blackish. Immature male is much like female, but brighter yellow below, and brighter, more cinnamon-brown, above; acquires adult plumage in c. 1 year. Voice. Rather noisy, with loud contact and alarm calls that arouse other foraging birds. Common call a sharp, rhythmic "chee'choo", often repeated persistently, and may be preceded by other notes, e.g. "shih, shih, chee'choo, chee'choo..."; also gives loud descending "teeuw" and soft warble mixed with "teeuw" notes. Song may be a descending "twt, dit, doo, tchew, tchew", last notes loud and slurred; apparent song also described as "stcheee" followed by c. 4 rich "chee" notes, each falling slightly in scale, and ending with several more level "chee" notes.
Habitat. Interior of tall humid forest, less frequently along forest borders. Sea-level to 1200 m; most records below 750 m.
Food and Feeding. Few data on diet; insects recorded. Occurs in pairs in middle and upper levels of tall forest, or occasionally lower, typically in rather open portions of forest, and almost always with mixed-species flocks. Perches alert and upright, often without moving for periods of time, and seems to behave as sentinel for other members of mixed flock; utters loud sharp alarm notes at slightest provocation. Sallies for fleeing prey, which it often captures in air at the end of fast aerobatic chases. Behaviour similar to that of *L. versicolor*.
Breeding. No information.
Movements. Resident. Possible wandering in winter reported.
Status and Conservation. Not globally threatened. Locally fairly common. This species occurs in a number of protected areas, including Tikal National Park (Guatemala) and Cockscomb Wildlife Sanctuary (Belize). Deforestation throughout its range in S Mexico is extensive and has resulted in dramatic range contraction and fragmentation. Large amounts of unprotected habitat remain, however, in N Guatemala, Belize and Honduras. Despite local population declines, this species' long-term viability should be assured so long as protected areas in its range are maintained; the future of such unprotected intact habitat is, however, uncertain.
Bibliography. Blake (1953), Burns & Racicot (2009), Davis (1972), Edwards & Tashian (1959), Eisenmann (1955), Griscom (1932), Howell & Webb (1995), Isler & Isler (1999), Land (1970), Monroe (1968), Paynter (1955), Peterson & Chalif (1973), Russell (1964), Salvin & Godman (1883), Smithe (1966), Tashian (1952), Wetmore (1943), Willis (1960a).

54. White-throated Shrike-tanager

Lanio leucothorax

French: Tangara à gorge blanche **Spanish**: Tangara Gorjiblanca
German: Weißkehl-Würgertangare

Taxonomy. *Lanio leucothorax* Salvin, 1865, Tucurrique, Costa Rica.
May form a superspecies with *L. aurantius*, and in the past often treated as conspecific. Recent molecular data indicate that the divergence between the two is only 0·9%; their geographical distributions are discrete (although approach each other in Honduras), and the two differ mainly in some plumage characteristics; they perhaps represent a recent speciation event combined with rapid plumage divergence. Four subspecies recognized.
Subspecies and Distribution.
L. l. leucothorax Salvin, 1865 – Caribbean slope from Honduras (Olancho) S to E Costa Rica (S to Limón, also locally on W slope in Guanacaste).
L. l. reversus Bangs & Griscom, 1932 – Las Agujas (NW Puntarenas), in W Costa Rica.
L. l. ictus Kennard & J. L. Peters, 1927 – lowlands and foothills around Almirante Bay (NW Panama).
L. l. melanopygius Salvin & Godman, 1883 – Pacific slope from W Costa Rica (Puntarenas S of entrance to Gulf of Nicoya) S to W Panama (Chiriquí, both slopes in Veraguas, and foothills on Caribbean slope of W Coclé).

Descriptive notes. 20 cm; 30–45 g. Slender tanager with fairly long tail and strong bill sharply hooked at tip, upper mandible with well-developed "tooth" on cutting edge. Male nominate race has crown, nape and side of head black, upperparts to rump rich yellow, upperwing, uppertail-coverts and tail black; lesser upperwing-coverts white, forming narrow white bar (often concealed); chin black, throat white, becoming buff-tinged on chest, rest of underparts, including belly and undertail-coverts, bright yellow, thigh black, underwing-coverts white; iris dark brown; bill black; legs blackish. Female is much duller than male, head greyish-brown, dusky tinge on ear-coverts, upperparts reddish-brown, upperwing and tail dusky with feathers broadly edged brown, throat and chest buffy brown, tinged with grey (except on centre of throat), and shading to olive on breast and golden-yellow on belly; sides, flanks and undertail-coverts tinged cinnamon; bill dusky, legs possibly less blackish than male's. Immature is like female, but more rufescent, face russet with dusky scaling, upperparts dull chestnut-rufous, wing-coverts and flight-feathers brighter rufous, throat ochraceous buff, becoming bright ochraceous on chest and sides and buff-yellow on belly, with flanks and undertail-coverts pale rufous, bill greyish. Race *melanopygius* male differs from nominate in having most of upperparts (except for mantle) and lower belly and undertail-coverts black, female has throat paler, brownish-grey; *ictus* is similar to previous, but male has feathers of rump broadly tipped yellow, female throat intermediate between previous and nominate; *reversus* is much like *melanopygius*, but male has only rump (not back) black. Voice. Variety of sharp, sometimes scratchy chips and chatters. Commonest vocalization when with foraging flocks a loud, forceful whistle, "chéééw", sometimes several in succession, "chéééw, chéééw, churr-churr..." etc. Song a deliberate and rather low-pitched series of melodic notes followed by some higher whistles; song may be repeated over and over rapidly, or slowly.
Habitat. Interior of humid and wet lowland and foothill forest; throughout range occurs mainly in hill terrain and adjacent humid and wet foothills. Lowlands to c. 900 m in SE Costa Rica; mainly foothills on Caribbean slope of Panama.
Food and Feeding. Arthropods; fruit occasionally eaten. Of four stomachs examined, two contained only animal matter and two contained both animal and vegetable matter. Stomach contents included orthopterans, including cockroaches (Blattaria) and katydids (Tettigoniidae), homopteran bugs, beetles (Coleoptera) including weevils (Curculionidae), butterflies (Lepidoptera), and fruit. Travels in pairs or in families of three or four individuals that associate with mixed-species flocks at middle level to canopy; most typically encountered at subcanopy heights. Noisy, active, and quick to sound loud alarm notes at approach of danger. Perches erect on open branches or vines, often a little below other foraging species in mixed flocks, and occasionally down to eye level; watches alertly, often with rapid head movements, then sallies rapidly and aerobatically for insects or potential prey items dislodged by other flock-members. Prey often captured in air in large sweeping sallies. Large prey may be beaten against branches before being swallowed. Behaviour of this species is much like that of congeners.
Breeding. Recorded in May. One nest in Costa Rica was in low bush by stream inside forest; contained 2 eggs, white with bold chocolate-brown and greyish spots, more at larger end. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common throughout much of range. Occurs in a number of protected areas, among them Indo-Maíz Biological Reserve (Nicaragua), La Selva Biological Reserve and Braulio Carrillo, Carara, Corcovado and Chirripó/La Amistad National Parks (Costa Rica) and La Amistad National Park (W Panama). Unprotected intact habitat within the species' range is extensive in Nicaragua. On the other hand, deforestation nearly complete in unprotected portions of range in Costa Rica and Panama (e.g. in W Panama mostly extirpated in Chiriquí except on Burica Peninsula), and it now survives largely within confines of protected areas. Despite extensive contraction of its former range and habitat fragmentation, this species' long-term survival seems secure so long as protected areas within its range are maintained.

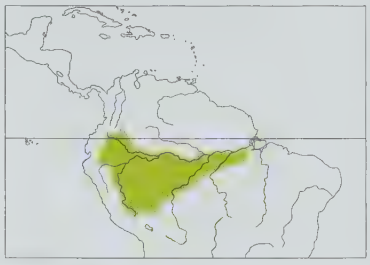
Genus *RAMPHOCELUS* Desmarest, 1805

55. Crimson-collared Tanager

Ramphocelus sanguinolentus

French: Tangara ceinturé **German**: Flammentangare **Spanish**: Tangara Acollarada

Taxonomy. *Tanagra* (*Tachyphonus*) *sanguinolentus* Lesson, 1831, Mexico.
In the past, was sometimes placed in a monotypic genus, *Phlogothraupis*. Bears close resemblance to others of present genus, and recent molecular-genetic studies support retention in latter. Two subspecies recognized.
Subspecies and Distribution.
R. s. sanguinolentus (Lesson, 1831) – SE Mexico (from Veracruz, N Oaxaca, Tabasco and Quintana Roo) S through Belize to Honduras.
R. s. apricus (Bangs, 1908) – Caribbean slope of E Honduras S to NW & C Panama, locally on Pacific slope in N Costa Rica.



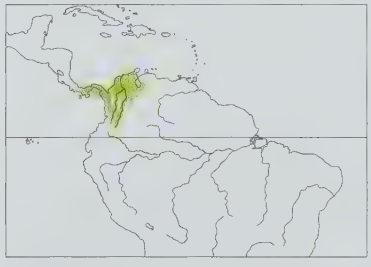
Descriptive notes. 17 cm; 35–48 g. Distinctive, with fairly long tail and heavy conical bill. Has forecrown, face and throat black, crown, nape, side of neck and breast glossy crimson; uppertail-coverts and undertail-coverts also glistening crimson, rest of body, including wing, tail and mid-breast to belly, deep black; iris reddish-brown; bill mostly whitish-blue-grey; legs dark horn-grey. Sexes essentially alike; some females slightly duller, but most indistinguishable from male. Immature has red areas of adult plumage replaced by dull rufous to brick-red with dusky feather bases (imparting mottled appearance), black areas dull brownish-black, bill duller, tomia greyish-horn. Voice. Song a leisurely sequence of rising and falling whistled notes separated by pauses, "tueee-teew, chu-che-wee chew, tewee". Overall not so vocal as some others of genus. Has variety of thin, metallic calls, including "tsewee" and "weet weee", and a grating "chuck".
Habitat. Thickets and bushes along humid-forest borders, adjacent pastures with trees, bushy second growth of various stages, especially rank vegetation along streams and in old plantations. Lowlands up to c. 1200 m.
Food and Feeding. Insects; also many fruits, including melastomes and figs (*Ficus*). Lives in pairs throughout year, also in family groups for short period after nesting season; occasionally accompanies mixed-species flocks containing other tanagers, and may join other species briefly at fruiting trees. Forages mostly 2–10 m up in leafy foliage of tall shrubs and lower part of trees, in general somewhat higher than *R. passerinii* and *R. costaricensis*. Hops and peers in foliage.
Breeding. Breeding reported in May in Belize, Mar–May in Nicaragua and Apr–Jun in Costa Rica. Male sings from elevated perches; more territorial than *R. passerinii*. Rather compact nest of leaves and small vines, sometimes covered with green moss, placed 1–2·5 m above ground in thick foliage in bush or vine tangle. Clutch 3 eggs, pale blue, spotted with brownish-black and faintly marked with lavender, especially at larger end. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to locally common. Range encompasses a number of parks and reserves, including Palenque National Park, Cascadas de Agua Azúl, Selva del Ocote, Sian Ka'an and Calakmul Biosphere Reserves, and Punta Put and Teacuterminos Lagoon Reserves (all in Mexico), Crooked Tree Wildlife Sanctuary, Cockscomb Wildlife Sanctuary and privately operated Chan Chich Lodge and Nature Reserve (Belize), Capiro–Calentura National Park and Guaimoreto Lagoon Wildlife Refuge (Honduras), Indo-Maíz Biological Reserve (Nicaragua), and La Selva Biological Reserve and Braulio Carrillo National Park (Costa Rica). Range also encompasses much suitable habitat that is not formally protected. Utilizes a variety of forest edge, bushy second-growth and disturbed habitats that buffer this species against potential habitat loss; indeed, it profits somewhat from the opening-up of heavily forested areas. Its range has contracted locally, especially in Chiapas, in Mexico, where areas have been almost completely deforested.
Bibliography. Anon. (1998), Berrett (1962), Binford (1989), Burns & Racicot (2009), Burns *et al.* (2002, 2003), Davis (1972), Garrigues & Dean (2007), Howell, S.N.G. & Webb (1995), Howell, T.R. (1957), Huber (1932), Isler & Isler (1999), Land (1970), Lowery & Dalquest (1951), Nehrkorn (1899), Peters (1929), Richmond (1893), Ridgely & Gwynne (1989), Russell (1964), Slud (1960, 1964), Smithe (1966), Stiles & Skutch (1989), Wetmore (1943), Wetmore *et al.* (1984).

56. Masked Crimson Tanager

Ramphocelus nigrogularis

French: Tangara masqué **German**: Maskentangare **Spanish**: Tangara Enmascarada
Other common names: Crimson Tanager

Taxonomy. *Tanagra nigrogularis* Spix, 1825, "ad flumen Solimoëns in sylvis pagi St. Pauli" = São Paulo de Olivença, River Solimões, Brazil.
Monotypic.
Distribution. E of Andes in Colombia (from Meta and Amazonas) S to E Ecuador and E Peru (S to Madre de Dios), and E, mostly S of R Amazon, to NC Brazil (to lower R Xingu, in E Pará).
Descriptive notes. 17 cm; 27–36 g. Distinctive red-and-black tanager with stout bill, lower mandible somewhat expanded at base. Has base of forehead, area around eye and upper throat black (forming mask), rest of head, nape, side of neck, and lower throat and most of underparts glistening red; back, rump and shortest uppertail-coverts glistening red, rest of upperparts, including entire wing and tail, jet-black; large black patch on centre of lower breast and belly; thigh black, and variable amount of black mixed with red on rear flanks and undertail-coverts; iris reddish-brown; upper mandible is black, lower mandible gleaming white with black tip; legs dark horn-grey. Sexes similar, female sometimes very slightly duller than male. Immature has plumage pattern similar to that of adult, but is much duller, dull brick-red and dusky. Voice. Dawn song a cheerful, semi-musical "wheet chu, wheet, chu..." or "chuck wheet? chuck wheet?..." monotonously repeated with rising and then falling (or vice versa). Day songs similar but somewhat more varied, a rich slow series, "wheet, chu-chu wheeet wheet, chu-chu wier wheeet..." and so on. Often noisy, groups giving sharp, metallic "tchi" and "tsit" notes; probably in alarm "whi-it" and "wheeeeet" and other notes.



Habitat. Shrubby *várzea* forest borders, second growth and vegetation along margins of oxbow lakes and rivers, bushy clearings and sometimes short distances into humid forest where light-gaps or old overgrowth clearings present; seldom far from watercourses, but usually not in early successional vegetation. Lowlands to c. 600 m, rarely to 1100 m in Peru.
Food and Feeding. Prey items in SE Peru included spiders (Araneae), caterpillars, katydids (Tettigoniidae), and various unidentified items; in Brazil, reported as eating guavas (*Psidium*), custard apples (probably *Annona* species), and fruits of Passifloraceae. Contents of three stomachs were vegetable matter, including fruit pulp, berry pits and seeds. Typically troops around in noisy groups of 3–8 individuals, occasionally more, and only infrequently in pairs, larger groups sometimes assembling in dense bushes and cane brakes to roost; groups usually composed of 2–4 adults and variable number of young or first-year birds. Groups may associate with mixed-species flocks or other tanagers such as *R. carbo*, but more often forage independently of them. Forages at various heights, mostly about eye level to middle levels, occasionally to 25 m or higher. Hops and flies short distances as it gleans or pecks arthropods, mostly from foliage; takes prey items from both surfaces of foliage, and may reach out or cling to leaves to seize items.
Breeding. Two nests found, in Jul in E Ecuador and Aug in SE Peru. Nest a bulky cup of dead dicot leaves wrapped around adjacent stems, sparsely lined with brown, thin, flexible fibres, outside diameter c. 9 cm and height 8 cm, inner cup 6·5 cm wide and 5 cm deep, suspended between numerous stiff vertical stems of grass and sedges (Cyperaceae) or in clump of regrowth branches covered with epiphytes; Ecuador nest was c. 0·2 m above ground and 0·3 m from a lake edge, the Peruvian nest more than 100 m from nearest permanent body of water but in low-lying area subject to seasonal flooding. Clutch 2 eggs, bluish with sparse, heavy black splotches overlying denser, much paler lavender flecking, measurements 22 × 17·9 mm and 22·2 × 17·6 mm. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Locally common, and widespread across W & C Amazonia. Occurs in numerous lowland national parks and eco-lodge reserves, including Yasuní National Park and Cuyabeno Wildlife Reserve (Ecuador), Manu Biosphere Reserve (Peru) and Amazonica and Serra do Divisor National Parks (Brazil). Range also encompasses vast areas of intact habitat that is not formally protected and is at extremely low risk. This species is adapted to a variety of streamside, river-edge and floodplain-edge habitats that buffer it from potential threats.
Bibliography. Burns & Racicot (2009), Descourtilz (1852), Dunning (1982), Goodfellow (1901), Greeney & Sheldon (2009), Hellmayr (1910), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Moore *et al.* (2009), Moynihan (1962c), Novaes (1958), Ogilvie-Grant (1912), Pearson (1972), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Souza (2002).

57. Crimson-backed Tanager

Ramphocelus dimidiatus

French: Tangara à dos rouge **German**: Scharlachbauchtangare **Spanish**: Tangara Dorsirroja

Taxonomy. *Ramphocelus dimidiatus* Lafresnaye, 1837, Cartagena, Colombia.
May form a superspecies with *R. melanogaster*, *R. carbo* and *R. bresilius*. Geographical variation minimal, and taxonomic review of the various described races desirable; *molochinus* possibly indistinguishable from nominate. Proposed race *isthmicus* (described from Frijoles Station, on Panama railroad) invalid, as supposed differences attributable to age and individual variation. Four subspecies provisionally recognized.
Subspecies and Distribution.
R. d. arestus Wetmore, 1957 – Coiba I, off SW Panama.
R. d. dimidiatus Lafresnaye, 1837 – Panama (except W) E across N Colombia (S to upper Cauca Valley, middle Magdalena Valley, and Norte de Santander) to W Venezuela (Maracaibo region and W slope of Andes).
R. d. limatus Bangs, 1901 – Pearl Archipelago, in Gulf of Panama.
R. d. molochinus Meyer de Schauensee, 1950 – upper Magdalena Valley, in Colombia.
Introduced on Tahiti, in Society Is.

Descriptive notes. 16 cm; c. 24–34 g. Stout-billed tanager with lower mandible notably enlarged at base. Male nominate race has head, mantle, throat and chest deep blackish maroon-red, becoming redder on back and bright red on lower back, rump and uppertail-coverts; feathers of head very short, dense and plush-like, feathers of back glistening; entire wing and tail black; breast and lower underparts bright red, thigh and narrow patch in centre of belly black; iris reddish-brown; upper mandible dusky, lower mandible gleaming bluish-white with dusky tip; legs grey to blackish. Female resembles male, but much duller, foreparts dull dusky brown, tinged reddish, and becoming dull reddish on back and almost black on throat; usually some dull pinkish-red around bill; lower back, rump, and breast and belly red, as

On following pages: 58. Huallaga Tanager (*Ramphocelus melanogaster*); 59. Silver-beaked Tanager (*Ramphocelus carbo*); 60. Brazilian Tanager (*Ramphocelus bresilius*); 61. Scarlet-rumped Tanager (*Ramphocelus passerinii*); 62. Cherrie's Tanager (*Ramphocelus costaricensis*); 63. Flame-rumped Tanager (*Ramphocelus flammigerus*); 64. Lemon-rumped Tanager (*Ramphocelus icteronotus*).

on male but considerably duller; upper mandible dusky grey, becoming dark brownish-grey basally, lower mandible dull dark brownish-grey. Immature is very like female, but duller; subadult male much like female. Races differ minimally: *limatus* male is like nominate, but black of belly less extensive and red in plumage, especially on rump, more scarlet (less orange); *arestus* is darkest race, male with black of belly reduced as in previous, but deeper red throughout, especially on belly, female darker than others; *molochinus* differs little from nominate, male throat and chest slightly darker red, and crown and nape perhaps slightly darker crimson. Voice. Dawn and day song in Venezuela, typically from semi-exposed perch c. 3–12 m up, a long, slow series of rather clipped single or double notes, "reet, skréa, seek, reé-a, séea, bz-weet, wit-weet, fzeet, reéza, bzeep, skeéa...", slightly buzzy, the notes rising and falling and continuing for up to several minutes without clear break; dawn song may be given mainly during breeding season. Commonest call during foraging a nasal "chank", much like that of *R. carbo*; also other notes, given in context of greeting, alarm and threat.

Habitat. Thickets, shrubby clearings, cultivated areas, parks, gardens, and moist to humid forest borders; smaller numbers in dry zones in scrubby second growth. Normally not inside humid forest, but on Coiba I (Panama), probably in absence of competitors, does occur inside forest. Readily colonizes forested areas opened up for cultivation. Lowlands to c. 1620 m in Panama; to 1300 m in Venezuela; to 1700 m, very locally (e.g. Bogotá) to at least 2600 m, in Colombia.

Food and Feeding. Of six stomachs examined, three contained only vegetable matter and three contained both animal and vegetable matter; contents included soft seeds, grass seeds, larvae, lepidopterans, a bug (Hemiptera) and a spider (Araneae). Almost always conspicuous and noisy, and in monospecific groups that troop about in undergrowth or middle levels along wooded borders, but in pairs or families when breeding; several sometimes associate with small mixed-species flocks. Forages by hopping and peering in foliage, usually fairly low, for fruit and insects. Will come to feeding trays for fruit. Overall, behaviour much like that of *R. carbo*. May gather in large numbers to roost, e.g. more than 50 in citrus grove in W Venezuela in Jan; several dozen at roost in Panama.

Breeding. Breeding reported in Feb–Jun in Panama; in Colombia, juvenile seen in Feb and eggs in May in Colombia, and 14 breeding-condition birds Apr–Aug from Santa Marta area S to Huila, others in Nov and Dec. Nest built by female, a cup of dead leaves and coarse plant fibres, with lining of finer material, usually well concealed 1–3 m up in bush or thick foliage of small tree or shrubbery. Clutch 2 eggs, laid on consecutive days, pale blue or greenish-blue, sparingly marked with deep chocolate-brown, black or lilac, most heavily at large end; incubation by female alone, no information on duration; chicks fed by both sexes, in at least one case female brought mainly insects and male brought berries; young leave nest at 10–11 days, unable to fly, and remain hidden in nearby bush; offspring of previous generation may remain with nesting pair and sometimes assist with feeding of young.

Movements. Resident; no local or seasonal movements reported.

Status and Conservation. Not globally threatened. Fairly common to locally common in variety of forest-edge, shrubby and settled areas. Since 1990 or earlier, in Colombia, a small population has been resident in Bogotá in Jardín Botánico, Parque de Niza and elsewhere, and more recently also in Plaza de Tenjo; originally, was only an occasional visitor to Sabana de Bogotá. Occurs in a number of parks and reserves, and its range encompasses large amounts of unprotected but suitable habitat. Adapted to many kinds of second growth and disturbed habitats, a fact which buffers this species against potential threats and, in many cases, allows it to profit and expand as forested areas are opened up and settled. On Tahiti (Society Is), where introduced at some time prior to 1940, uncommon in coastal areas on W side of the island.

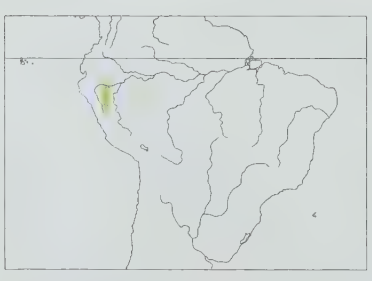
58. Huallaga Tanager

Ramphocelus melanogaster

French: Tangara du Huallaga **German**: Schwarzbauchtangare **Spanish**: Tangara del Huallaga
Other common names: Black-bellied Tanager



Taxonomy. *Rhamphopis melanogaster* Swainson, 1838, Moyobamba, San Martín, Peru.

May form a superspecies with *R. dimidiatus*, *R. carbo* and *R. bresilius*. A geographical replacement of *R. carbo*, with very slight range overlap in Marañón drainage (no known overlap in Huallaga Valley), and some evidence of intergradation; molecular analysis indicates that levels of divergence between the two (1·1%) are lower than those generally found for other species in genus (2·4–4·0%). Races differ minimally. Two subspecies currently recognized.

Subspecies and Distribution.

R. m. melanogaster (Swainson, 1838) – N Peru in San Martín and Huánuco (to confluence of R Huayabamba and R Huallaga) S to NW Ucayali (R Ucayali).

R. m. transitus J. T. Zimmer, 1929 – EC Peru (E slope drainage) in upper Huallaga and Chinchao Valleys.

Descriptive notes. 17 cm; one male 25 g. Male nominate race has lustrous dark crimson head, becoming deep black on mantle and back, bright red lower back to uppertail-coverts; upperwing and tail black; throat and chest deep red, red extending to breast, where separated rather abruptly from brighter red of lower breast and flanks; centre of lower breast and belly black; iris reddish-brown; upper mandible dusky, lower mandible white with dusky tip; legs dusky grey. Female is mainly dusky reddish-brown above with bright red rump and uppertail-coverts, has lower throat and chest dusky, tinged reddish, and rather sharply separated from cinnamon-red breast and lower underparts; usually a narrow area of dull red on base of forehead, lores, ocular area, basal malar area and chin, forming distinctive area surrounding bill, also base of upper mandible and basal half of lower mandible paler than on male, dull bluish-grey; distinguished from very similar female of *R. carbo* by brighter red colour on rump and uppertail-coverts, also pinkish-red area around bill (present on most, but not all, females; usually lacking or indistinct on *R. carbo* female). Immature undescribed. Race *transitus* is much like nominate, but male rump brighter red, and upper throat paler red and less sharply set off from breast. Voice. Day song a short, fairly musical series of repeated phrases, similar to that of *R. carbo*. Call note a slightly burry "chwipo" or "chwick", much like that of congeners; similar note used in alarm.

Habitat. Forest edge, shrubby clearings, second growth, river borders, cultivated areas and gardens, often in vegetation around settled areas; c. 800–2100 m.

Food and Feeding. Few data. Diet and foraging behaviour apparently much as for *R. carbo*. Occurs in small flocks of 6–8 individuals.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Huallaga Valley Secondary Area. Locally common. Found in a few protected areas, including Río Abiseo (in San Martín) and Tingo Maria National Park (in Huánuco). Occurs in second growth and disturbed habitats, something which buffers this species against potential threats and, in many cases, allows it to benefit and expand as forested areas are opened up and settled. Currently extending its range to extreme NW Ucayali (R Ucayali drainage) E of Tingo Maria, doubtless in response to deforestation and clearance. Despite its small range, this species seems unlikely to be facing any risks in the immediate future.

Bibliography. Burns & Racicot (2009), Clements & Shany (2001), McCarthy (2006), Meyer de Schauensee (1966, 1970a), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Tallman (1974), Zimmer (1930, 1945).

59. Silver-beaked Tanager

Ramphocelus carbo

French: Tangara à bec d'argent **German**: Purpurtangare **Spanish**: Tangara Picoplata
Other common names: Maroon Tanager, Common Silverbeak

Taxonomy. *Lanius* (*Carbo*) Pallas, 1764, Suriname.

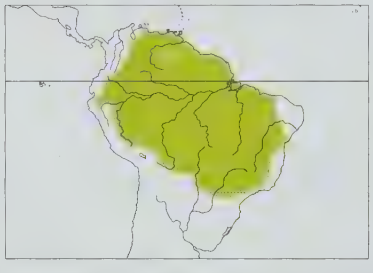
May form a superspecies with *R. dimidiatus*, *R. melanogaster* and *R. bresilius*. Molecular analysis indicates that levels of divergence between this species and *R. melanogaster* (1.1%) are lower than those generally found for other species in genus (2·4–4·0%); the two overlap slightly in range in N Peru (Marañón drainage), with some evidence of hybridization. Has hybridized with *R. bresilius* in E Brazil (SE Minas Gerais). Eight subspecies recognized.

Subspecies and Distribution.

R. c. capitalis J. A. Allen, 1892 – NE Venezuela (Anzoátegui E to Paria Peninsula, S to Monagas and Delta Amacuro).

R. c. magnirostris Lafresnaye, 1853 – SE Sucre, in NE Venezuela; Trinidad.

R. c. venezuelensis Lafresnaye, 1853 – E base of Andes in N & W Venezuela (Falcón E to Miranda, S to Táchira) and Colombia (Arauca, Boyacá).



R. c. unicolor P. L. Sclater, 1856 – E base of Andes in Colombia (from Casanare region S to Meta).

R. c. carbo (Pallas, 1764) – SE Colombia, E Ecuador, E Peru (S to Ucayali), Venezuela S of R Orinoco, the Guianas, and N, W & C Brazil (S to N Mato Grosso).

R. c. connectens Berlepsch & Stolzmann, 1896 – SE Peru and adjacent NW Bolivia.

R. c. atrosericeus d'Orbigny & Lafresnaye, 1837 – N & E Bolivia.

R. c. centralis Hellmayr, 1920 – E Brazil (C Mato Grosso E to Bahia, Minas Gerais and N São Paulo) S to NE Paraguay.

Descriptive notes. 16–17 cm; 21·5–27 g (*atrosericeus*), 23·5–37·5 g (other races). Dark tanager with heavy bill, lower mandible greatly expanded basally. Male nominate race has head, neck and throat deep carmine (feathers short, dense and plush-like); upperparts, including uppertail-coverts and upperwing-coverts, carmine-black, contrasting somewhat (in good light) with redder head and neck; flight-feathers and tail dusky black; dark red of throat deepens to rich deep crimson on chest, and to deep black (but with dark crimson tinge) on lower underparts and undertail-coverts; iris reddish-brown; upper mandible dark blue-grey, lower mandible gleaming silvery white and usually with small dark tip; legs dark horn-grey. Female is mainly rich dark rusty red above, slightly redder on lower back and rump, wing dusky, upperwing-coverts and tertials edged rufescent brown, tail dusky; rich reddish-brown to warm brown below, greyish tinge on breast; bill entirely brownish-dusky. Immature male is very like female; older immature brighter. Races differ mainly in plumage tone, generally brighter in N and darkest in S: *capitalis* male has upperparts pure black, only head deep red, chin to breast deep crimson, female has redder rump and uppertail-coverts and more reddish coloration on lower underparts; *magnirostris* is much like nominate, but with larger, heavier bill, male with white base of lower mandible larger, female more uniformly reddish below; *venezuelensis* male differs from nominate in having red parts of plumage on average brighter red, upperparts black with tinge of dark red, deep crimson of chin to breast changes to dull charcoal (dull blackish) on lower underparts; *unicolor* male is very close to nominate, but red foreparts on average slightly brighter and rear parts more uniformly blackish, with back and belly only slightly darker than breast; *connectens* male is slightly paler above and below than nominate, and with brownish tinge (less red) on back, rump and lower underparts, female paler than nominate female; *centralis* male is much like previous, but throat slightly darker red; *atrosericeus* is darkest of all races, male essentially velvety black with dark scarlet hue on head to mid-breast, sharply separated from rest of underparts, female distinctively plain black-brown all over, sometimes with some dull red edges on belly feathers. Voice. Dawn song (occasionally later in day) an energetic and semi-musical but rather repetitive series of phrases without much richness, "tu tu tweep, chip-tup tweep, tu tu tweep, chip, sput, seek..." and so on; some individuals sing leisurely, even simpler, repetitive "spit weet, sput, wheer..." over and over. Day song much like dawn song, but shorter, less sustained, and given infrequently, e.g. "chick chi-ti-wee" or sometimes just a single note repeated again and again. Call, given almost constantly as groups troop around edges of clearings, a loud, metallic "chank".

Habitat. Bushy forest borders, overgrown clearings, second growth, shrubbery around habitations, and bushy vegetation along riverbanks in humid areas. Sometimes in rather dry scrubby or degraded areas. May occur in open woodland, but not inside dense forest, although occasionally moves across top of forest canopy. Scarce or locally absent in *llanos* of C Venezuela and adjacent E Colombia. Lowlands to c. 1200 m in most areas, but locally higher following clearing and deforestation; to 1900 m in Venezuela, and at least 2000 m in Peru (Urubamba Valley).

Food and Feeding. Arthropods and fruit; occasionally eats flowers (possibly for nectar) or drinks nectar. About half of diet is fruit, especially melastome berries; in Trinidad reported as taking 40

species of fruit, 64% of which was of *Miconia* and *Clidemia* berries. Of 31 stomachs examined, 14 contained only vegetable matter, seven only animal matter and ten both; contents included *Cecropia* fruit, seeds, caterpillars, beetles (Coleoptera) including snout beetles (Curculionidae) and leaf beetles (Chrysomelidae), spiders (Araneae), orthopterans, ants (Formicidae), and bugs (Hemiptera). Other stomachs contained berries of Solanaceae and Loranthaceae, cactus fruits (*Cerus*) and winged termites (Isoptera). Of 588 observations in Trinidad, 50% involved foraging for insects, 45% fruit-eating, and 5% at flowers; data similar in Peru. Smaller fruits swallowed whole; larger ones mashed, or pieces pecked from them, and may mash the pulp and discard the tough skin of some fruit species. Travels in groups that are noisy, engaging and omnipresent. Bands of 4–10 individuals, occasionally more, troop noisily about in undergrowth along forest borders or in gardens and clearings; may briefly join mixed-species flocks along borders or briefly associate with other birds in fruiting trees and shrubs. Often acts in quite nervous manner, with much agitated flicking of wings and tail, as it peers in foliage for fruit and insects. Forages from near ground to c. 12 m up, also regularly ascends into canopies 25 m high for fruit, and in general forages higher up when with mixed-species flocks. Hops rapidly and heavily in foliage, and chases disturbed and fleeing insect prey. In Trinidad, 77% of insect-seeking was on foliage, 13% in grass and weeds, 7% in aerial sallies, and remainder on seedheads, twigs and branches. Has been noted at army-ant swarms in Brazil and elsewhere.

Breeding. Breeding reported in Jan–Mar in E Colombia, Apr and May in Venezuela, Dec–Sept in Trinidad, Dec–Aug in Suriname and Jul and Aug in French Guiana; in Brazil, Sept–Feb in Pará and Nov in Mato Grosso. Nests sometimes close together. Sometimes co-operative breeder; helpers may attend young. Pairs seem not to defend territories against conspecifics; in various displays, male points bill upwards to maximize exposure of silvery colour. Bulky deep cup-nest of dead leaves and plant fibres, sometimes with a few green leaves on outside, placed c. 1–3 m above ground, occasionally higher, in bush; nest sometimes reused. Clutch 1–3 eggs, usually 2, greenish to bluish with blackish, brown, grey and/or lilac markings, especially at larger end; incubation by female, period c. 12 days; chicks fed by both parents, no information on duration of nestling period.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Common and widespread E of Andes and across Amazonia. Occurs in parks and reserves throughout its range, and is found also in vast areas of unprotected but suitable habitat. Adapted to many kinds of second growth and disturbed habitats, which buffers this species against potential threats and allows it to profit and expand as forested areas are opened up and settled.

Bibliography. 60. Brazilian Tanager

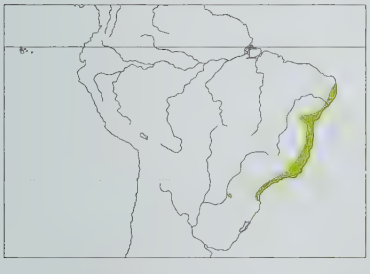
Ramphocelus bresilius

French: Tangara du Brésil **German**: Brasiltangare **Spanish**: Tangara Brasileña



Taxonomy. *Tanagra bresilia* Linnaeus, 1766, "in India Occidentali et Orientali"; error = Pernambuco, eastern Brazil.

May form a superspecies with *R. dimidiatus*, *R. melanogaster* and *R. carbo*. Hybrids between this species and *R. carbo* reported from E Brazil (Rio Doce area of Minas Gerais), but molecular analyses show that differentiation between these two taxa is typical of expected values for well-differentiated species (2·4–4·0%). Two subspecies recognized.

Subspecies and Distribution.

R. b. bresilius (Linnaeus, 1766) – coastal E Brazil from Paraíba S to Bahia (Ilhéus).

R. b. dorsalis P. L. Sclater, 1855 – SE Brazil from E Minas Gerais, S Bahia and Espírito Santo S to NE Santa Catarina; extreme NW Argentina (N Misiones).

Descriptive notes. 18 cm; 27·9–35·5 g. Typical tanager with heavy bill, lower mandible greatly expanded at base. Male nominate race is mainly rich glistening red, feathers of head, neck and throat short, dense and plush-like, back very slightly darker red than rest of plumage, and central back sometimes with small amount of black showing (feathers black basally); wing and tail black, median upperwing-coverts sometimes with inconspicuous red tips; iris reddish brown; bill mostly blackish, basal half of lower mandible gleaming white; legs dull brown to slate-grey. Female is rather plain, mainly greyish-brown on head, throat, neck and entire upperparts, including wing-coverts, flight-feathers and tail; forecrown and rump somewhat tinged reddish; greyish-brown of throat merges into dull brownish-red on breast, belly and undertail-coverts; bill dusky brown. Immature male is like female, but bill black (not brownish); older immature acquires bright red-and-black plumage of adult male in second year, but may show dusky mottling on back, rump and uppertail-coverts. Race *dorsalis* is similar to nominate, but back of male is darker red. Voice. Song described as a melodious and leisurely "jewle-jewle-jewle...", repeated. Harsh chattering notes heard from small groups. Possible dawn song from captive bird a long series of "wheeeee" or "wheee-eeee" notes. Captive gave possible whisper song consisting of "chuup chuh-wheeee" phrases combined with call notes in a melodious jumble lasting c. 10 minutes. Various call notes include hard "jep, jip, "ist" and "sst-sst".

Habitat. Variety of shrubby non-forest habitats, including overgrown clearings, forest borders, parks, gardens, city plazas, and edges of swampy woodland and marshes; often near water, as well as in shrubbery close to ocean. Lowlands; small numbers up to c. 800 m.

Food and Feeding. Reported as eating pulpy fruits, including *Eugenia*. Of five stomachs examined, two contained only vegetable matter, two only animal matter and one both; contents included seeds, fruit pulp, insects, and a small quantity of white sand. Found in pairs much more than in groups (unlike many other in genus). Flies low between bushes, and tends to remain hidden during middle of day.

Breeding. Breeding reported in Nov in São Paulo and Rio de Janeiro. Nest an open woven cup of grasses, vines and fibres, placed in bush or low tree or hidden among clumps of marsh grass. Clutch 2–3 eggs, greenish-blue, sparingly marked with black and grey; in captivity, incubation by female only, period 13 days, chicks fed by both adults. Nest frequently parasitized by Shiny Cowbird (*Molothrus bonariensis*).

Movements. Reported as gathering in flocks in austral winter, suggesting that those in extreme S of range may undertake some minor migratory movements. More documentation required.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common; almost always in small numbers. Records in NW Argentina (at least one old record and a few recent ones) possibly refer to escaped cagebirds; research needed. Occurs in numerous protected areas in E Brazil, including, among others, Itatiaia, Tijuca and Serra dos Órgãos National Parks and Sooretama and Poço das Antas Biological Reserves. Also survives in urban and settled areas. Reported as relatively numerous in coastal lowlands of S Rio de Janeiro and NE São Paulo, but in declining numbers N in Espírito Santo and Bahia, where activities of bird-trappers may affect numbers. Utilization of a variety of habitats, including many second-growth and disturbed habitats, buffers this species against potential threats. In severely deforested areas some local populations may prove more sensitive, or have disappeared. The species does not appear likely to be at risk in immediate future.

Bibliography. Berla (1944), Burns & Racicot (2009), Castiglioni & Gonzaga (1999), Castiglioni *et al.* (1995), Chebez *et al.* (1984), Descourtilz (1852), Diamond & Lovejoy (1985), Dunning (1982), Euler (1900), Forbes (1881), Goeldi (1894), Guimarães (1926), Ihering (1900), McCarthy (2006), Mitchell (1957), Moojen *et al.* (1941), Moynihan (1962b), Narosky & Di Giacomo (1993), Norgaard-Olesen (1974), Ogilvie-Grant (1912), Parker & Goerck (1997), Peixoto Velho (1932), de la Peña & Rumboll (1998), Ridgely & Tudor (1989, 2009), Santos (1948), Sazima *et al.* (1993), Schubart *et al.* (1965), Sick (1985, 1993), Snethlage & Schreiner (1929), Souza (2002).

61. Scarlet-rumped Tanager

Ramphocelus passerinii

French: Tangara à croupion rouge **German**: Passerinitangare **Spanish**: Tangara Terciopelo
Other common names: Passerini's/Song Tanager

Taxonomy. *Ramphocelus Passerinii* Bonaparte, 1831, Cuba; error = Guatemala.

Often treated as conspecific with *R. costaricensis*, but recent DNA studies suggest that they can be regarded as separate species. DNA studies indicate that both are monophyletic and, although levels of divergence within the two taxa (0·1%, 0·6%) are much less than divergence between them (1·8%), this level of interspecific divergence is lower than that between most species of tanager (c. 2·4–4·0%); also, visual differences between the two are minimal (involving mainly females), and only minor vocal differences have been demonstrated; further evaluation of these taxa may be required. Monotypic.

Distribution. SE Mexico (SE Veracruz, S Tabasco and N Chiapas) E to C Guatemala and Belize, S on Caribbean coast to Costa Rica and NW Panama (Bocas del Toro).

Descriptive notes. 16 cm; 25·5–37 g. Thick-billed tanager with slightly enlarged base of lower mandible. Male is deep velvety black from head to back, upperwing-coverts, flight-feathers, tail and underparts, black feathers of head short, dense and plush-like; slightly elongated feathers of lower back, rump and uppertail-coverts bright scarlet; iris deep carmine to dark brown; bill pale blue-grey, black tip; legs dark horn-grey. Female has head brownish-grey, upperparts yellowish-brown with olive tinge (not in strong contrast to head), rump paler, upperwing-coverts dusky, broadly edged yellowish-olive, flight-feathers dusky, edged yellowish-olive, tail dusky; throat greyish-buff, becoming deep ochraceous, tinged olive, on breast and paler olive-tinged ochraceous on lower underparts. Immature male resembles female; older male acquires irregular patches of black mottling in plumage. Voice. Infrequently heard song a simple series of phrases of 2–4 notes, given a few times at dawn by male, e.g. "wah-wait chu", repeated, or "vireo viree vireo viree viree...", and occasionally interrupted with high squeaky "witchy-wit" notes. Male may sing initially from roost, later from exposed position with tail and wings drooped, revealing scarlet rump feathers; sings shorter phrases than, and not nearly so often or so persistently as, *R. costaricensis*. Variety of calls include sharp "ac" or "wac", dry scratchy "chuck", dry "pzzt", and sharp "whip" in alarm; sharp descending chatter in interactions.

Habitat. Inhabits second growth, dense humid thickets, bushy forest borders, overgrown pastures, gardens and shrubbery around homes and settlements, bushy borders of fields, occasionally a short distance inside forest; favours very humid zones. Present from lowlands up to c. 1200 m, occasionally higher.

Food and Feeding. Lives in pairs, families and little groups of up to c. 12 individuals. Move about actively in thick foliage, call and chatter, often fly across small clearings, and are generally conspicuous. Individuals, pairs or groups sometimes associate with mixed-species flocks along wooded borders, and readily mob noisily. Forage low, usually less than 7 m up, but may go much higher with mixed-species flocks, and also regularly drop to the ground in openings. Eat a wide variety of fruits and insects. Especially fond of melastomes and several species of arillate fruits, and also occasionally eats *Cecropia* fruit. Readily visits feeding platforms for fruit.

Breeding. Season early Mar through Jul in Panama. Nest built by female alone; three nests at Almirante (Panama) a compact, thick-walled, strongly woven cup, base of large leaves, sides of fibres and rootlets, lining of fine delicate hair-like fibres, one measured 120 × 120 mm with inside depth of 45 mm; nests mostly 3–7 m above ground and concealed in dense shrub or thicket. Clutch (from five nests in SE Nicaragua) 2 eggs, pale greyish-blue marked with small irregular black spots or fine irregular lines, mainly around larger end; incubation entirely by female, period 12 days; nestling period 11 or 12 days. May breed in immature plumage.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Uncommon to locally common. A generally widespread and familiar species of Caribbean slope of Central America. Occurs in a number of parks and reserves throughout its range, including e.g. Cascadas de Agua Azúl and Palenque National Park (Mexico), Tikal National Park (Guatemala), Cockscomb Basin Wildlife Reserve (Belize), Capiro–Calentura National Park (Honduras), Indo-Maíz Biological Reserve (Nicaragua) and La Selva Biological Reserve (Costa Rica). Also found in areas of suitable habitat that do not have formal protection, especially in Guatemala and Belize. This species is adapted to many kinds of second growth and disturbed habitats, which buffer it against potential threats and allow it, at least locally, to profit and expand as forested areas are opened up and settled. Several Caribbean areas,

e.g. in Costa Rica, are so severely deforested that some populations have declined or disappeared locally.

Bibliography. 62. Cherrie's Tanager

Ramphocelus costaricensis

French: Tangara du Costa Rica **German**: Cherrietangare **Spanish**: Tangara Costarricense

Taxonomy. *Ramphocelus costaricensis* Cherrie, 1891, Pozo Azul, Costa Rica.

Often treated as conspecific with *R. passerinii*, but recent DNA studies suggest that the two can be regarded as separate species. DNA studies indicate that both are monophyletic and, although levels of divergence within the two taxa (0·1%, 0·6%) are much less than divergence between them (1·8%), this level of interspecific divergence is lower than that between most species of tanager (c. 2·4–4·0%); also, visual differences between the two are minimal (involving mainly females), and vocal differences only minor; further evaluation of these taxa is desirable. Monotypic.

Distribution. Pacific slope of Costa Rica from Puntarenas (C & S regions) and NE Central Valley S to W Panama (Chiriquí and Veraguas).

Descriptive notes. 16 cm. Thick-billed tanager with slightly enlarged base of lower mandible. Male is deep velvety black from head to back and on wings, tail and underparts, black feathers of head short, dense and plush-like; slightly elongated feathers of lower back, rump and uppertail-coverts bright red; iris crimson to dark maroon; bill pale blue-grey, black tip; legs dark horn-grey. Distinguished from extremely similar *R. passerinii* in having rump very slightly tinged orange, although the two appear identical in the field (and barely separable in the hand). Female has head dark greyish-brown, upperparts brown, rump dark orange, upperwing and tail dusky brown, chest dark tawny-orange, ochraceous lower underparts; differs from female *R. passerinii* mainly in orange rump, broad and diffuse dark tawny-orange band across chest contrasting strongly with paler lower underparts, and general darker appearance. Immature resembles female; subadult male may show patches of black and red in plumage. Voice. Song, mainly at dawn from about Feb to mid-Aug in SW Costa Rica, a repetition of simple phrase of few notes, e.g. "viree-viree-vireo-vireo-vireo,...", continued for several minutes. At dawn male sings from perch close to roost, but after sunrise from exposed perch on top of bush or low tree; when singing, droops wings and tail and ruffles feathers of back to expose scarlet colour more fully. Sings more frequently and more persistently than does *R. passerinii*. Commonest calls a nasal "ac" or "wac", given almost constantly by both sexes when foraging or engaged in other activities; less frequently a sharp, dry "pzzt" on taking flight or to call mate; in excited greeting individuals may give an odd "zzt not churry not churry", sharply and rapidly; sharp "whip" in alarm.

Habitat. Second growth, dense humid thickets, bushy forest borders, overgrown pastures, gardens and shrubbery around homes and settlements, bushy borders of fields, occasionally a short distance inside forest; commonest in humid zones, but occurs also in moist sites and even dry ones. Lowlands to c. 1200 m, occasionally as high as 1700 m.

Food and Feeding. Wide variety of fruit and arthropods taken. Fruits eaten include melastomes, arillate fruits, *Cecropia*, and many kinds of fruit from feeders; arthropod prey includes caterpillars and spiders (Araneae) in foliage and grasshoppers (Caelifera) taken from ground. Nestling diet insects and some fruit. Occurs in pairs when breeding, but in small groups of varying sizes during rest of year, when sometimes joins small mixed-species flocks; throughout most or all of year may roost in small groups, sometimes up to a dozen together, low in dense shrubbery or garden. Forages mostly low, usually less than 7 m up, but higher when with a mixed flock. Takes insects by hopping and searching in foliage and pecking or lunging; occasionally sallies for prey, e.g. flying termites (Isoptera). Has been reported at an army-ant (Formicidae) swarm in second growth. Pairs or groups apparently do not defend a foraging territory.

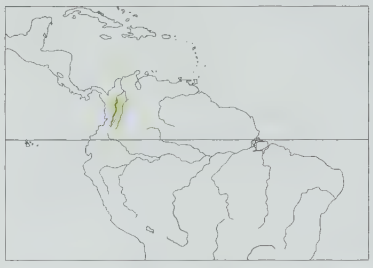
Breeding. Reported in Mar–Sept, but few nesting attempts after Jul, in Costa Rica (El General Valley); rarely two broods, but may make second nesting attempt if first one in season fails. Despite preponderance of female-plumaged birds, appears to be monogamous; occasionally a third, dull-plumaged individual may accompany adults. Inter-nest distance sometimes as little as c. 1 m. Apparently does not defend a breeding territory. Nest built by female alone, accompanied by mate, and female may steal material from neighbouring nests; an open cup of dead leaves, fibres and grass, sometimes with green fern on outside, placed up to 6 m above ground (about two-thirds of all nests 1–4 m up) and concealed in bush or small tree, or in tall grass, ferns or sugar cane. Clutch 2 eggs, rarely 3, pale blue to pale grey with black, brown or pale lilac markings, usually in wreath at larger end; incubation by female alone, period 12–13 days; chicks fed by both parents, female typically bringing more food than male, often twice as much, nestling period c. 11–13 days; young leave nest unable to fly, hide in nearby bush. In Costa Rica, c. 25% of nesting attempts produce at least one fledgling; main predators appear to be snakes and toucans (Ramphastidae).

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in South Central American Pacific Slope EBA. Common within limited range. Females and female-plumaged birds outnumber males by c. 3:1. Occurs in a few protected areas, including Corcovado National Park (Costa Rica) and Volcán Barú and Chiriquí National Parks (Panama). The fact that this species is adapted to a variety of second growth and disturbed habitats buffers it against potential threats and allows it, at least locally, to profit and expand as forested areas are opened up and settled. No near-term risks known.

Bibliography. Anon. (1998), Barrantes & Hidalgo (2004), Burns & Racicot (2009), Davis (1972), Garrigues & Dean (2007), Hackett (1996), Isler & Isler (1999), Krueger & Williams (2006), Ridgely & Gwynne (1989), Skutch (1950, 1954, 1972, 1980a), Stiles & Skutch (1989), Wetmore *et al.* (1984).

63. Flame-rumped Tanager



Ramphocelus flammigerus

French: Tangara flamboyant **German**: Feuerbürzeltangare **Spanish**: Tangara Flamigera

Taxonomy. *Ramphopis flammigerus* Jardine and Selby, 1833, Antioquia, Colombia.

Usually treated as conspecific with *R. icteronotus*, and, despite striking visual differences, genetic differences between the two taxa apparently minimal; also, the two now apparently interbreed freely in W Andes (along a relatively narrow but apparently stable band at middle elevations near crest of, or on, upper Pacific slope), where recent deforestation has permitted them to expand ranges and to meet. Differences between them, however, seem comparable to, and visually much more obvious than, those between *R. passerinii* and *R. costaricensis*, which are now regarded as two separate species. Present species is also very similar in appearance to both *R. passerinii* and *R. costaricensis*, although geographically well isolated from them; furthermore, it shows a high sequence divergence (4·7%) from these two species, indicating its genetic isolation. Monotypic.

Distribution. W Colombia on both slopes of Cauca Valley from C Antioquia S to Cauca, the upper Patía Valley in SW Cauca, and locally on W slope of Andes (mostly as expansion across low passes from Cauca Valley, from Risaralda, on upper R San Juan, S to NW Nariño); also W slope of E Andes above Magdalena Valley, in Santander.

Descriptive notes. 18 cm. Male is almost entirely deep black; head velvety black, with feathers very short, dense and plush-like; middle back to rump and uppertail-coverts glistening flame-scarlet; iris crimson to dark maroon; bill light blue-grey, black tip; legs dark horn-grey. Differs from very similar *R. passerinii* and *R. costaricensis* in having red of upperparts more scarlet (less deep red) and more extensive, reaching farther up on back. Female is blackish-brown to brown above, usually with slight mottled appearance on back, and with rump and uppertail-coverts reddish-orange; side of head brown, often somewhat mixed with dusky and grey, throat dingy greyish-yellow, underparts pale yellow, large diffuse reddish-orange patch on chest forming ill-defined band, undertail-coverts usually dull red or mixed red and yellow. Immature male is like female; subadult male extensively mottled black. Voice. Dawn song, delivered from top of low bush or sapling, an energetic series of mostly 2-note or 3-note phrases repeated over and over as male perches upright, with rump exposed and puffed out and wings drooped. Commonest call a loud slightly nasal "chink". Vocalizations similar to those of *R. icteronotus*.

Habitat. Humid forest borders, second growth, old pastures, shrubby areas, borders of fields, and bushes and vegetation around habitations; readily invades new forest clearings following deforestation. In moist or moderately humid to very humid areas. From 800 m to c. 2000 m.

Food and Feeding. Fruit and arthropods. Most often seen singly or in pairs, and less often in small family groups; unlike *R. icteronotus*, seems not to troop around in noisy groups. Perches on branches to take fruits, and perches on and pecks at large fruits. Occasionally sallies to seize aerial insects; also picks insects from foliage and grass. Behaviour otherwise much like that of *R. icteronotus*.

Breeding. Nest found in Feb in Calima Valley (W Valle) and four breeding-condition birds in Jul near Popayán (upper Cauca Valley). Calima Valley nest an open cup placed in low weeds. Eggs pale blue, marked with dark brown or black spots and sometimes with a few short lines, which may coalesce in wreath around large end. No other information.

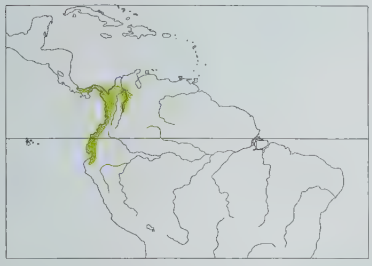
Movements. Movements (possibly by wandering individuals) from E slope of W Andes to W slope not well documented; present in Anchicayá Valley (1050 m) only in Nov–Jan in 1972–1973.

Status and Conservation. Not assessed. Usually treated as conspecific with *R. icteronotus*. Restricted-range species: present in Colombian Inter-Andean Valleys EBA. Uncommon to locally fairly common. On Pacific coast seems nowhere to be as locally numerous as *R. icteronotus*, and distribution may be somewhat patchy. Occurs in several inter-Andean protected areas, including Reserva Hidrográfica de Río Blanco (in Caldas), Reserva Reinita Cielo Azul, Lago de Sonso Natural Reserve and Bosque Yotoco Reserve. This species' adaptation to a variety of second-growth and disturbed habitats buffers it against potential threats and allows it, at least locally, to profit and expand, especially to higher elevations, as forested areas are opened up and settled. Short-term risks seem minimal.

Bibliography. Burns & Racicot (2009), Chapman (1917), Dunning (1982), Hellmayr (1936), Hilty (1997), Hilty & Brown (1986), Isler & Isler (1999), McCarthy (2006), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Ogilvie-Grant (1912), Plath (1946), Restall *et al.* (2006), Salaman *et al.* (2008), Sclater & Salvin (1879), Sibley (1958).

64. Lemon-rumped Tanager

Ramphocelus icteronotus



French: Tangara à dos citron **German**: Gelbrückentangare **Spanish**: Tangara Culigualda
Other common names: Yellow-rumped Tanager

Taxonomy. *R[h]amphocelus icteronotus* Bonaparte, 1838, Ecuador.

Usually treated as conspecific with *R. flammigerus*, and, despite striking visual differences, genetic differences between the two taxa apparently minimal; also, the two now apparently interbreed freely in W Andes of Colombia (along a relatively narrow but apparently stable band at middle elevations near crest of, or on, upper Pacific slope), where recent deforestation has permitted them to expand ranges and to meet. Differences between them, however, seem comparable to, and visually much more obvious than, those between *R. passerinii* and *R. costaricensis*, which are now regarded as two separate species. No races of present species described, but females and immatures from W Ecuador are more olive, less brown or grey, above than those farther N, and one individual from Panama and one from Ecuador showed a molecular-sequence divergence of 2·2%, approaching the levels at which many full species are recognized; further research required. Treated as monotypic.

Distribution. Panama from Caribbean slope in Bocas del Toro E across both slopes (from foothills of Veraguas) to Colombia (N base of W Andes, lower Cauca Valley and E to middle Magdalena Valley from Santander S to N Tolima, and on W slope of E Andes) and S along Pacific coast to SW Ecuador (Guayas, El Oro, W Loja) and adjacent NW Peru (Tumbes).

Descriptive notes. 18 cm; 29·6–35·6 g. Male is almost entirely deep black; feathers of head short, dense and plushy, resembling black velvet; middle back to rump and uppertail-coverts glistening lemon-yellow; iris crimson to dark maroon; bill light bluish-grey, black tip; legs dark greyish-horn. Differs from otherwise almost identical *R. flammigerus* in having lower back to uppertail-coverts brilliant lemon-yellow, instead of red. Female is greyish-brown above, sometimes tinged olive, side of head generally dingy greyish-brown; lower back, rump and uppertail-coverts pale yellow; throat dull whitish, becoming clear pale yellow on underparts. Immature male closely resembles female; older immature male mottled or blotched with black, especially on head and breast, as it gradually acquires adult plumage. Voice. Dawn song, from top of low bush or sapling, an energetic

and somewhat musical "tseee-yah" repeated tirelessly as male sits rather upright. Songs, sometimes varied slightly, or with occasional harsh notes added, given only during breeding season in Panama, but most of year in W Colombia (where climate far less seasonal); as with congeners, singing male droops wings and tail and slightly ruffles back and rump feathers to display as much colour as possible. Often rather noisy, groups constantly uttering loud, slightly nasal "chink" as contact notes and more rapidly in alarm; variety of other notes, some hoarse, others disyllabic, and rattle-like calls.

Habitat. Thickets, bushy forest borders, overgrown clearings, pastures and shrubbery around settled areas, dooryards, gardens and plantations; in Panama shows affinity for vicinity of water, although this not the case in Colombia. Sea-level to c. 1000 m; in Colombia occasionally to 1400 m, rarely to 2100 m.

Food and Feeding. Of eight stomachs examined, six contained only vegetable matter and two contained both vegetable and animal matter; contents included orthopterans, beetles (Coleoptera), fruit and seeds. Recorded as eating more than 22 species of fruit (72% of 170 feeding records), including those of melastomes (30% of all fruit eaten), especially *Miconia* berries, *Cecropia* (27%) and *Ficus* (19%). Occurs in pairs, in families, and in noisy, conspicuous groups of up to a half-dozen or more individuals, which spend most of the time in fussing and calling from thickets and shrubbery or in visiting small fruiting shrubs and trees. Often calls and flicks wings and tail in agitated manner, especially prior to flight. In W Valle, in Colombia, foraged mostly below 9 m (median height c. 7·5 m) but regularly went to tops of 25-m trees for fruit. Normally perched on twig or branch to take fruit or berries, which were swallowed whole, and perched on and pecked pieces from large fruits such as bananas, *Cecropia* catkins. Rarely took berries by sallying, but about half of 49 observations of insect-catching involved short sallies to air. Also peered and picked insects off foliage, grass, ferns and other substrates. Sometimes insect-searching was acrobatic, involving hanging from leaves or twigs.

Breeding. Season Feb to mid-May in Panama; in Colombia, nesting reported Dec through mid-Apr in W Valle del Cauca, and eleven breeding-condition birds Feb–May in NW; fledged young with adult in early Mar in SW Ecuador (Tambo Negro, in Loja). Nest a compact open cup of leaves and plant fibres, often with leaves and lichens on outside, placed 2–5 m up in bush or tree. Clutch 2 eggs, infrequently 3, blue or greenish-blue marked with black, brown or lavender, sometimes in wreath around large end; in captivity, female alone incubates, period 11–14 days, chicks fed by both adults, and nestling period 12–14 days. Immature males in female-like plumage may breed.

Movements. Resident over most of range, perhaps either scarce or a seasonal visitor on Pacific slope of Canal Zone region of Panama.

Status and Conservation. Not assessed. Usually treated as conspecific with *R. flammigerus*. Locally common to uncommon. Occurs sparingly in Caribbean W Panama, progressively more numerous to E; common and conspicuous in Darién (E Panama), Chocó-Pacific region of Colombia and S into Ecuador. Sightings in Tumbes Reserved Zone, in NW Peru. Found in many protected areas and is particularly numerous in second growth, disturbed and settled areas that are not formally protected. Has profited from partial deforestation and is almost certainly much more numerous and widespread now than formerly. No near-term risks are associated with this species.

Genus *THRAUPIS* Boie, 1826

65. Blue-grey Tanager

Thraupis episcopus

French: Tangara évêque **German**: Bischofstangare **Spanish**: Tangara Azuleja
Other common names: Blue Tanager (when treated as conspecific with *T. sayaca*)

Taxonomy. *Tanagra Episcopus* Linnaeus, 1766, probably Cayenne, French Guiana.
Formerly known as *T. virens*, but present name (of same date) was formally awarded priority. Recent molecular-genetic data do not support monophyly of genus as currently constituted: six (including present species) of eight species sampled embedded with *Tangara*, a finding that makes genus *Tangara* paraphyletic. This species may form a superspecies with *T. sayaca* and *T. glaucocolpa*; replaced by former S of Amazonia. Sometimes considered conspecific with one or both of those, but believed to differ vocally from *T. sayaca* and differs markedly from *T. glaucocolpa* in plumage, voice and habitat; extent, if any, to which race *boliviana* of *T. sayaca* overlaps with present species, with which it shares some plumage features (e.g. white on shoulder), in N Bolivia requires investigation. Some geographical variation within present species is significant, but several races only slightly different and seem barely worthy of recognition; review of the various races seems warranted. Race *ehrenreichi* long treated as synonymous with *coelestis* but now known to be quite distinct; instead, *mediana* might prove to be a junior synonym of *ehrenreichi*. Fourteen subspecies provisionally recognized.
Subspecies and Distribution.
T. e. cana (Swainson, 1834) – SE Mexico (from extreme SE San Luis Potosí) S through Central America, including Pearl Is (off S Panama), to Colombia W of E Andes, Caribbean coast and N Venezuela (E to Sucre and Monagas).
T. e. caesitia Wetmore, 1959 – I Escudo de Veraguas (Bocas del Toro), off NW Panama.
T. e. cumatilis Wetmore, 1957 – Coiba I, off SW Panama.
T. e. nesophila Riley, 1912 – extreme NE Colombia, S & E Venezuela, and Trinidad.
T. e. berlepschi (de Dalmas, 1900) – Tobago.
T. e. quaesita Bangs & Noble, 1918 – SW Colombia (W Nariño) S on Pacific slope to NW Peru.
T. e. leucoptera (P. L. Sclater, 1886) – E slope of Andes in Colombia (Cundinamarca and Meta).
T. e. mediana J. T. Zimmer, 1944 – E Colombia, extreme S Venezuela (S Amazonas, S Bolívar) and N Brazil (E to R Jamundá, and S of Amazon between R Madeira and Tapajós) S to N Bolivia.
T. e. coelestis (Spix, 1825) – SE Colombia, W Brazil (E to R Negro and R Madeira) and NE Ecuador S to C Peru.
T. e. ehrenreichi Reichenow, 1915 – R Purús (NW Brazil).
T. e. episcopus (Linnaeus, 1766) – the Guianas, and N Brazil E of R Jamundá to NW Maranhão, and S to SE Pará and N Mato Grosso.
T. e. caerulea J. T. Zimmer, 1929 – SE Ecuador and N Peru (S to Huánuco).
T. e. major (Berlepsch & Stolzmann, 1896) – Chanchamayo Valley, in C Peru.
T. e. urubambae J. T. Zimmer, 1944 – Urubamba Valley and Amazonian drainage, in SE Peru.

Descriptive notes. 16 cm; 27–45 g. A pale grey and blue tanager with rather short, stout bill. Nominate race has entire head and underparts pale grey with variable blue to glaucous wash, upperparts slightly darker bluish-grey and contrasting with paler head; central tail feathers dull blue, outer feathers with progressively less blue, outermost pair edged blue; upperwing-coverts dark bluish with paler whitish edges, marginal and lesser coverts white; flight-feathers dusky, edged bright blue to turquoise-blue; iris blackish-brown; bill mostly dusky black, narrow base of upper mandible and all except tip of lower mandible blue-grey; legs horn-grey. Sexes similar. Immature is much duller than adult, often lacks contrast between head and back, and has shoulders and wing-coverts greyish, flight-feathers with dull greenish-aqua edgings. Races differ mainly in relative amounts of blue and grey shading in plumage, also in colour of upperwing-coverts, those in N & W of range having coverts pale blue to dark cobalt-blue, races in W & C Amazonia and upper Orinoco region having shoulders white to bluish-white and often a white wingbar (white tips of greater coverts) and prominent blue edging on tail: *cana* has ultramarine-blue lesser wing-coverts (usually hidden), dusky median coverts broadly edged dull blue, dusky greater coverts edged pale blue, primary coverts dark blue, flight-feathers prominently edged bright blue, outer half of each tertial feather dull blue, female similar but slightly duller, with edging on flight-feathers lighter blue; *caesitia* is like previous but darker, particularly below, where uniform from throat to undertail-coverts except for darker sides; *cumatilis* is slightly smaller than last, like *cana* but sides and flanks darker blue, underwing-coverts (especially outer ones) darker; *quaesita* is very like *cana*, but male has greater wing-coverts, primary coverts, and edging on flight-feathers and tertials bluish-green (not blue), female has wing-covert and primary edgings duller blue; *nesophila* has lesser and median coverts concolorous with rest of folded wing; *berlepschi* is brighter overall, with darker blue on rump and lesser wing-coverts; *coelestis* has head, mantle, back, rump and underparts slightly more bluish-grey than others, uppertail-coverts pale silvery blue, tail dull blue with dusky outermost feathers narrowly to broadly edged blue, lesser and median wing-coverts white, greater coverts dull cerulean-blue with prominent white tips (forming white wingbar), primary coverts dark blue, flight-feathers dusky, edged blue, tertials with outer half of feather dull blue and rounded tip whitish, female similar to male but greater coverts brighter blue and flight-feather edgings paler (brighter) blue; *ehrenreichi* has back richer blue than in previous, with crown and rump similar in tone to back rather than paler, edgings of flight-feathers and tail richer blue, white on wing-coverts slightly greyish, whitish edging less extensive on greater coverts; *leucoptera* has shoulder and lesser and median wing-coverts white, somewhat suffused or mixed greyish-blue, greater coverts with only faint whitish tips (no obvious wingbar), both sexes with flight-feather edgings lighter blue; *mediana* closely resembles previous, including whitish shoulder and lesser and median wing-coverts somewhat mixed with blue-grey but differs in both sexes having the greater wing coverts prominently edged white and with the flight-feathers and tail prominently edged blue (similar to *coelestis* and darker than *leucoptera*); *caerulea* has lesser and median wing-coverts white, greater coverts tipped white, is closest to *coelestis* and *major* and of same size, but purer blue than either; *major* is similar to previous, but paler; *urubambae* is very like last, but top of head paler and duller, and wingbar on average not so clearly white. Voice. Song, by both sexes (apparently briefer and weaker by female), a complex series of squeaky and twittering notes, pattern individually and perhaps geographically variable, but typically mixed with strained "tsuee" and "tsuup" notes; sometimes two birds, or mated partners, sing simultaneously, resulting in a jumble of notes; regional dialects reported, but in all areas song rather similar to that of *T. palmarum*. Commonest calls a rising "seeeee" and a dry, strained "tsuup", sometimes followed by a few twittery or squeaky notes.
Habitat. Broad spectrum of essentially non-forest habitats, including all kinds of settled areas, plantations, city parks, gardens, young to old second growth, forest borders, savannas with scattered trees, waste areas and margins of rivers and lakes in dry to humid regions; everywhere thrives in man-altered habitats and, in addition to using crevices in building as nest-sites, sometimes roosts in crevices or beams in building. Rare or absent from arid regions in Central America, and partly to mostly replaced by *T. glaucocolpa* in arid zones along Caribbean coast of Colombia and Venezuela. In region of overlap, race *caerulea* occurs upslope of race *coelestis*, the two intergrading in the upper Amazonian zone. Sea-level to c. 2700 m, mostly below c. 1800 m; locally to 2000 m in Urubamba Valley of Peru.
Food and Feeding. Mostly fruits and arthropods; also nectar. Eleven stomachs contained only vegetable matter; contents of other stomachs were mistletoe berries (Loranthaceae), termites (Isoptera), spiders (Araneae), and caterpillars. In Trinidad study, fed on 21 species of fruit, especially *Didymopanax morototoni* in Araliaceae (23% of all observations of fruit-eating), *Cecropia* (18%) and *Miconia* (12%). Everywhere found in pairs, and in some areas gathers in small loosely associated groups when not breeding, and may roost in larger groups; also briefly joins mixed-species flocks, and readily visits fruiting trees with other species. Noisy and conspicuous. Foraging behaviour versatile, as it peers head down along branches, scans foliage, sallies clumsily to air, takes variety nectar from flowers. In Trinidad, 82% of observed foraging attempts were at 8 m or higher, only 6% below 3 m; 53% of records were of fruit-eating, 37% of insect-seeking, and 10% at flowers. Took small fruits and berries while perched, but clung to larger fruits and pecked out pieces of fruit. Searches for insects by moving quickly through foliage and reaching up to undersurfaces of leaves, stretching and peering at tops of leaves, or lunging to snap prey. Also inspects undersides of branches and twigs by leaning down diagonally and fluttering or lunging to pursue escaping prey, and may sally short distances upwards to air for flying insects. In Trinidad, 56% of insects were obtained on foliage, 17% on branches and twigs, 11% on flowers and seedheads, and 16% in aerial sallies.
Breeding. Season mostly Feb–Jul in Middle America, Jan–Jul in Panama; more or less all months in N South America from Colombia E to Suriname, and in all months except Sept in Trinidad. Usually monogamous; one reported case of bigamy in Costa Rica. Nest built by both sexes, a thick deep cup of rootlets, moss, grass, ferns, leaves and other fine material, mostly 3–20 m up, but occasionally on or almost on ground or as high as 30 m above it, usually well hidden in leafy branch fork, base of palm frond, crevice in building, even in nest of other species such as thornbird (*Phacellodomus*); often pilfers material from unfinished or even occupied nests of other species, including other tanagers, euphonias and tyrant-flycatchers (Tyrannidae). Clutch 1–3 eggs, usually 2, whitish to greyish-green with brown or darker markings; incubation by female, period 12–14 days; chicks fed by both sexes, nestling period 17–18 days; in Costa Rica, one male and two females attended a nest with 4 eggs, both females incubated (dominant female for 77% of time), and all three adults fed young.
Movements. Resident. Some local movements in response to changing fruit abundance may take place.
Status and Conservation. Not globally threatened. Widespread and abundant. Perhaps the most familiar of all tanagers to rural and urban inhabitants alike, and one of the most familiar birds in settled areas in N Neotropics. In Colombia, expanded its range upwards in early 1980s, onto Sabana de Bogotá at 2600 m, where now numerous. Found in hundreds of parks and protected sites throughout its large range. Utilizes a variety of second-growth and disturbed habitats, in both urban and rural areas, which has permitted it to expand its range and increase its numbers almost throughout its range. Known to cause some damage locally to papaya (*Carica papaya*) and other fruits in gardens.
Bibliography. Allen (1905), Anon. 66. Sayaca Tanager

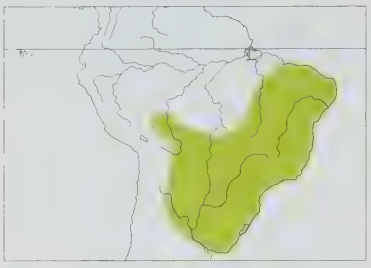
Thraupis sayaca

French: Tangara sayaca **German**: Sayacatangare **Spanish**: Tangara Sayaca
Other common names: Blue Tanager (when treated as conspecific with *T. episcopus*)

Taxonomy. *Tanagra Sayaca* Linnaeus, 1766, possibly Pernambuco, Brazil.
Recent molecular-genetic data do not support monophyly of genus as currently constituted: six (including present species) of eight species sampled embedded with *Tangara*, a finding that makes genus *Tangara* paraphyletic. This species may form a superspecies with *T. episcopus* and *T. glaucocolpa*; replaces former S of Amazonia. Sometimes considered conspecific with one or both of these; reported vocal differences from *T. episcopus* require confirmation; differs markedly from

On following pages: 67. Glaucous Tanager (*Thraupis glaucocolpa*); 68. Azure-shouldered Tanager (*Thraupis cyanoptera*); 69. Golden-chevroned Tanager (*Thraupis ornata*); 70. Yellow-winged Tanager (*Thraupis abbas*); 71. Palm Tanager (*Thraupis palmarum*); 72. Blue-capped Tanager (*Thraupis cyanocephala*); 73. Blue-and-yellow Tanager (*Thraupis bonariensis*).



T. glaucocolpa in plumage, voice and habitat. Race *boliviana* could belong with *T. episcopus*, with which it shares some plumage features (e.g. white on shoulder), but in several other ways is closer to present species; extent, if any, to which this race overlaps with *T. episcopus* in N Bolivia requires investigation. Review of taxonomic status of both groups seems to be warranted. Three subspecies recognized.

Subspecies and Distribution.

T. s. boliviana J. Bond & Meyer de Schauensee, 1941 – N Bolivia.

T. s. obscura Naumburg, 1924 – C & S Bolivia S to W Argentina (S to Tucumán, Córdoba and Santa Fe).

T. s. sayaca (Linnaeus, 1766) – E & S Brazil (Mato Grosso E to Maranhão and Ceará, S to Rio Grande do Sul), Paraguay, NE Argentina (S to Buenos Aires) and Uruguay.

Descriptive notes. 16–17 cm; c. 28–34 g. A pale grey and blue tanager with rather short, fairly thick bill. Nominate race has head and upperparts uniformly dull grey, slightly tinged bluish (no contrast between head and back), throat and breast similar or very slightly paler and gradually fading to dull greyish-white on belly and almost white on undertail-coverts; lesser upperwing-coverts blue (often hidden), median coverts dusky, edged and tipped dull greenish-blue, greater coverts dusky, rather narrowly edged and tipped dull greenish-blue; primary coverts dusky, broadly tipped dull greenish-blue, flight-feathers dusky, edged greenish-blue, tertials greenish-blue with dusky to dusky bluish-green inner webs; tail dusky, tinged and faintly edged greenish-blue; iris dark brown; bill dusky grey, basal half paler blue-grey; legs horn-grey. Differs from *T. episcopus* mainly in slightly greyer plumage, with always grey (not white) lesser and median wing-coverts, and fringing on flight-feathers and tail more turquoise. Sexes similar. Immature is duller, darker and dingier than adult, and nearly identical to immature *T. episcopus* (separation even in hand problematic), both having greater wing-coverts tinged greenish-blue, dusky primary coverts, and distinct dull greenish-aqua edgings on flight-feathers. Race *boliviana* has lesser and median wing-coverts whitish, broadly edged blue-grey, and head slightly paler than back (plumage thus towards *T. episcopus*), but with greenish-blue wing edgings; *obscura* is much like nominate, but slightly darker. Voice. Song a high, squeaky and variable series of short, choppy phrases; songs complex, and may vary individually and geographically. Calls include sharp "chup" and higher "tzit". Vocalizations much like those of *T. episcopus*.

Habitat. Wide range of dry to humid and mostly open or semi-open habitats, including light woodland, savanna with scattered trees, second growth, scrubby vegetation, trees along river margins, hedgerows, cultivated areas, parks, gardens and urban areas; less numerous in humid forest borders and upper canopy of forest. In SE Brazil roosts among leafy foliage in both quiet areas and noisy, high-traffic sites with human and vehicular traffic nearby. Lowlands to c. 1000 m, locally higher; to c. 3200 m (recorded to 3600 m) in Bolivian Andes, and common to 3000 m in Argentina.

Food and Feeding. Fruits, seeds, also buds and parts of tender leaves; some arthropods. Recording as eating 36 species of fruit in SE Brazil, and reported as eating fruits of *Allophyllus edulis* in Paraguay; feeds also on many commercially grown fruits, such as oranges, papayas (*Carica papaya*), palm fruits and figs (*Ficus*). Of 20 stomachs examined, twelve contained only vegetable matter and one only animal matter, and seven contained both; contents included fruit pulp, seeds of *Cecropia*, *Ficus* and *Schinus*, and also hymenopterans. Occurs in pairs when breeding, but at other times usually in groups of three or four individuals or up to several dozen, which may roost, loaf or gather together at fruiting trees; joins groups of other birds at fruiting trees, and sometimes found with mixed-species flocks. Forages mostly in upper part of trees, but regularly descends lower to fruiting trees and shrubs. Hops rapidly in foliage, sallies to air for insects, and inspects flowerheads; behaviour much as that of *T. episcopus*.

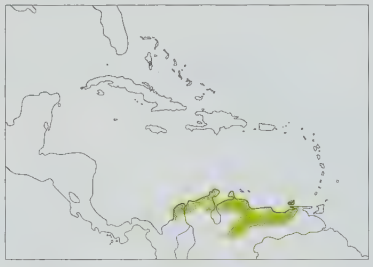
Breeding. Breeding dates mainly Oct–Dec in SC Brazil (Minas Gerais and Mato Grosso) and Paraguay, more widely scattered elsewhere, e.g. Sept–Jan and Apr in Rio de Janeiro and Sept–Feb in Rio Grande do Sul, and Nov in Bolivia; single-brooded at least in Paraguay. Probably monogamous, as partners roost close together on same branch, female usually arriving first. Nest built by female, apparently accompanied by male, a compact cup woven with grass, flower stems, rootlets and moss, sometimes covered with lichens, and hidden in thick foliage 1·5–9 m up in fork of outer limb of tree, frequently an isolated tree near habitation; in Paraguay nesting site often reused from one year to the next. Clutch 2 eggs, rarely 3, varying from yellowish-white to grey to greenish, heavily or lightly marked with shades of brown; incubation by female, period 12–14 days; chicks fed by both adults, leave nest within 20 days; juveniles may remain with adults for considerable length of time after fledging. Nests sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*).

Movements. Partially migratory in S Brazil (Rio Grande do Sul) and in Uruguay, Paraguay and most or all of Argentina; large numbers of migrants spend winter months in NE Bolivia (vicinity of Noel Kempff Mercado National Park) and, at least during Jun–Sept, are regularly seen in loose flocks. Undocumented sight records of this species in SE Peru could, if verified, refer to migratory race *obscura*.

Status and Conservation. Not globally threatened. Widespread and common to locally abundant. Occurs in many protected areas and utilizes a wide range of second-growth and disturbed habitats, both urban and rural, which has allowed it to expand and increase in numbers almost throughout its range. Can become a pest in commercial fruit orchards.

Bibliography. Allen (1891), Belton (1985), Chubb (1910), Contreras (1979a), Descourtilz (1852), Eisentraut (1935), Erickson & Mumford (1976), Euler (1867), de Figueirido & Fernando (2003), Fjeldsa & Krabbe (1990), Guix & Ruiz (1998), Hilty (2009b), Isler & Isler (1999), McCarthy (2006), Meyer de Schauensee (1966, 1970a), Mitchell (1957), Narosky & Di Giacomo (1993), Naumburg (1924), Niethammer (1956), Ogilvie-Grant (1912), Oniki & Willis (2002), Pacheco *et al.* (2007), Parker & Goerck (1997), de la Peña & Rumboll (1998), Ridgely & Tudor (1989, 2009), Ruschi (1979, 1981), Sazima (2008), Sazima & Sazima (2007), Schäfer & Phelps (1954), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sedano & Burns (2010), Short (1975), Sick (1993), Smyth (1928), Snethlage & Schreiner (1929), Souza (2002), Voss & Sander (1980, 1981), Wetmore (1926), Willis & Oniki (2002).

67. Glaucous Tanager



Thraupis glaucocolpa

French: Tangara glauque **German**: Blauflecktangare **Spanish**: Tangara Glauca

Taxonomy. *Th.*[*raupis*] *Glaucocolpa* Cabanis, 1851, Caracas, Venezuela.

Recent molecular-genetic data do not support monophyly of genus as currently constituted: six of eight species sampled (present species not yet analysed) embedded with *Tangara*, a finding that makes genus *Tangara* paraphyletic. This species may form a superspecies with *T. episcopus* and *T. sayaca*. Sometimes considered conspecific with one or both of those, but differs markedly in plumage, voice and habitat. Monotypic.

Distribution. N Colombia (from N Bolívar and Atlántico) E across arid Caribbean coast of Venezuela (to Sucre, and inland in *llanos* S to Barinas, Apure, Guárico and N Anzoátegui); also Margarita I.

Descriptive notes. 16 cm; c. 31–37 g. Has head and upperparts dull smoky grey with greenish tinge (no contrast between head and back); central tail feathers dull greenish-grey, outer feathers dingy dusky grey, edged dull greenish; lesser upperwing-coverts light greenish-blue (often partly hidden), contrasting with duller median and greater coverts, which are greyish, tinged pale blue; primary coverts dusky, edged pale greenish-blue (looking blackish at distance), forming small but prominent spot contrasting sharply with flight-feathers, which are dusky, with basal half of primaries and all of secondaries strongly edged pale aquamarine; tertials dusky, outer half of each feather dull pale aquamarine (dull pale greenish-blue); throat smoky grey (like crown, but paler), underparts pale grey with strong turquoise-blue tinge, belly and undertail-coverts contrastingly white; underwing-coverts white; iris dark brown; bill dusky grey; legs grey. Sexes similar. Immature is like adult, but duller, underparts tinged buff. Voice. Song distinctive, a pulsating series of remarkably high-pitched notes that swell in volume as song progresses, "e-e-e-ee-ee-eee-eee-see-séé-séé-séé", infrequently heard, although more vocal at beginning of rainy season (May–Jun) in *llanos* of Venezuela. Infrequently heard call a high, thin, almost sweet "sweééeeeee", descending at end, singly at intervals of c. 10 seconds or so.

Habitat. Dry deciduous woodland, dry scrub and thorny vegetation, trees along streams, plantations, and gardens near coast. Local in *llanos*, where found mostly in groves of large trees, especially around ranch buildings. In E Falcón (Venezuela), especially during breeding (May–Jul), occurs much more in taller vegetation and in more humid sites (e.g. along streams) than in low, dry scrub. To 800 m.

Food and Feeding. Fruit and insects. Single individuals or pairs stay mostly well up in trees; also sometimes in small groups of 3–5 individuals. Forages for insects and fruit in canopy and upper levels. Occasionally visits feeding trays for cooked rice, e.g. at Hato Cedral (Apure), in W Venezuela. Overall much like *T. episcopus*, but generally less sociable, less conspicuous.

Breeding. Nest records in Apr–Jul (Anzoátegui) and Aug (Guárico) in Venezuela; three breeding-condition birds Apr–Jul in Colombia (César Valley). May usurp nests of thornbirds (*Phacellodomus*), or steal material from *Coereba flaveola* (and perhaps other species) for nesting. No other information available.

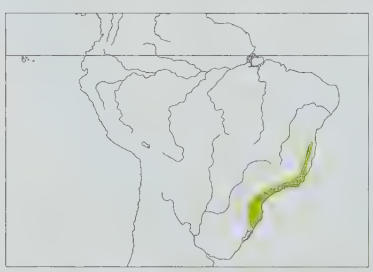
Movements. In E Falcón (Venezuela) numbers increase dramatically during May–Jul/Aug, remaining high perhaps until Oct or Nov. This local migratory movement (probably originating from larger geographical area that includes variety of moist and even humid habitats) concentrates population in desert scrub and acacia (*Acacia*) woodland and dry forest during rainy season. Similar movements may occur in Colombia, with possible seasonal occurrence of birds in humid areas (e.g. Serranía de Quinchas, in W Boyacá).

Status and Conservation. Not globally threatened. Generally uncommon, and found at low density. Less numerous and much less widespread than *T. episcopus*. Occurs in a few protected areas, including Henri Pittier, Morrocoy, Médanos de Coro and Juan Crisóstomo Falcón National Parks (Venezuela) and Santuario de Fauna y Flora los Flamencos (Colombia). Extensive suitable habitat is available to this species also in unprotected areas, including ranchland in W *llanos* region of Venezuela, and these areas should provide a buffer against potential threats, despite the species' relatively small population.

Bibliography. Friedmann & Smith (1950), Hellmayr (1936), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee (1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1950, 1963), Remsen *et al.* (2010), Ridgely & Tudor (1989), Salaman *et al.* (2008), Schäfer & Phelps (1954), Sedano & Burns (2010), Thomas (1979).

68. Azure-shouldered Tanager

Thraupis cyanoptera



French: Tangara à épaulettes bleues **Spanish**: Tangara Cianóptera

German: Violettschultertangare

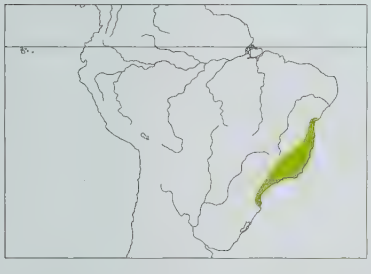
Taxonomy. *Saltator cyanopterus* Vieillot, 1817, Rio de Janeiro, Brazil.

Recent molecular-genetic data do not support monophyly of genus as currently constituted: six (including present species) of eight species sampled embedded with *Tangara*, a finding that makes genus *Tangara* paraphyletic. Monotypic.

Distribution. Coastal SE Brazil from SE Bahia, Espírito Santo and E Minas Gerais S, mostly on coastal slopes of Serra do Mar, to N Rio Grande do Sul.

Descriptive notes. 18 cm; 41–46 g. Fairly large, stout-billed tanager with bluish plumage. Has lores dusky, otherwise head and upperparts uniformly grey-blue (more blue than grey), top of crown more bluish, and becoming bright blue on rump, uppertail-coverts and tail; marginal and lesser upperwing-coverts deep shining violet-blue, greater coverts dusky with broad light turquoise-blue edges, primary coverts and flight-feathers dusky, both broadly edged light turquoise-blue; throat and underparts paler grey-blue than above, with contrasting greenish tinge on flanks; iris dark brown; bill blackish above, contrasting blue-grey below; legs dark horn-grey. Sexes similar. Immature is similar to adult, but duller. Voice. Song rather unlike those of congeners, starts with a soft jumble of notes and ends with several clear melodic notes, e.g. "jittle-jittle-jittle, jeeeyr-jurr", given quickly and frequently repeated two or three times; can also be transcribed as a squeaky "look heeere, right heeere, drink-drink-jrrr", complex at first, slower and musical at end. Call a thin, strained "sweee", much like that of others in genus; also various squeaky notes.

Habitat. Humid montane forest, open woodland, second growth and borders; generally much more of a forest-dwelling species than most congeners. Found mostly on seaward slopes of Serra do Mar. Lowlands to 1600 m, mostly below 1200 m.



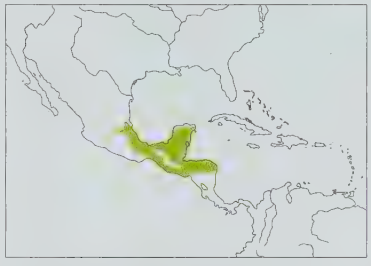
Food and Feeding. Observed to eat fruit of melastomes and palms (*Livistona*). Limited information somewhat conflicting. Foraging and feeding behaviour much like that of *T. sayaca*. Reported as foraging with mixed-species flocks in Espírito Santo, although near Rio de Janeiro was not found with mixed flocks; in Rio Grande do Sul was recorded only during austral winter and seen in single-species flocks of 15–20 individuals. Forages in tall trees; in Espírito Santo, searched moss on large limbs and branches. Seen to be aggressive towards *T. sayaca*.
Breeding. Reported as breeding in Oct in Espírito Santo. Clutch 2 eggs, pale blue, sparingly marked all over with small purplish-black spots. No other information.
Movements. Not well documented. Probably resident; may be migratory in extreme S of range.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Uncommon to locally fairly common. Reports of this species at localities W to Paraguay believed to refer to misidentified *T. sayaca*. Occurs mainly inside humid forest and is less able to utilize forest edge and second growth than are most others in the genus, a factor that has contributed to its severe range contraction and fragmentation following deforestation. Believed to be in decline. Found in a number of protected areas, including Itatiaia, Tijuca, Serra dos Órgãos and Serra da Bocaina National Parks, Serra do Mar, Desengaño and Intervales State Parks, and Sooretama Biological Reserve. Possibly occurs in only relatively few areas outside protected sites.
Bibliography. Anon. (2010a), Belton (1985), Butchart & Stattersfield (2004), Davis (1945b, 1946), Diamond & Lovejoy (1985), Hamilton (1871), Holt (1928), Isler & Isler (1999), Ogilvie-Grant (1912), de la Peña & Rumboll (1998), Ridgely & Tudor (1989, 2009), Sedano & Burns (2010), Sick (1985, 1993), Souza (2002), Stattersfield & Capper (2000).

69. Golden-chevroned Tanager

Thraupis ornata

French: Tangara orné **German**: Schmucktangare **Spanish**: Tangara Adornada
Other common names: Archbishop's Tanager

Taxonomy. *Tanagra ornata* Sparrman, 1789, "in India Orientali"; error = Rio de Janeiro, Brazil.
Recent molecular-genetic data do not support monophyly of genus as currently constituted: six (including present species) of eight species sampled embedded with *Tangara*, a finding that makes genus *Tangara* paraphyletic. Monotypic.
Distribution. Coastal SE Brazil from SE Bahia S, extending inland to E Minas Gerais, to E Santa Catarina.



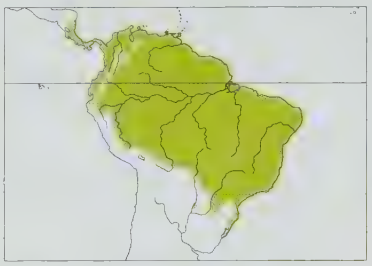
Descriptive notes. 18 cm; one female 33 g. Fairly large tanager with bill thinner than in congeners. Male has loral area dusky, otherwise head, neck and upper breast shining cadet-blue, brightest on crown, paler and tinged grey on throat; upperparts dingy dark blackish-olive, tail dusky with pale greenish-yellow to turquoise-blue fringes; bend of wing and lesser upperwing-coverts bright blue (usually concealed), median coverts bright golden-yellow (forming conspicuous patch), greater coverts dusky, edged and broadly tipped olive-green; primary coverts dusky with bluish outer webs, flight-feathers and tertials blackish, edged pale greenish-yellow to turquoise-blue; centre of breast dull blue to greyish-blue with violet tinge, centre of belly greyish, tinged bluish-green, undertail-coverts whitish with darker, smoky grey centres; iris dark brown; bill black, slightly paler base; legs blackish. Female is similar to male, but duller and greyer above and below. Immature is duller than adult, almost devoid of blue. Voice. Song a series of up to c. 9 squeaky notes mixed with squeezed and slurred notes, much like that of congeners. Reportedly only male sings and songs may differ among individuals. Call a high, rising "seeee" much like that of others of genus.
Habitat. Variety of wooded and semi-open habitats, including forest edge, shrubby clearings, gardens, settled areas and canopy of humid forest. Lowlands to 1750 m; more numerous in mountain regions than in lowlands.
Food and Feeding. Fruit and arthropods. Reported as eating fruits of *Livistona* palms, figs (*Ficus*) and bananas. Occurs in pairs when breeding, otherwise gathers in loosely associated groups up to c. 25 or more individuals; also joins with mixed-species flocks and, especially around fruiting trees, often aggressive towards both conspecifics and other species. Forages in restless active manner, mostly in canopy and treetops, occasionally much lower, even on the ground for fallen fruit. Searches for insects in lichens and moss by hopping along large limbs, and also peers at foliage and twigs. Regularly visits feeders.
Breeding. Recorded in Oct and Nov. Nest cup-shaped, usually 1·5–9 m up in foliage of outer branch of tree or bush, sometimes among epiphytic bromeliads, also seen to carry nesting material into bromeliads at least 15 m up; also reported nesting in old nest of hornero (*Furnarius*); often nests close to dwelling and in vicinity of humans. Clutch 3 eggs, white or reddish-white marked with brownish-black, purplish-grey or deep purplish-brown; female alone believed to incubate. No other information.
Movements. Partially migratory, those in S portion of range moving N and those at higher elevations in mountains of N part of range moving downslope during austral winter. Numbers decrease in mountains of Espírito Santo in winter months.
Status and Conservation. Not globally threatened. Locally fairly common. Found in numerous protected areas in SE Brazil, including Serra da Bocaina, Itatiaia, Tijuca and Serra dos Órgãos National Parks, Serra do Mar and Intervales State Parks, and Sooretama Biological Reserve. Outside parks and reserves, relatively little intact habitat exists within this species' historic range, but it is fairly common locally in numerous protected sites. In addition to mature forest, it utilizes a variety of second growth, edge and settled and urban areas with trees, which should ensure its continued survival.
Bibliography. Davis (1945a, 1946), Descourtilz (1852), Diamond & Lovejoy (1985), Goeldi (1894), Hamilton (1871), Holt (1928), Isler & Isler (1999), Mitchell (1957), Nehrkorn (1899), Ogilvie-Grant (1912), Parker & Goerck (1997), Ridgely & Tudor (1989, 2009), Sedano & Burns (2010), Sick (1985, 1993), Souza (2002).

70. Yellow-winged Tanager

Thraupis abbas

French: Tangara à miroir jaune **German**: Abttangare **Spanish**: Tangara Aliamarilla
Other common names: Abbot's Tanager

Taxonomy. *Tanagra Abbas* W. Deppe, 1830, Jalapa, Veracruz, Mexico.
Recent molecular-genetic data do not support the monophyly of genus as currently constituted, with six of eight species sampled embedded with *Tangara*, a finding that makes genus *Tangara* paraphyletic; further research required. Monotypic.
Distribution. E & SE Mexico (from c. 15 km NW of Gómez Farías, in S Tamaulipas, and SE San Luis Potosí, and from Oaxaca) S on Caribbean slope to NC Nicaragua and on Pacific slope to S Honduras (possibly also NW Nicaragua); a published sight record from N Costa Rica.



Descriptive notes. 17 cm; 38–55 g. A rather dull-plumaged tanager with yellow wingband and fairly thick bill. Head and neck campanula-blue (lilac-blue), brightest on crown, narrow black line over bill and lores, throat usually slightly greyer and paler, often with some black on chin; mantle, scapulars and back smoky blue-grey, mottled with dusky, rump buffy olive, uppertail-coverts dull blue-grey, tail black; lesser upperwing-coverts campanula-blue, median coverts more olive with pale blue tinge and concealed dusky bases, greater coverts buffy olive; flight-feathers and tertials deep black (folded wings forming distinctive triangular black area across rear half of body), broad, sharply defined straw-yellow band crossing lower mid-section of primaries (conspicuous at rest and in flight); blue of throat fades to blue-tinged grey on chest and upper breast, becoming dull buffy olive to yellowish-olive on sides, flanks, belly and undertail-coverts; iris dark brown; bill blackish; legs dark grey. Sexes similar. Juvenile has head and upperparts olive, mottled dusky on back, and is mostly greyish below. Voice. Song described as a slightly reedy descending trill, often with 1 or 2 introductory notes, "shee iiiiiiiiiiiiiiiiir", or preceded by 1 or 2 rough notes; also as a high, flat, trill 2–4 seconds long, "che-che-che-che-che...", often preceded by a single note. High, thin, strained calls include "sseeu" and "swee", given from perch or in flight, and other squeaky notes.
Habitat. Moderately dry to humid forest borders, clearings with trees, plantations, parks, gardens and other semi-open areas with scattered trees; not inside forest. Lowlands to c. 1800 m.
Food and Feeding. Insects and fruit; fond of figs (*Ficus*). Lives in pairs when breeding, at other times in pairs or groups up to about ten individuals, occasionally up to 50 or even more. Often attracted to fruiting trees, where typically aggressive and quarrelsome towards other birds and may attempt to drive them away. Often perches high on open bare branches, and may fly off considerable distances to forage or rest. Will hop rather slowly along branches in search of insects; pecks pieces from large fruits, and pecks from areas already opened by other birds. Behaviour much like that of *T. episcopus*.
Breeding. Breeding reported during Feb–Jul from Mexico S to El Salvador. Nest built by both sexes, from small twigs, grass, dry leaves and moss, lined with finer material, placed mostly at middle level, c. 3–18 m up, on horizontal branch of tree with dense foliage, or at base of palm fronds; has been observed to take nesting material to tree cavity in Belize; one Apr nest in Guatemala was 4 m up under roof of metal building and c. 25 m from forest. Clutch 2–3 eggs, pale bluish-grey, thickly spotted with reddish-brown; some feeding of young may be by regurgitation. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common. Range encompasses a number of protected areas, including Palenque, Cañon del Sumidero and Cascadas de Agua Azúl National Parks, and Selva del Ocote, Sian Ka'an and Calakmul Biosphere Reserves (all in Mexico), Tikal National Park (Guatemala), Cockscomb Basin National Park (Belize) and Capiro–Calentura National Park (Honduras); may occur also in one or more parks in Nicaragua. Adapted to a variety of second-growth and disturbed habitats and readily found in many localities outside protected areas. Has benefited from partial deforestation and human settlement and faces no serious near-term threats.
Bibliography. Berrett (1962), Binford (1989), Boyd (2001), Davis (1972), Dickey & van Rossem (1938), Edwards (1972), Edwards & Tashian (1959), Eisenmann (1955), Eisermann & Brooks (2006), Howell & Webb (1995), Isler & Isler (1999), Klaas (1968), Land (1970), Ogilvie-Grant (1912), Rainwater *et al.* (2001), Ridgely & Tudor (1989, 2009), Russell (1964), Sánchez & Campos Ramírez (1988), Sclater & Salvin (1859), Sedano & Burns (2010), Skutch (1954), Smithe (1966), Sutton & Burleigh (1940), Tashian (1953), Wetmore (1941, 1943), Zuñiga & Sandoval (2011).

71. Palm Tanager

Thraupis palmarum

French: Tangara des palmiers **German**: Palmentangare **Spanish**: Tangara Palmera
Other common names: Common Palm Tanager

Taxonomy. *Tanagra palmarum* Wied, 1821, Canavieras, Bahia, Brazil.
Recent molecular-genetic data do not support monophyly of genus as currently constituted: six (including present species) of eight species sampled embedded with *Tangara*, a finding that makes genus *Tangara* paraphyletic. Four subspecies recognized.
Subspecies and Distribution.
T. p. atripennis Todd, 1922 – E Nicaragua S to Colombia W of Andes (including Santa Marta region) and NW Venezuela (Maracaibo region).
T. p. violilavata (Berlepsch & Taczanowski, 1884) – SW Colombia (from Cerro Munchique, in Cauca) S through W Ecuador almost to Peruvian border.
T. p. melanoptera (P. L. Sclater, 1857) – E Colombia, Venezuela (except Maracaibo region), including Margarita I and Patos I, Trinidad, Tobago, the Guianas, and N & C Brazil (N of R Amazon and, S of it, from R Tocantins, in E Pará) S to E Ecuador, E Peru, N Bolivia and C Mato Grosso.
T. p. palmarum (Wied, 1821) – E Brazil (E from R Tocantins, S to Mato Grosso, W Paraná, and NE Rio Grande do Sul), E Paraguay (one record in Alto Paraná) and N Argentina (sight records in Misiones and E Formosa).
Descriptive notes. 17 cm; 27–48 g. Generally drab-looking tanager with glossed plumage, in poor light sometimes appearing featureless. Male nominate race has head creamy olive, forecrown tinged yellowish, upperparts smoky brown, tail dusky brown with olive tinge; upperwing-coverts paler than back and with slight yellowish tinge; primary coverts mostly blackish, flight-feathers blackish (folded wing forms conspicuous dark triangular area on rear half of body), prominent pale olive-yellow wingband (most visible in flight) extending across outer flight-feathers as narrow pale yellowish edging; underparts shining smoky buff with yellowish tinge; iris dark brown; bill black; legs dusky. Female is similar to male, but may be on average slightly more olive. Immature is much like adult, but duller. Races differ mainly in depth of plumage coloration, nominate palest: *melanoptera* is darkest, mainly dark smoky greyish-olive with brownish to yellow tinge, forecrown to mid-crown

strongly tinged yellow, upperwing-coverts buffy yellow-olive (slightly paler than back), dark smoky olive-grey below, slightly paler on lower underparts; *atripennis* is very similar to previous, but yellowish tinge on head contrasts more strongly with hindneck, body plumage slightly paler, and wing blacker, occasional variant of this race is strongly tinged violet throughout, including entire body plumage and wing-coverts; *violilavata* is olive-grey to blue-grey, often with violaceous tinge on breast, lesser wing-coverts glossed bluish (usually concealed), greater coverts cerulean grey, often with buffy olive tinge, flight-feathers slightly duller and less contrasting. VOICE. Song, often from top of palm spike, a rapid unmusical stream of high squeaky, twittering and clear notes with lispy quality, all given at about same speed; overall much like that of *T. episcopus*, but somewhat less musical, and lacks strained "tsuee" notes characteristic of latter's song. Calls include a lispy "seeee?", a downslurred "seeeyou", and rising "wheerst", also various other thin notes and rattles.

Habitat. Wide variety of habitats. Widespread in shrubby clearings, second growth, gallery forest, forest edges, and canopy of humid forest; in fairly dry to humid regions and, as name suggests, often common where palms numerous. Generally more abundant than *T. episcopus* in regions of extensive humid forest and often less numerous in populated and cultivated areas with scattered trees. Also locally numerous in patches of scrubby woodland and gallery-forest borders. Lowlands to c. 1300 m, locally in Andean valleys to 2600 m.

Food and Feeding. About equal amounts of fruit and insect matter, also flower petals. In Trinidad ate 24 species of fruit, especially *Didymopanax* (29% of all records of fruit-eating), *Miconia* (21%) and *Cecropia* (11%), and fed at flowers (9% of records). Of 13 stomachs examined, twelve contained only vegetable matter and one contained both vegetable and animal matter; contents included fruit, pulp, seeds, and chitin fragments. Contents of other stomachs included mistletoe berries (Loranthaceae) and termites (Isoptera). Rather social, occurring in pairs, also often in small, noisy groups, and occasionally up to a dozen gather in bare treetops and at roost; often with mixed-species foraging flocks, and often with *T. episcopus*. Has been reported as roosting in groups of 10–75, presumably somewhat separated, in a tree. Generally forages fairly high up, e.g. in Colombia and Trinidad 80% of all foraging records were above 7·5 m; about half of observations in both areas were of insect-seeking. Foraging behaviour notably versatile. Readily clings to tips of palm fronds, hangs upside-down beneath frond tips, and gleans and sallies for insects. In all areas commonly hangs on to side or underside of large leaves, under palm fronds, beneath *Cecropia* leaves or catkins, and under banana leaves to search for insects. Behaviour much like that of *T. episcopus*, but less of an urban bird and often forages in treetops in forested regions.

Breeding. Breeding reported in Jan–Jun in Panama, Jul–Sept and Dec in Colombia, Jan in Guyana, Dec–Sept in Suriname, Jul in French Guiana, in all months in Trinidad, and Oct– Dec in Brazil (Pará, Rio de Janeiro and Rio Grande do Sul); sometimes multi-brooded, and in Trinidad pairs known to breed up to four times in a season. Nest built by both sexes, in Costa Rica a neat cup of grass, dry leaf strips, palm fibres and similar, placed 6–30 m above ground in palm, leaf cluster, epiphyte, or cavity or crevice, even in building. Clutch 2 eggs, pale bluish, heavily spotted brown and pale lilac; incubation by female alone, period c. 14 days; chicks fed by both adults, nestling period 17–21 days. Nests sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*).

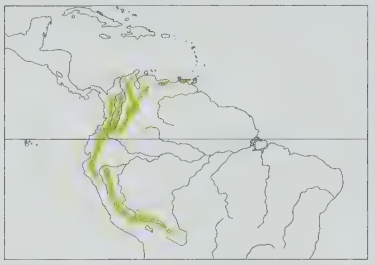
Movements. Resident.

Status and Conservation. Not globally threatened. Common and widespread over much of ample range. Utilizes variety of undisturbed humid forest habitats, as well as second growth and disturbed environments. Readily adapts to human-altered environments, often occurring in close proximity to human settlement, although typically less numerous in settled areas than is *T. episcopus*. Has benefited from partial deforestation and activities of humans. In Colombia, not present on Sabana de Bogotá until some time in 1980s, but now locally common there. This species' ability to use disturbed and settled areas should buffer it against future threats.

Bibliography. Álvarez-Rebolledo *et al.* (2003), Anon. (2000), Belcher & Smooker (1937), Belton (1985), Cavalcanti & Pimentel (1988), Chubb (1921a), Collins (2006), Collins & Araya (1998), Davis (1972), Donegan & Dávalos (1999), ffrench (1991), Friedmann & Smith (1950), Garrigues & Dean (2007), Hartman (1955), Haverschmidt (1948), Haverschmidt & Mees (1994), Herklots (1961), Hilty (1997, 2003), Hilty & Brown (1986), Ingels (1978, 1983), Isler & Isler (1999), Jahn *et al.* (2002), Lamm (1948), Layard (1873), Leck (1975), McCarthy (2006), Meyer de Schauensee (1964, 1966, 1970a), Miller (1947, 1963), Mitchell (1957), Narosky & Di Giacomo (1993), Novaes & Pimentel (1973), Parker & Goerck (1997), Pearson (1971), de la Peña & Rumboll (1998), Phelps (1943), Pinto (1944a, 1944b), Ricklefs (1968, 1976), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schäfer & Phelps (1954), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sclater & Salvin (1879), Sedano & Burns (2010), Sick (1993), Slud (1964), Snow, B.K. & Snow (1971), Snow, D.W. & Snow (1964), Souza (2002), Stiles & Skutch (1989), Strauch (1977), Tostain *et al.* (1992), Voss (1977b), Walker (2001), Wetmore *et al.* (1984), Williams (1922), Willis (1980), Willis & Eisenmann (1979), Young (1929), Zimmer (1944).

72. Blue-capped Tanager

Thraupis cyanocephala



French: Tangara à tête bleue **German**: Gelbschenkeltangare **Spanish**: Tangara Coroniazul
Other common names: Aragua/Blue-bellied Tanager (*olivicyanea*)

Taxonomy. *A.[glaia] cyanocephala* d'Orbigny and Lafresnaye, 1837, Yungas, Bolivia.

Recent molecular-genetic data do not support monophyly of genus as currently constituted: six of eight species sampled embedded with *Tangara*, a finding that makes genus *Tangara* paraphyletic; present species appears to be most closely related to *Anisognathus*, not *Tangara*. This species exhibits considerable geographical variation, especially in N of range; race *olivicyanea* has in the past been regarded as a separate species, but intergrades with others. Eight subspecies recognized.

Subspecies and Distribution.

T. c. margaritae (Chapman, 1912) – Santa Marta Mts, in N Colombia.
T. c. auricrissa (P. L. Sclater, 1856) – Andes of W Venezuela (Trujillo S to Táchira) and adjacent Colombia (Norte de Santander S to Cundinamarca), also Perijá Mts on Colombia–Venezuela border.
T. c. hypophaea (Todd, 1917) – Andes of NW Venezuela (in Lara).
T. c. olivicyanea (Lafresnaye, 1843) – coastal cordillera of N Venezuela (Aragua E to Miranda).
T. c. subcinerea (P. L. Sclater, 1861) – Sucre (except Paria Peninsula) and N Monagas, in NE Venezuela.
T. c. buesingi (Hellmayr & Seilern, 1913) – extreme NE Venezuela (Paria Peninsula); N Trinidad.
T. c. annectens J. T. Zimmer, 1944 – C & W Andes of Colombia.
T. c. cyanocephala (d'Orbigny & Lafresnaye, 1837) – Andes of Ecuador (both slopes) S through Peru (mainly E slope) to N Bolivia.

Descriptive notes. 16 cm; 27–47 g. Medium-sized blue-headed tanager. Nominate race has crown, nape and side of head shining cornflower-blue, lores black, becoming blackish around eye, forming a rather ill-defined small mask; upperparts, including uppertail-coverts, bright yellowish-olive, tail yellowish-olive, much like back; bend of wing bright yellow, upperwing-coverts uniformly yellowish-olive, flight-feathers dusky, broadly edged yellowish-olive, and from below outer web of most of primaries pale yellow (most of underwing yellow, conspicuous in flight), tertials mainly yellowish-olive; throat and underparts dull bluish-grey, thigh bright yellow, undertail-coverts yellow, underwing-coverts bright yellow; iris dark maroon-brown; upper mandible black, paler base, lower mandible blue-grey with dark tip; legs dark grey. Sexes similar. Immature is duller than adult, with less blue on head, and underparts mostly grey. Races differ mainly in tone of plumage coloration: *annectens* is much like nominate, but throat and breast more strongly tinged blue, merging into bluish-grey on lower underparts, flanks dull yellowish-olive; *auricrissa* is very like previous, but underparts slightly darker and more strongly bluish, centre of belly and undertail-coverts brighter yellow; *margaritae* differs from nominate in smaller size and in having blue-tinged throat and chest sharply separated from grey of lower underparts; *hypophaea* is much like nominate, but underparts strongly tinged blue; *olivicyanea* differs in having entire head, neck and almost all of underparts blue, with thigh and undertail-coverts yellowish to greenish-yellow; *buesingi* differs in having only top of head blue, with side of head dusky, and underparts darker grey with grey-flecked whitish malar stripe; *subcinerea* is similar to nominate, but has pale grey malar line much like that of last race. VOICE. Not especially vocal. Song may vary somewhat geographically. In Venezuela a twittery, unmusical jumble of notes somewhat resembling that of *T. episcopus*, e.g. a strained "tsuee-tsuee-tee-ee-ee-seet"; in Peru described as a series of phrases consisting of sharp, squeaky notes, e.g. "swick-it, swick-it-chéw-y...", or "swickity-chew, swickity-chew...", each phrase repeated up to five times; another song in Peru described as "tsee-tsee-tsee, cha cha cha cha..." (up to 10 "cha" notes), the last part like a coarse rattle. Call high insignificant "tsit" notes.

Habitat. Humid, montane forest borders, adjacent overgrown highland pastures with scattered taller trees, and variety of disturbed, even trashy habitats, including patches of second-growth woodland, tree-lined fence rows, and coffee plantations; in landslide areas often in alder (*Alnus*) trees. In most areas found from c. 1500 m to 3000 m, locally as high as 3300 m in Bolivia, and most numerous above c. 1800 m; as low as 800 m in Venezuela and 550 m in Trinidad.

Food and Feeding. Fruit and insects. Feed heavily on fruit; in Cundinamarca (Colombia) often eats berries of *Oreopanax*, *Miconia* and *Myrica*. Of 21 stomachs examined, 19 contained only vegetable matter and two contained both vegetable and animal matter; contents were berries, fruit pulp, seeds and insects. Pairs or groups of up to eight or more follow mixed-species flocks, especially those containing *Tangara* and other tanagers, along forest borders; also wander alone, and gather briefly with other species at fruiting trees. Mostly keeps fairly high in trees, where active, conspicuous and easy to see; sometimes descends low to fruiting shrubs. Also pecks or gleans insects from foliage, and occasionally sallies short distances to air for flying insects.

Breeding. Nest found in Jun in Trinidad; 23 breeding-condition birds during Apr–Sept in Colombia. Trinidad nest a deep cup built 8 m above ground in branch fork of tree at forest edge. Clutch 2 eggs, pale greenish-blue with sepia or blackish markings; in Colombia eggs reported also as cream-coloured with bold purplish-brown or grey markings, more numerous at large end, and in Bolivia as reddish-grey with red-brown markings. No other information.

Movements. Apparently resident.

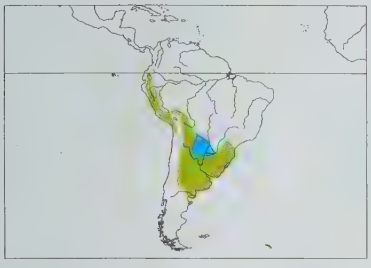
Status and Conservation. Not globally threatened. Common and widespread in disturbed and younger second-growth habitats throughout middle elevations in Andes. Occurs in many protected areas, but also thrives in unprotected areas wherever there is bushy regrowth vegetation. Scarce in canopy and at edges of mature montane forest, but common in partially deforested, degraded and settled areas, where it benefits from human activities.

Bibliography. Anon. (2000), Belcher & Smooker (1937), Clements & Shany (2001), Donegan & Dávalos (1999), ffrench (1991), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Moore *et al.* (1999), Nehrkorn (1899), Ogilvie-Grant (1912), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schäfer & Phelps (1954), Schulenberg (2000b), Schulenberg *et al.* (2007), Taczanowski (1884), Walker (2001), Zimmer (1944).

73. Blue-and-yellow Tanager

Thraupis bonariensis

French: Tangara fourchu **German**: Furchentangare **Spanish**: Tangara Naranjera
Other common names: Darwin's Tanager (*darwinii*)



Taxonomy. *Loxia bonariensis* J. F. Gmelin, 1789, Buenos Aires, Argentina.

Recent molecular-genetic data do not support monophyly of genus as currently constituted: six of eight species sampled embedded with *Tangara*, a finding that makes genus *Tangara* paraphyletic; present species appears to be most closely related to *Pipraeidea and Iridosornis*, not *Tangara*. Geographical variation in plumage substantial; *darwinii* dullest race, sometimes considered a separate species, also differing somewhat in song from others; further study needed. Four subspecies recognized.

Subspecies and Distribution.

T. b. darwinii (Bonaparte, 1838) – Andes of Ecuador (from S Carchi, Imbabura and extreme W Napo S, mainly in C highlands, to Loja), and in Peru S on W slope to N Chile (Tarapacá) and on E slope to Bolivia (La Paz).
T. b. composita J. T. Zimmer, 1944 – C Bolivia (Cochabamba and Santa Cruz).
T. b. schulzei Brodkorb, 1938 – SE Bolivia, extreme W Paraguay and NW Argentina (S to Mendoza, La Pampa, and San Antonio Oeste, in N Río Negro).
T. b. bonariensis (J. F. Gmelin, 1789) – SE Brazil (S São Paulo to Rio Grande do Sul), Uruguay and E Argentina (S to Buenos Aires province).

Descriptive notes. 17 cm; 28–46·5 g. A mostly open-country tanager that becomes much brighter in plumage in S portion of range. Male nominate race has head, neck and throat bright cornflower-blue, narrow line over bill, lores, around eye and chin black (forming small, contrasting mask); mantle, back and scapulars blackish, extending to side of chest and forming partial black collar;

rump bright orange-yellow; upperwing-coverts dusky, all except lowest feather of greater coverts broadly edged blue; flight-feathers dusky, edged blue; tail black, heavily edged blue; chest to mid-breast rich deep yellow-orange, becoming bright yellow on lower underparts; eyes reddish-brown; bill blackish above, lower mandible mostly pale grey, frequently with yellowish-horn tinge; legs dark grey. Female is much duller than male, mainly greyish-brown above, greyer on throat and chest, lower underparts dull buff. Juvenile is mainly dull brownish-grey above and paler below, almost devoid of colour, or with hint of blue on wing. Races differ in size, but mainly in plumage of male: *composita* is similar in size to nominate, male with rich orange of breast extending slightly less onto lower underparts, female has more blue on head; *schulzei* is slightly smaller than previous, male has blue of head darker, is less richly coloured below, orange of breast less deep and less extensive; *darwinii* is distinctive, male head and throat dull blue, lores and ocular area black, back and side of chest olive, rump yellow, longest uppertail-coverts dull olive, wing feathers broadly edged and tipped blue, tail edged and tinged blue, central breast and rest of underparts yellow, duller on belly and undertail-coverts, female notably dull, dingy brownish-olive above, rump tinged buff, head somewhat bluish, all wing feathers edged greyish-blue, underparts buffy olive. Voice. Song (in Argentina) a loud, sweet and remarkably musical but rather repetitive "swéét-sur, swéét-sur, swéét-sur, swéét-sur", occasionally preceded by short trill or single note, and each phrase rising and than falling in pitch; unlike those of congeners (which are squeaky). Dawn song similarly rhythmic, but more complex. Apt to sing a few times, then move to another tree and repeat the performance. Songs far-carrying and generally louder, crisper and cleaner in S of range.

Habitat. Wide range of habitats, from humid and wet cloudforest borders and humid second-growth woodland to parks, gardens, orchards, arid semi-open highlands, dry scrubby hillsides, brushy borders of agricultural fields, and settled and cultivated areas in dry to moist regions; occurs in trees near water in arid areas, and in groves of *Celtis* in Argentine pampas. In general most numerous in dry, scrubby semi-open areas in Andes and in semi-open areas with patches of woodland in more humid areas, such as *pampas* in Argentina. Usually not inside humid forest, but does occur in disturbed woodland in humid areas (e.g. Urubamba Valley below Machu Picchu, in Peru). From sea-level to c. 2550 m; race *darwinii* mostly c. 2000–3000 m, locally higher (recorded to 3600 m), but down to 1000 m in dry inter-Andean valleys, and to sea-level on Pacific coast of Peru.

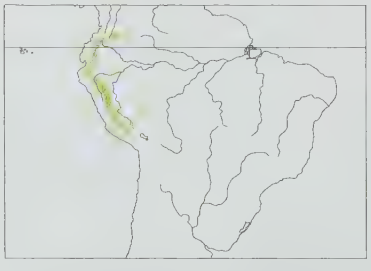
Food and Feeding. Takes both fruit and insects; most often seen in fruiting trees or shrubs, and at cactus fruits, and in settled areas eats a variety of cultivated fruits. Occurs alone, in pairs and, at least during some times of year, in small groups of three or four individuals; often seen at fruiting trees and in flowering trees (e.g. *Inga* in Peru) with other species, but usually not with mixed-species foraging flocks, occurring mainly in semi-open areas where few insectivorous flocks form. Forages at various heights, often rather low, but regularly sits higher, often on exposed perch. Generally conspicuous and familiar wherever it occurs.

Breeding. Breeding dates range from Apr in Peru to Nov–Dec in Bolivia; Mar and Apr in Chile, Dec and Jan in Argentina, and Nov–Jan in Uruguay and Brazil (Rio Grande do Sul); second broods may be attempted. Simple cup-nest in horizontal fork in crown of bush or small tree, often no more than 2 m up. Clutch 2–4 eggs, usually 3 (apparently larger clutches in S latitudes), variable in colour even within same clutch, may be dirty white, pale blue or pale green, thickly marked with dark grey, especially at larger end. No other information.

Movements. S breeders migratory, most moving N out of Argentina during austral winter; possibly migratory also in Uruguay and S Brazil. During non-breeding season, some birds occur farther N, in SE Bolivia, N Argentina and Paraguay.

Status and Conservation. Not globally threatened. Common and widespread over almost all of its extensive range. Has profited from deforestation, settlement and other human activities. In some areas is regarded as a pest, because it frequently damages fruit in orchards.

Bibliography. Alabarce & Lucero (1977), Aplin (1894), Belton (1985), Burns & Naoki (2004), Burns *et al.* (2002, 2003), Chapman (1926), Descourtilz (1852), Di Giacomo (2009), Dinelli (1924), Dunning (1982), Eisentraut (1935), Fjeldså & Krabbe (1990), Friedmann (1927), Isler & Isler (1999), Jaramillo (2003), Johnson & Goodall (1967), Koepcke (1954, 1970), Mason (1985), Narosky & Yzurieta (1987), de la Peña & Rumboll (1998), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Short (1975), Sick (1985, 1993), Taczanowski (1884), Vigil (1973), Walker (2001), Wetmore (1926), Zapata (2000), Zimmer (1930, 1944).



Genus *CALOCHAETES* P. L. Sclater, 1879

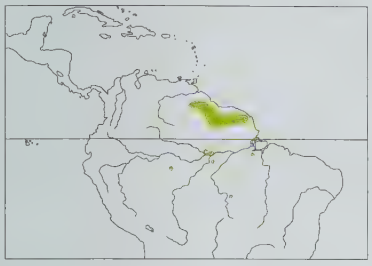
74. Vermilion Tanager

Calochaetes coccineus

French: Tangara carmin **German**: Mennigtangare **Spanish**: Tangara Bermellón

Taxonomy. *Euchaetes coccineus* P. L. Sclater, 1858, River Napo, Ecuador.
Monotypic.
Distribution. E slope of Andes from S Colombia (W Caquetá) S to S Peru (Ayacucho and Cordillera Vilcabamba, in N Cuzco).

Descriptive notes. 15 cm; 42–49 g. Chunky, short-tailed and strikingly patterned, with rather short, thick bill. Has loral area, ocular area, throat and uppermost chest black (forming large bib), also median and greater upperwing-coverts, flight-feathers and tail deep black; entire rest of plumage glistening intense red; iris dark brown; bill black, basal half of lower mandible blue-grey; legs dark horn-grey. Sexes alike. Juvenile apparently undescribed. VOICE. Rather quiet overall. Song (or possibly subsong) may be thin "chip" or "sit" notes followed by short soft rolling trills, e.g. "chip, sip, sit-t-t-t-t-t, chip, sit-t-t-t-t-t", etc. Calls include sharp, high "chip" and "zit" notes that often accelerate into twittering trills, e.g. "chip chip zit-t-t-t-t", which may represent a song; also, when foraging, high, sharp "seek!", and "tsee-seek!".
Habitat. Occupies pre-montane and montane wet forest (cloudforest) and wet forest edges. Found at c. 320–600 m in Colombia, but at 1100–1800 m in Ecuador and 900–1800 m (possibly higher) in Peru.
Food and Feeding. Insects, and fruit, especially *Cecropia* catkins and large fruits of melastomes. One stomach contained *Cecropia* seeds. Found mostly in small groups of 3–5 individuals, occasionally up to eight together; regularly with mixed-species flocks, especially those with *Tangara* and other tanagers. Forages well up in trees, by hopping along mossy branches from interior of tree outwards to foliage and peering from side to side, checking bark, moss and leaves; rarely sallies to air. Feeds also on fruit, but not often at trees (e.g. *Miconia*) with small berries; generally does not visit fruiting trees so often as do many other tanagers.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon in Ecuador and Peru. Status in Colombia uncertain, and few records; recorded above Churuyaco, on Nariño–Putumayo border, and probably also in W Caquetá. Range encompasses a number of protected areas, including, among others, Sangay, Llanganates and Podocarpus National Parks (Ecuador), El Condor Bi-national Park (Ecuador and Peru), and Cordillera de Colán, Tingo Maria and Cordillera Azul National Parks (Peru). No parks or reserves within its known distribution in Colombia, and deforestation there is ongoing and extensive. Range in Ecuador and Peru also includes much intact habitat that is not formally protected, but status of portions of this is unknown, and continuing deforestation is severe, at least locally. Overall, this species is not likely to become threatened in the near future so long as parks and reserves within its range are maintained, although populations in Colombia and locally elsewhere are almost certainly at risk.
Bibliography. Burns (1997a), Burns & Naoki (2004), Burns *et al.* (2002, 2003), Clements & Shany (2001), Hilty & Brown (1986), Lysinger *et al.* (2005), Mee *et al.* (2002), Meyer de Schauensee (1966, 1970a), Parker & Parker (1982), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010).



Genus *CYANICTERUS* Bonaparte, 1850

75. Blue-backed Tanager

Cyanicterus cyanicterus

French: Tangara cyanictère **German**: Ziertangare **Spanish**: Tangara Dorsiazul

Taxonomy. *Pyranga cyanicterus* Vieillot, 1819, probably Cayenne, French Guiana.
Monotypic.
Distribution. E Venezuela (R Yuruán; sight records also at San Isidro and foothills of Sierra de Lema) E across C Guyana and Suriname to French Guiana; also several tiny and presumably isolated populations in C Amazonian Brazil (one N of Manaus, the other S of R Amazon).
Descriptive notes. 17 cm; 33–36 g. Distinctive blue and yellow tanager with long, heavy bill with decurved culmen. Male has head, neck, upper breast, and upperparts, including upperwing-coverts

and tail, bright cadet-blue, more violet-blue on throat and chest; lores black; flight-feathers dusky, edged bright cobalt-blue; mid-breast to undertail-coverts golden-yellow, thigh dark blue; iris orange to red; upper mandible black, lower mandible grey; legs yellowish-orange. Female is similar to male, but duller, paler, more cerulean-blue, above with greenish tinge on back, rump and wing-coverts; lores, supercilium, side of head, throat and chest deep buffy yellow, becoming bright yellow on lower underparts. Juvenile apparently undescribed. Voice. Can be quite noisy. In SE Venezuela, both sexes, while perched or in flight, give high-pitched, loud and extremely penetrating calls (possibly song), mostly of 2 or 3 notes, e.g. "peeee, puuu" or "keeee, ksuuu-ksuuu", or various combinations, occasionally up to 5 notes in a series. In Alta Floresta, in Brazil, song, from high, often exposed perch, a slow series of single notes, pairs and triplets delivered in apparent random order, e.g. "pséép-pseep... peeps eep-eep, pee-eep, pséép-ee..." and so on for up to several minutes.

Habitat. Humid lowland forest, tall forest borders, and adjacent tall trees in small clearings close to forest; lowlands to c. 600 m.

Food and Feeding. Stomach contents in Suriname included beetles (Coleoptera) and bugs (Hemiptera, including homopterans). Reported as eating fruit of *Cupania* in French Guiana. Occurs in pairs and in little groups (possibly family parties) of up to about four individuals, high in forest canopy, in emergent trees, and may perch for short periods of time on bare branches protecting above canopy. Often with mixed-species flocks, but has habit of flying straight off to some distant high treetop, all the while calling loudly, and leaving flock behind, only to return again within 10–15 minutes. Forages by hopping in rather deliberate manner along open branches in canopy, where it peers downwards. Foraging territory apparently quite large, as pairs wander widely and their movements appear erratic and difficult to predict.

Breeding. No information.

Movements. Almost certainly resident; pairs or groups found year after year at certain localities in E Venezuela and in C Suriname.

Status and Conservation. Not globally threatened. Rare to uncommon, and possibly local; apparently absent from some seemingly suitable sites. Seems to occur normally at very low density. Confined largely to Guianan forests from extreme E Venezuela E to French Guiana, a region that has not yet suffered extensive deforestation. Because this species stays very high in forest, where difficult to detect except by voice, it could perhaps be somewhat more numerous than low frequency of sightings would suggest. Status of isolated C Brazil populations not known.

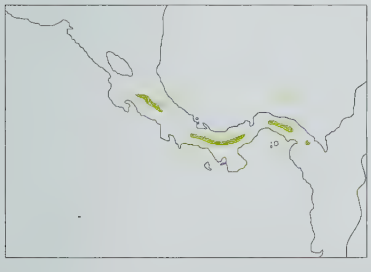
Bibliography. Davis (1980), Grantsau (1985), Haverschmidt (1968), Haverschmidt & Mees (1994), Hilty (2003), Ingels (1981), Marantz & Zimmer (2006), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Parkes (1969a), Phelps & Phelps (1950, 1963), Ridgely & Tudor (1989, 2009), da Silva & O'Neill (1986), Snyder (1966), Souza (2002), Tostain *et al.* (1992).

Genus *BANGSIA* T. E. Penard, 1919

76. Blue-and-gold Tanager

Bangsia arcaei

French: Tangara jaune et bleu **German**: Bangstangare **Spanish**: Tangara de Arcé



Taxonomy. *Buthraupis arcaei* P. L. Sclater and Salvin, 1869, Cordillera del Chucú, Veraguas, Panama.

In the past, genus sometimes subsumed in *Buthraupis*, but this treatment not supported by recent molecular-genetic studies, which place it in a separate clade, with *Wetmorethraupis* as sister to it; in addition, members of present genus are smaller in size and shorter-tailed than *Buthraupis*, relatively uniform in plumage, behaviourally less social and occur mostly at lower elevations. Recent specimens apparently of this species from Colombia may represent an undescribed form; study required. Two subspecies currently recognized.

Subspecies and Distribution.

B. a. caeruleigularis (Ridgway, 1893) – Caribbean slope of Costa Rica from extreme SE Guanacaste S to Cartago (including slopes of volcanoes Turrialba, Irazú, Barba and Poas).

B. a. arcaei (P. L. Sclater & Salvin, 1869) – W & E Panama (locally in C Bocas del Toro, Chiriquí and both slopes in Veraguas E to Coclé; vicinity of Cerro Jefe, also Cerro Brewster, in W San Blas). Also, race unknown, extreme NW Colombia (E side of Cerro Tacarcuna, in Acandí).

Descriptive notes. 15 cm; two birds 34·6 g and 39·9 g. Colourful tanager with bill strong and heavy for size of bird. Nominate race has crown and side of head cobalt-blue, lores black, upperparts dark navy-blue, tail dark dull navy-blue; lesser and median upperwing-coverts dusky blue, greater coverts dusky, rather broadly edged dark navy-blue; flight-feathers and tertials dusky, edged dull navy-blue; throat and upper chest dark navy-blue, breast, sides, flanks, thigh and lower underparts, including undertail-coverts, bright golden-yellow; iris dark red; bill black; legs blackish. Sexes similar. Immature is similar to adult, but duller; iris brown. Race *caeruleigularis* differs from nominate in having sides, flanks and thigh dark navy-blue (not bright golden-yellow). Voice. Song a halting series of high, thin notes and lispy, tinny whistles, "tip-sére, tip-séere, tip-tséere..."; described also as "ti-sicke, ti-sicke, ti-sicke" and so on. Calls include high, piercing "zeek" or "keep" and squeaky "spit" or "chit"; also a high, thin "tseeee-eeeet", sometimes shortened to "tseeee".

Habitat. Humid and wet foothill forest and pre-montane forest, and shrubs along forest borders; infrequently in trees in clearings adjacent to forest. At 300–1200 m.

Food and Feeding. Mostly arthropods and fruit. Takes variety of small fruits, and seen also to pluck flowers of epiphytes (e.g. *Satyria*) and squeeze out nectar; also observed to take cockroaches (*Blattaria*), an ant queen (Formicidae), and spiders (Araneae). Usually in pairs, although may be encountered singly, and occasionally in loose groups of three or four individuals when not breeding; regularly forages with mixed-species flocks that contain other tanagers, especially *Tangara* and *Chlorospingus*. Alternates periods of sluggishness or inactivity with abrupt buzzy, heavy flights, also rapid hopping along mossy branches and epiphytes, where it searches for food items. May pause to peer and peck at moss tufts or other epiphytes in deliberate manner for some moments before moving on. Sometimes reaches well below perch to take small fruit, a manoeuvre facilitated by its strong tarsi.

Breeding. Two nests recorded, one with young in Jul in Panama and one under construction in Apr in Costa Rica. Covered nest 10–12 m above ground, in hole in moss, one on side of branchless trunk, the other on large limb heavily covered with epiphytes and moss; in Costa Rica, presumed female brought matted rootlets to cavity while male sang. At Panama nest, an adult brought food, twice apparently mashed pulpy red fruit. No other information.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA and Darién Highlands EBA. Locally common to rare; declining. Has small range, with four geographically isolated populations, all of which believed to be declining as a result of deforestation, human settlement and degradation of forest habitat. Is, however, regarded as locally common along lower Caribbean slope of Cordillera Central and Cordillera de Tilarán, in Costa Rica, and also in adjacent W Panama. Few, if any, recent reports from Cerro Jefe area E of Canal Zone, but seen and photographed on Cerro Brewster, in W San Blas, in Apr 1985. A recently discovered population on Colombian side of Cerro Tacarcuna may be under greater threat than other populations because of ongoing deforestation in this region.

Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Davis (1972), Garrigues & Dean (2007), Isler & Isler (1999), Monroe *et al.* (1993), Remsen *et al.* (2010), Ridgely & Gwynne (1989), Robbins & Glenn (1988), Ross & Whitney (1995), Sedano & Burns (2010), Slud (1964), Stattersfield & Capper (2000), Stiles & Skutch (1989), Wetmore *et al.* (1984).

77. Black-and-gold Tanager

Bangsia melanochlamys

French: Tangara à cape noire **German**: Blauschultertangare **Spanish**: Tangara Negrigualda

Taxonomy. *Buthraupis melanochlamys* Hellmayr, 1910, La Selva, River Jamaraya, 4800 feet [c. 1460 m], Chocó, Colombia.

In the past, genus sometimes subsumed in *Buthraupis*, but this treatment not supported by recent molecular-genetic studies, which place it in a separate clade, with *Wetmorethraupis* as sister to it; in addition, members of present genus are smaller in size and shorter-tailed than *Buthraupis*, relatively uniform in plumage, behaviourally less social and occur mostly at lower elevations. Monotypic.

Distribution. Colombia: NW end of C Andes in Antioquia, and W slope of W Andes on Cerro Tatamá and Mistrató (including Alto de Pisones), on Chocó–Risaralda–Valle del Cauca border.

Descriptive notes. 15 cm; five males 35–44·5 g, three females 35–36·3 g. Robust, short-tailed tanager with thick, heavy bill and bicoloured appearance. Has entire head, mantle, back and rump dull black, uppertail-coverts contrastingly blue (usually hidden); tail dull black; bend of wing and lesser and median upperwing-coverts shining cerulean-blue (usually hidden), greater coverts black often with blue fringes; primary coverts black, flight-feathers and tertials dull black; throat, chest, sides, flanks and thighs dull black, patch on upper breast bright golden-yellow (in certain light appears as golden-orange stain), rest of breast (broad median area) down to belly and undertail-coverts bright yellow; iris dark red to dark maroon; bill black; legs blackish. Sexes similar. Immature undescribed. Voice. Song a very high-pitched, penetrating and thin "pit-séeya", repeated three or more times in quick succession. Contact call a sharp "tsit!"; when with mixed-species flocks, gives emphatic "pit-pit-pit!" and "spit-spit!"; single birds reported as occasionally giving a "pseee" or "pseeyee", longer than previous calls.

Habitat. Humid and wet pre-montane and montane forest (cloudforest) doubtless its primary habitat. Has been found also in trees adjacent to forest and in some regrowth and disturbed habitats, forest fragments and borders, where it probably ranges occasionally in search of food. Originally recorded at 1000–2285 m; recent records at 1400–1750 m.

Food and Feeding. Feeds heavily on fruit, including *Miconia* and *Cavendishia*; also arthropods. Stomach contents variously 75–100% fruit. Singles and pairs occur alone, also regularly with mixed-species flocks, and forage mostly at middle levels of forest. At least when with mixed flocks, regularly searches in moss and epiphytic growth on limbs for arthropod prey.

Breeding. Nest-building observed in Apr and juvenile seen in Jun. No other information.

Movements. Seasonal differences in relative abundance suggest possibility of post-breeding (e.g. after Jun or Jul) movement to higher elevations; further documentation needed.

Status and Conservation. VULNERABLE. Restricted-range species: present in Colombian Inter-Andean Slopes EBA and Chocó EBA. Fairly common to very locally common. Estimated population within small global range 1000–2499 individuals. Known from small area on N & W slopes of C Andes in Antioquia, where unrecorded from 1948 until rediscovered in 1999, on W side of R Nechí; found also on W slope of W Andes on Chocó–Risaralda–Valle border. Populations almost certainly declining. Both areas have undergone deforestation and human settlement, and continue to do so. In Antioquia, occurs at Reserva La Serrana (where may be locally fairly common) and in Reserva de Arrierito Antioqueño (Chestnut-capped Piha Reserve); a third, nearby population may be included within the proposed Caramanta National Park. In W Andes, the species is regarded as common in Tatamá National Park, but this area has been severely deforested and most forest below c. 1500 m has already disappeared; it occurs in intact forest above 1500 m on Cerro Mistrató (near Cerro Tatamá) and in another large block of intact forest around Alto de Pisones. Threats in these

On following pages: 78. Golden-chested Tanager (*Bangsia rothschildi*); 79. Moss-backed Tanager (*Bangsia edwardsi*); 80. Gold-ringed Tanager (*Bangsia aureocincta*).

areas include deforestation, mining, small-scale agriculture and new and proposed roads, which will only add to colonization pressure on remaining forest; despite the fact that region is inhabited by native Embera Indians, further colonization will lead to escalation of deforestation. Other complications include paramilitary activity, which has prevented survey work.

Bibliography. Álvarez-Rebolledo *et al.* (2007), Anon. (2010a), Butchart & Stattersfield (2004), Collar *et al.* (1992), Hilty (1985), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sedano & Burns (2010), Stattersfield & Capper (2000), Stiles (1998b).

78. Golden-chested Tanager

Bangsia rothschildi

French: Tangara de Rothschild **German**: Rothschildtangare **Spanish**: Tangara de Rothschild

Taxonomy. *Buthraupis rothschildi* Berlepsch, 1897, Cachabí, 500 feet [c. 150 m], Esmeraldas, Ecuador.

In the past, genus sometimes subsumed in *Buthraupis*, but this treatment not supported by recent molecular-genetic studies, which place it in a separate clade, with *Wetmorethraupis* as sister to it; in addition, members of present genus are smaller in size and shorter-tailed than *Buthraupis*, relatively uniform in plumage, behaviourally less social and occur mostly at lower elevations. Monotypic.

Distribution. W Colombia (from C Chocó) S on Pacific slope to Ecuador (N Esmeraldas and SW Imbabura).

Descriptive notes. 15 cm; one male 48·5 g. Chunky, short-tailed tanager with relatively heavy bill. Plumage is almost entirely dark navy-blue; rump and uppertail-coverts slightly bluer, tail dusky, edged dark blue; upperwing-coverts blackish, narrowly edged dark blue, primary coverts blackish, flight-feathers blackish, narrowly edged pale blue; tertials dusky, broadly edged dull dark blue (darker blue than flight-feather edging); below, mostly dark navy-blue to blackish with shiny lustre, large contrasting golden-yellow patch in form of broad crescent across upper breast, plain yellow centre of belly to undertail-coverts; iris dark reddish-brown; bill and legs black. Sexes similar. Immature undescribed. Voice. Song, infrequently heard, a high, buzzy, insect-like "tiz-ez-ez-ez-ez-ez", given up to ten times per minute; one was once observed to sing more or less uninterruptedly for several minutes from exposed perch above canopy. Infrequently heard call a shrill, high-pitched "kjeee".

Habitat. Wet and pluvial foothill forest and pre-montane forest and forest borders. Mostly 250–1100 m; recorded as low as c. 150 m in Ecuador.

Food and Feeding. Fruit, some nectar; also arthropods. Recorded as eating more than ten species of fruit, including those from melastomes, *Cecropia*, figs (*Ficus*) and several epiphytes, including mistletoe (Loranthaceae). Pairs and single birds regularly associated with mixed-species flocks that contain other tanagers and frugivores. Like congeners, alternates bouts of sluggishness with more active periods of heavy hopping and peering along branches and in foliage, where it regularly cocks tail and executes "about-face" movements on open branches; flight from tree to tree heavy and direct, with rather buzzy wingbeats, reminiscent of flight of a barbet (Capitonidae). In W Valle (Colombia), foraged mainly inside outer foliage in middle levels and crowns of medium-sized trees (10·5–17 m tall), occasionally moving lower. Takes most fruit while perched, but occasionally hovers in front of fruits that are difficult to reach. Berries may be swallowed whole or mashed, and seeds and fruit removed from arils and capsules. Observed to forage for insects on both bare and mossy branches and leaf petioles, and sallies short distances to air. Seen to remove petals from flowers and squeeze centres for nectar.

Breeding. One with nesting material on 24th Jun in upper Anchicayá Valley (W Valle), in Colombia. No other information.

Movements. Occasional local or seasonal upslope movements on Pacific slope in Colombia, with birds present as high as 1050 m only in Nov and Mar.

Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Uncommon to locally fairly common. Regarded as "Near-threatened" in Ecuador because of its limited distribution and small amount of remaining suitable habitat. Like many foothill species, is in decline as a result of deforestation, which continues to reduce available habitat throughout its range. Occurs in a few protected areas, among them Farallones de Cali National Park, in Valle del Cauca, and the privately operated El Pangan, in W Nariño, but coca-growing and other illegal activities nearby threaten the integrity of latter reserve.

Bibliography. Collar *et al.* (1992), Dunning (1982), Haffer (1967b), Hartert (1898), Hilty (1977), Hilty & Brown (1986), Isler & Isler (1999), Jahn *et al.* (2002), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sedano & Burns (2010).

79. Moss-backed Tanager

Bangsia edwardsi

French: Tangara d'Edwards **German**: Edwardstangare **Spanish**: Tangara de Edwards

Taxonomy. *Buthraupis edwardsi* Elliot, 1865, Colombia.

In the past, genus sometimes subsumed in *Buthraupis*, but this treatment not supported by recent molecular-genetic studies, which place it in a separate clade, with *Wetmorethraupis* as sister to it; in addition, members of present genus are smaller in size and shorter-tailed than *Buthraupis*, relatively uniform in plumage, behaviourally less social and occur mostly at lower elevations. Monotypic.

Distribution. W slope of W Andes in SW Colombia (from Dagua Valley, in Valle del Cauca) S to NW Ecuador (Esmeraldas and Pichincha).

Descriptive notes. 15 cm; 33·5–39·4 g. Chunky tanager with blue face and thick stubby bill. Has entire crown, lores, ocular area and throat black, supercilium (from above eye) and side of head pale shining blue; upperparts, including uppertail-coverts, uniformly dark moss-green, tail feathers dusky, outer webs dull dark green; lesser and median upperwing-coverts dark green, tinged dark blue, greater coverts dusky, tinged dark blue and very narrowly edged pale blue (inconspicuous); flight-feathers dusky, secondaries inconspicuously edged bluish, tertials dusky, outer half of each feather obscurely tinged dark green; golden-yellow patch on chest flanked by dark olive or even blackish smudging on sides of chest; rest of underparts, including undertail-coverts, dark dull green, rather ill-defined yellow band extending down centre of underparts from chest to belly; iris

dark brown; bill dusky above, pale pinkish-yellow below; legs blackish. Sexes similar. Immature is much like adult, but considerably duller, especially on upperparts, has throat and chest dusky olive, weakly defined yellowish patch on central chest, rest of underparts dull yellowish-olive. Voice. Dawn song, from prominent perch, a chippy, rattling trill, "tr'e'e'é' é'e'e'r tr'e'e'é'é'e'e'r...", rising and falling in pitch, continuing for up to a minute more or less without interruption.

Habitat. Wet and pluvial pre-montane and montane forest (cloudforest) and forest borders; infrequently ventures out into scattered trees in small gaps and clearings adjacent to wet forest. Recorded at 400–2100 m; in Colombia, most records above 900 m in Nariño and above 1200 m in W Valle del Cauca; c. 500–1700 m in Ecuador.

Food and Feeding. Fruit and arthropods. In W Colombia ate mostly fruit, including several species of melastome, epiphytes, and parasitic plants. Encountered most often in pairs; a regular associate of mixed-species flocks containing other tanagers, but also forages away from flocks. Rather lethargic, often alternating active foraging bouts with periods of perching quietly, sometimes on a rather open stub or branch overlooking forest; flies in direct and heavy manner, with rather buzzy flight, from tree to tree. Forages mainly in middle and upper strata of forest. Seen to pick berries from a perched position and to peck soft parts from larger fruits; hopped slowly along branches, where peered at moss and foliage, also took insects off foliage and flutter-pursued escaping prey or sallied short distances to air. Has been observed also to take fruit from Araceae spikes by clinging to sides of the fruit. In W Andes of Colombia, once seen to forage for 12 minutes at a swarm of *Labidus praedator* army ants, where it took fruit and captured insects 0·4–2 m above the ants, mostly by sallying and lunging for prey disturbed by the ants.

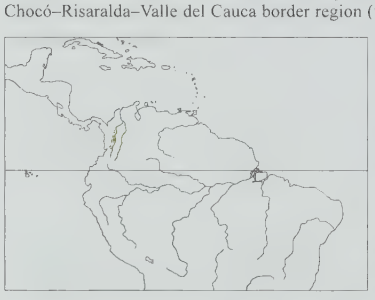
Breeding. Nest with eggs found at end Jul in Ecuador; stub-tailed young with adult in Jan in Colombia (upper Anchicayá Valley, in W Valle). Ecuador nest a cup 65 mm in width, 30 mm deep, composed of three species of fern (including *Dryopteris*) and moss, with lining of fine wavy vines, placed 2 m above ground at fork of two small branches and near base of understorey tree (forest height c. 20 m), at 670 m on wet-forest ridge; contained 2 eggs, white, finely speckled reddish-brown at small end, more heavily at large end, dimensions 26·5 × 18·2 mm and 25·5 × 18·8 mm. No other information.

Movements. Possibly some local movement; wandering individuals reported in Mar and Nov at 1050 m elevation in upper Anchicayá Valley, at a site where species not resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Locally fairly common in both Colombia and Ecuador. Although this species is generally found at higher elevation and is more numerous than *B. rothschildi*, it has a similarly small global distribution and faces similar threats, including extensive and ongoing deforestation almost throughout its range. In Colombia, occurs within lower portions of Farallones de Cali National Park, in Valle, El Pangan Reserve, in Nariño, and probably Munchique National Park, in Cauca. May utilize older second growth and forest edge, and probably tolerates, to some extent, some disturbance within its habitat.

Bibliography. Dunning (1982), Haffer (1967b), Hilty (1974, 2009b), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1964, 1966, 1970a), Moore *et al.* (1999), Orejuela & Cantillo (1990), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Robbins & Glenn (1988), Salaman *et al.* (2008), Sedano & Burns (2010).

80. Gold-ringed Tanager



Bangsia aureocincta

French: Tangara à boucles d'or **German**: Goldringtangare **Spanish**: Tangara del Tatamá

Taxonomy. *Buthraupis aureocincta* Hellmayr, 1910, Cerro Tatamá, 6700 feet [c. 2040 m], Chocó, Colombia.

In the past, genus sometimes subsumed in *Buthraupis*, but this treatment not supported by recent molecular-genetic studies, which place it in a separate clade, with *Wetmorethraupis* as sister to it; in addition, members of present genus are smaller in size and shorter-tailed than *Buthraupis*, relatively uniform in plumage, behaviourally less social and occur mostly at lower elevations. Monotypic.

Distribution. W Andes of Colombia: Las Orquideas National Park (W Antioquia), and four sites in Chocó–Risaralda–Valle del Cauca border region (vicinity of Cerro Tatamá).

Descriptive notes. 16 cm; male 39·5–46·6 g, female 44·6–46·5 g. Small and rather dark, with distinctive facial pattern. Male has lores, entire crown and side of head deep black, with conspicuous horseshoe-shaped golden-yellow ring formed by post-ocular supercilium extending rearwards, then down around ear-coverts, and then forwards as broad golden-yellow malar; upperparts, including uppertail-coverts, dark moss-green, tail dusky, tinged dark moss-green; upperwing-coverts dull dark blue, primary coverts blackish, narrowly and obscurely edged dark blue; primaries plain dusky (no edging), secondaries dusky, narrowly edged dull dark blue, tertials dusky, outer half of each feather obscurely tinged dull dark blue (inconspicuous); throat black, black spreading out onto side of chest, large, conspicuous bright golden-yellow patch on chest; entire rest of underparts dark dull green; iris deep reddish-brown; bill dusky above, dull yellowish-orange below; legs blackish. Female has same golden-yellow head markings as male, but head dark moss-green (not black) like rest of upperparts; throat and side of chest dark dusky moss-green (not black). Immature undescribed. Voice. Song a sharp, high-pitched "tseeeeuuur" in groups of c. 3–6 notes. Call a sharp "chit" and "chip"; short low trill in alarm.

Habitat. Occupies wet mossy montane forest (cloudforest), especially along ridges, at elevations of c. 1600–2200 m. Habitat similar to that of *B. melanochlamys*, but present species generally at higher elevations.

Food and Feeding. Few data. Diet fruit and arthropods; stomachs examained contained 70–90% fruit; takes insects when foraging in mixed-species flocks. Found in pairs, sometimes joining mixed-species flocks. Forages more in lower part of forest than does *B. melanochlamys*; behaviour otherwise similar to that of latter.

Breeding. Season Feb–Jul; nests found in Mar and Jul, female feeding fledglings in Jun and stub-tailed juveniles seen in Jul, also male carrying nest material in Dec. Two nests recently found, one completely hidden underneath a bromeliad on horizontal branch 6 m above ground; the other a large domed ball 23·6 cm wide, 16·2 cm deep, and 14·5 cm tall (domed roof comprising 5·8 cm of total height), entrance 8·2 cm wide and 6·8 cm tall, constructed from moss, lined with rootlets, supported by triple fork 2·3 m above ground in thin shrub 2·7 m tall, and supported also by stems of two similar nearby shrubs bent down into the fork. Second nest attended by three adults (two males and one female), indicating possible co-operative breeding. No other information.
Movements. No information. Presumably resident.
Status and Conservation. ENDANGERED. Restricted-range species: present in Chocó EBA. Rare to uncommon; locally common. Estimated global population fewer than 2500 individuals within total range of c. 670 km². Four specimens taken near Cerro Tatamá, on Chocó–Risaralda–Valle del Cauca border, between 1909 and 1946; not found in surveys in 1990s, and possibly now extinct there. Currently known from five sites in W Andes: Alto de los Galápagos (at 1750–2100 m), W of Tuluá, on Valle del Cauca–Chocó border; Cerro Tatamá, on Chocó–Valle del Cauca border; Mistrató, in Risaralda; Alto de Pisones (at 1600–1800 m), on Cerro Caramanta, on Antioquia–Risaralda border, where common to very common; and Las Orquídeas National Park, NW of Medellín, in Antioquia. Deforestation has been widespread throughout this species' presumed former range, and has been particularly severe on Cerro Tatamá, where type locality lies within Tatamá National Park; recently discovered nearby populations are unprotected. Cerro Caramanta may hold the largest block of intact forest (from c. 800 m up to 2000 m) where this species could occur. Mining, logging, small-scale agriculture and human settlement threaten all of these areas, including Tatamá National Park. Effective protection of forest an urgent conservation priority for this and other species in the region.

Genus *WETMORETHRAUPIS*

Lowery & O'Neill, 1964

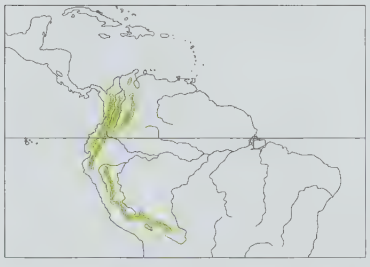
81. Orange-throated Tanager

Wetmorethraupis sterrhopteron

French: Tangara à gorge orangée **Spanish**: Tangara Golinaranja
German: Veilchenschultertangare
Other common names: Wetmore's Tanager

Taxonomy. *Wetmorethraupis sterrhopteron* Lowery and O'Neill, 1964, Chávez Valdivia, Amazonas, Peru.
Molecular studies place present species as sister to *Bangsia*; differs from other genera in family in stiff, bristly throat feathers, although this condition is approached in *Spindalis*. Monotypic.
Distribution. Extreme S Ecuador (SE Zamora-Chinchipe) and adjacent N Peru (NC Amazonas).

Descriptive notes. 17 cm; 43·6–56 g. Strikingly plumaged, thick-billed tanager with relatively long wing, but short tail and tarsus; feathers of malar region, lower chin and throat stiff, almost bristly, and with waxy appearance. Has top and side of head, lores, chin, side of neck and upperparts, including uppertail-coverts, velvety black, tail matt black; bend of wing greyish-blue, marginal coverts, lesser upperwing-coverts and lower half of median coverts deep blue, upper half of medians black, edged and tipped same blue colour, greater coverts blackish, broadly edged and tipped light violet-blue; alula and primary coverts black, narrowly edged blue; primaries black, secondaries and tertials black, edged pale violet-blue; throat and upper chest deep cadmium-orange, feathers of chest with burnished quality, rest of underparts buff-yellow, thigh black; underwing-coverts blackish-slate, a few feathers edged blue; iris dark brown; bill and legs black. Sexes similar. Juvenile apparently undescribed. VOICE. Dawn song, in Peru, a thick, heavy "jasuu, jasuu, jasuu...", up to a half-dozen notes, repeated over and over with scarcely a pause; also (possibly also day song), from high perch, a much higher-pitched, squeaky, slurred series of 3-note phrases, e.g. "we-tsí-tsoo, we-tsí-tsoo", described also as "in-chúé-tooch", first note high (often inaudible at distance), second syllable loudest. Call a soft, penetrating "seet".
Habitat. Mainly mature humid and wet pre-montane forest in relatively gentle foothills, and *terra firme* forest in adjacent lowlands; reported also in disturbed mature forest. Recorded at c. 450–800 m in Peru; 600–1000 m in Ecuador.
Food and Feeding. Fruit and insects. One stomach contained seeds, fruit pulp and a beetle (Coleoptera). Found in pairs and in small groups of up to about six individuals, foraging in middle storey to canopy; sometimes with mixed-species flocks, but more often away from them. Fairly conspicuous. Scans leaves, and searches mosses and small bromeliads as it hops along branches; has been seen while foraging in *Cecropia* trees, and hovering, presumably to take fruit, at tips of branches. Apparently ranges over large areas.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Andean Ridge-top Forests EBA. Notably local; fairly common in suitable habitat at a few sites. First described in 1964 in Peru, and more recently (1990) found in Ecuador. This species was first brought to the attention of scientists by indigenous hunters living in vicinity of type locality. In extreme S Ecuador, recorded above R Nangaritza on W slope of S Cordillera del Cóndor, in SE Zamora-Chinchipe. In adjacent Peru, recorded in NC Amazonas S to Urakusa on lower E slopes and foothills above R Cenepa, and from regions S of R Marañón opposite mouth of R Cenepa; reported by native Aguaruna tribe as occurring also at headwaters of R Nieva (also in Amazonas), a locality some distance SE of the species' known range. In S Ecuador, seen regularly on Shaur indigenous land (near village of Shaime, on R Nangaritza) in Cordillera del Cóndor. Widespread forest destruction has taken place within its very small known global range in S Ecuador and N Peru, and none of the land within its range is protected as yet. The loss of some forest has occurred within the last 20 years (since 1990) within its tiny range in Ecuador, where recent authors regard the species as "Endangered"; it appears that it is in decline in all areas. Further field surveys required in order to determine the species' precise distribution.
Bibliography. Anon. (2010a), Begazo *et al.* (2001), Butchart & Stattersfield (2004), Capper & Pereira (2007), Clements & Shany (2001), Isler & Isler (1999), Lowery & O'Neill (1964), Lysinger *et al.* (2005), Marin *et al.* (1992), O'Neill (1969), van Oosten *et al.* (2007), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Sedano & Burns (2010), Stattersfield & Capper (2000).



Genus *BUTHRAUPIS* Cabanis, 1851

82. Hooded Mountain-tanager

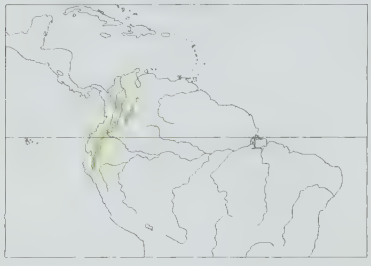
Buthraupis montana

French: Tangara montagnard **German**: Blaurücken-Bergtangare **Spanish**: Tangara Montana

Taxonomy. *A.[glaia] montana* d'Orbigny and Lafresnaye, 1837, Yungas, Bolivia.
Birds from Venezuela proposed as a separate race, *venezuelana*, but validity of this requires confirmation. Five subspecies currently recognized.
Subspecies and Distribution.
B. m. gigas (Bonaparte, 1851) – Venezuela (Sierra de Perijá, and Andes of S Táchira) and adjacent E Andes of Colombia (S to Cundinamarca).
B. m. cucullata (Jardine & Selby, 1842) – W & C Andes of Colombia S to Ecuador.
B. m. cyanonota Berlepsch & Stolzmann, 1896 – Andes of N & C Peru (Amazonas S to Junín).
B. m. saturata Berlepsch & Stolzmann, 1906 – Andes of SE Peru (Cuzco and Puno).
B. m. montana (d'Orbigny & Lafresnaye, 1837) – Andes of N Bolivia (La Paz, Cochabamba and W Santa Cruz).

Descriptive notes. 21 cm, 69–91 g (nominate); 23 cm, 72–116 g (other races). Largest mountain-tanager; distinctive rotund shape and conspicuous red eyes, short and thick bill. Nominate race has head and throat black, small amount of black extending down onto side of chest and breast (often concealed), hindcrown and nape (nuchal collar) shining pale milky blue, contrasting sharply with dark shining blue back and rest of upperparts; lesser upperwing-coverts blue, median and greater coverts black, edged blue, primary coverts black, flight-feathers blackish, inner primaries and all of secondaries edged blue, tertials black, broadly edged blue; tail feathers black, edged blue; breast and lower underparts golden-yellow, narrow blue-and-black band from flank extending onto thigh (like dark garter); iris bright red; bill blackish above and below, basal half of lower mandible often paler bluish-grey; legs blackish. Sexes similar. Immature is paler and duller, especially below, than adult. Races differ in size, nominate smallest, others lack obvious pale nuchal collar, have base of lower mandible pale blue-grey (not pinkish), and differ slightly in tone of upperparts: *cyanonota* is closest to nominate, but larger; *cucullata* is shining windsor-blue above, paler than nominate; *saturata* is shining violaceous blue above; *gigas* is dull purplish-blue above. VOICE. During flight display, presumed male sings rapid, exuberant "chip'ut-chip'ut-chip-ut..." as he flies out high in large 100-m circle above forest, before diving back into forest. Apparent dawn song a single "weeck!" or "too-weeck" repeated monotonously over and over at rate of about once per second. Also gives repeated "tsee-tsee-tseét?". Group-members, sometimes stimulated by extraneous noises, simultaneously give loud bursts of squealing notes; also, during foraging, "weeck" and "too" notes, or "too-weeck" phrases, often rapidly; also weak "ti" notes singly or in rapid series.
Habitat. Mainly humid and wet montane forest and forest borders; also tall second-growth woodland, scattered trees in clearings adjacent to forest, and stunted or elfin forest and scrub woodland near tree-line. Mostly at 1900–3500 m; 1800–3000 m in Venezuela, and once (possibly a vagrant) as low as 1100 m on Pacific slope of Colombia.
Food and Feeding. Arthropods, also many small berries and fruit. Of 35 stomachs examined, 34 contained only vegetable matter and one contained both animal and vegetable matter; items included fruit pulp, berries, seeds, including grass seeds (Poaceae), leaves and beetles (Coleoptera). Social, often seen in conspicuous groups of 3–10 individuals, occasionally more, that roam over large areas, and sometimes rather confiding. Flocks move along steep forested slopes or canyons, often crossing considerable gaps with each flight, stragglers hurrying along to keep up with faster-moving members. Regularly occurs in loosely associated mixed flocks with Southern Mountain (*Cacicus chrysonotus*) and Northern Mountain Caciques (*Cacicus leucoramphus*) and jays (Corvidae), when forages rapidly, but only infrequently with mixed flocks of smaller species. Away from mixed-flock associations, forages in slower methodical manner on bare or mossy branches c. 25 mm or more in diameter. Forages mainly in middle and upper strata of trees, occasionally lower. Hops up through outer-canopy limbs, leans down to inspect sides of branches, especially to examine lichens on branch surfaces; also noted as taking prey from foliage, and may examine flowers, seedpods and even dead-leaf clusters.
Breeding. No information.
Movements. Resident. A few scattered records, probably of wandering or vagrant birds, at elevations lower than usual.
Status and Conservation. Not globally threatened. Fairly common throughout its wide latitudinal distribution in Andes. Generally occurs at rather low density, perhaps because groups wander over large areas of forest. Deforestation has fragmented this species' range in many areas, but it occurs in many protected areas, from Venezuelan Andes S to Bolivia; among them are Guaramacal and Sierra Nevada National Parks (Venezuela), Chingaza and Puracé National Parks and Tambito Nature Reserve (Colombia), Sangay and Las Cajas National Parks (Ecuador), Tingo Maria and Manu National Parks (Peru) and Isiboro-Sécure and Amboró National Parks (Bolivia). This species is found also in many areas of unprotected montane forest in Andes.
Bibliography. Álvarez-Rebolledo & Córdoba-Córdoba (2002), Aveledo Hostos & Pérez Chinchilla (1989), Burns (1997a), Burns & Naoki (2004), Burns *et al.* (2002, 2003), Donegan & Dávalos (1999), Dunning (1982), Fjeldsa & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Jacobs & Walker (1999), Krabbe *et al.* (2001), Remsen & Parker (1984), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010), Walker (2001), Weske (1972), Yuri & Mindell (2002), Zimmer (1944).

83. Black-chested Mountain-tanager



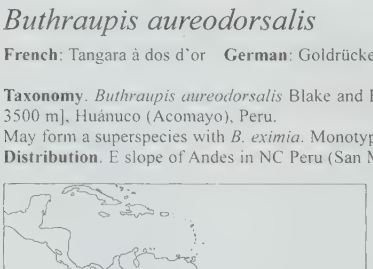
Buthraupis eximia

French: Tangara à poitrine noire **Spanish**: Tangara Dorsiverde
German: Schwarzbrust-Bergtangare
Other common names: Blue-rumped Mountain-tanager

Taxonomy. *Tanagra eximia* Boissonneau, 1840, Santa Fé de Bogotá, Colombia.
May form a superspecies with *B. aureodorsalis*. Four subspecies recognized.
Subspecies and Distribution.
B. e. eximia (Boissonneau, 1840) – Andes of SW Venezuela (S Táchira) and adjacent Colombia (Norte de Santander and Cundinamarca).

On following pages: 84. Golden-backed Mountain-tanager (*Buthraupis aureodorsalis*); 85. Masked Mountain-tanager (*Buthraupis wetmorei*); 86. Santa Marta Mountain-tanager (*Anisognathus melanogenys*); 87. Lacrimose Mountain-tanager (*Anisognathus lacrymosus*); 88. Scarlet-bellied Mountain-tanager (*Anisognathus igniventris*); 89. Blue-winged Mountain-tanager (*Anisognathus somptuosus*); 90. Bolivian Mountain-tanager (*Anisognathus flavinucha*); 91. Black-chinned Mountain-tanager (*Anisognathus notabilis*).

B. e. zimmeri R. T. Moore, 1934 – Colombia at N end of W Andes (*páramos* of Frontino and Paramillo) and in C Andes (Caldas–Antioquia border S to Tolima).
B. e. chloronota P. L. Sclater, 1855 – S Colombia on both slopes of Andes (from Huila and Cauca) S to NW Ecuador.
B. e. cyanocalyptra R. T. Moore, 1934 – Andes of S Ecuador S to N Peru (S to E Piura and N Cajamarca, mostly N of R Marañón).



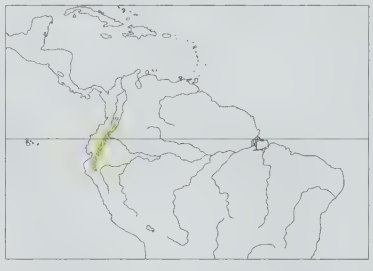
Descriptive notes. 18–22 cm; 50–70 g. Dark-plumaged, quiet tanager with short, thick bill, usually a few stiff bristles on chin. Nominate race has crown and nape silky cornflower-blue, mantle and back moss-green, rump and long uppertail-coverts silky blue (like crown); lesser and median upperwing-coverts blue (often partly concealed), greater coverts leaf-green with dark bases, flight-feathers black, secondaries edged green, tertials mostly dull green with dusky inner webs; tail black; lores, ocular area, and side of head to throat and chest black, rest of underparts golden-yellow, sometimes with sides narrowly dark mossy green (usually hidden); undertail-coverts duller; iris dark reddish-brown; bill black; legs dark grey. Sexes similar. Juvenile apparently undescribed. Race *zimmeri* differs from nominate in having rump mixed blue and dark green; *cyanocalyptra* differs in having rump and uppertail-coverts all dark moss-green, like back, and central throat with small concealed white patch; *chloronota* is larger than others, has duller blue head, black of mask less sharply separated from adjoining blue, rump and tail-coverts all dark green (like previous), lacks bristles on chin. Voice. Dawn song a simple series of alternating notes, the first lower, e.g. "tchew syéeuw, tchew syéeuw, tchew syéeuw"; also a more complex song lasting up to 30 seconds, e.g. "tititi-turri-tititi-tee-ter-turry..."; neither song heard frequently. Variety of soft "seep" notes, "chip" notes and forced "piz-weet" and soft "weeur", etc. during foraging.
Habitat. Wet mossy montane forest, along forest borders and in elfin woodland near tree-line. Recorded at 2000–3800 m, mostly c. 2750–3400 in Colombia and Ecuador, and mainly 2850–3300 m in N Peru. Largely replaces *B. montana* at higher elevations.
Food and Feeding. Mostly fruit; also insects. In Colombia recorded as taking fruit from Ericaceae, *Miconia* (Melastomataceae), and *Hedyosmum* (Chloranthaceae). Seven stomachs all contained vegetable matter, including seeds and fruit pulp. Found singly, in pairs and sometimes in small groups of 3–6 individuals, most often alone, but sometimes with mixed-species flocks. Quiet; moves rather heavily and methodically along mossy branches, mostly within dense foliage of trees and shrubs, and sometimes sits quietly, without moving, for several minutes in crown of small to large tree. In general much less conspicuous than *B. montana*. Searches for insects in moss and other canopy epiphytes.
Breeding. No information.
Movements. Presumed resident; little information.
Status and Conservation. Not globally threatened. Generally uncommon to rare. Uncommon in Venezuela. Rare to uncommon and somewhat local in Ecuador and Colombia, where most numerous at higher elevations; often found in elfin woodland at tree-line. In Peru, race *cyanocalyptra* confined to a narrow corridor of upper montane forest in extreme N, generally N of R Marañón, but two records S of Marañón Valley. Occurs at rather low density, and deforestation has fragmented this species' range in many areas; in Peru, deforestation and human settlement have been expanding since c. 1980. Present in numerous protected areas, among them Chingaza and Puracé National Parks (Colombia) and Cayambe, Sangay, Las Cajas and Podocarpus National Parks (Ecuador).
Bibliography. Álvarez-Rebolledo *et al.* (2007), Anon. (2000), Barnes *et al.* (1997), Botero *et al.* (2005), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Krabbe, Flórez *et al.* (2006), Krabbe, Moore *et al.* (2001), Meyer de Schauensee (1964, 1966, 1970a), Moore (1934a), Olivares (1969), Parker *et al.* (1985), Remsen *et al.* (2010), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sibley & Monroe (1990).

84. Golden-backed Mountain-tanager

Buthraupis aureodorsalis

French: Tangara à dos d'or **German**: Goldrücken-Bergtangare **Spanish**: Tangara Dorsidorada

Taxonomy. *Buthraupis aureodorsalis* Blake and Hocking, 1974, Quilluacocha, c. 11,500 feet [c. 3500 m], Huánuco (Acomayo), Peru.
May form a superspecies with *B. eximia*. Monotypic.
Distribution. E slope of Andes in NC Peru (San Martín, La Libertad and Huánuco).



Descriptive notes. 23 cm; 75–94 g. Large, spectacular but hard-to-find tanager; bill short and thick. Has crown dull blue, rest of head down to upper mantle and mid-breast black; rest of mantle, scapulars, rump and uppertail-coverts bright orange-yellow with sparse and rather obscure dusky and brownish markings; lesser upperwing-coverts blue, like crown (but often hidden), median and greater coverts, flight-feathers, tertials and tail deep black; lower breast, belly, sides and flanks bright orange-yellow (like back), belly and sides also with sprinkling of arrow-like bright chestnut spots and streaks (markings decreasing in size rearwards), undertail-coverts and lower belly chestnut, thigh commonly yellow at front but chestnut behind or on inside; axillaries bright yellow, undersurface of wing black, except for small patch of yellow on outer edge of bend of wing; iris dark brown; bill blackish above, paler below; legs dark grey. Sexes similar. Immature is similar to adult, but duller and with little blue on lesser wing-coverts. Voice. Song a series of wheedles, squeals and churrs; typically, repeats one note 4–6 times and then switches to another in rather staccato series given hurriedly and rhythmically. Variety of sharp, metallic and sometimes squeaky notes, including "chit", "wheet" and "heet", singly or repeated, and thin chittering "sweet" or "sweee" notes, all of them surprisingly weak for so relatively large a bird, and frequently given by foraging groups, sometimes for lengthy periods of time; sharp "steet-steet" in flight.
Habitat. Elfin forest at tree-line; especially in large islands and patches of *Escallonia* and *Clusia* woodland surrounded by grass at tree-line, and frequently along ridges enveloped in clouds. Occasionally in scattered low trees and scrub in more open areas near elfin forest. At 3150–3500 m.
Food and Feeding. Fruits and insects. Of seven stomachs examined, five contained only vegetable matter and two contained both vegetable and animal matter; contents included fruit pulp, seeds, and a beetle (Coleoptera) 8 mm long. Usually seen in inconspicuous pairs, less often in small parties of 3–5 (occasionally up to 7) individuals, which forage alone or sometimes join small mixed-species flocks. Regularly flies off some distance in undulating flight to new patch of woodland; typically, first bird calls as it takes flight, is quickly followed by others in rapid succession, and, once they arrive, they rest or forage. Forages from ground to treetops, mostly at middle heights in small trees and shrubs, often c. 3 m up. Moves quietly and slowly, hanging or leaning downwards to peck items from moss and lichens on branches, or occasionally from leaves. Most prey items believed to be taken from moss.
Breeding. Brooding females in Sept, and juveniles and immatures found in Jul, Oct and Nov. No other information.
Movements. Presumed resident; no evidence of any movements.
Status and Conservation. ENDANGERED. Restricted-range species: present in North-east Peruvian Cordilleras EBA. Uncommon to locally fairly common. Estimated global population very small, and declining as a result of loss of habitat, especially of tree-line *Polylepis* and other trees and shrubs of elfin woodland. Currently known from five sites within restricted area of Cordillera Central in Peruvian departments of San Martín, La Libertad and Huánuco; may occur in other, unexplored regions nearby, but to date has not been found farther N (in Cordillera de Colán). Occurs at low density in Río Abiseo National Park (San Martín), where noted only three times in 27 days of field survey; possibly easiest to find in Carpish Ridge region at Quilluacocha and Bosque Unchog, in Huánuco. Continued destruction of tree-line woodlands represents a major threat to this species; spread of fires from adjacent grassland also a cause of serious concern.
Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Clements & Shany (2001), Fjeldså & Krabbe (1990), Isler & Isler (1999), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sibley & Monroe (1990), Stattersfield & Capper (2000).

85. Masked Mountain-tanager

Buthraupis wetmorei

French: Tangara de Wetmore **German**: Wetmorebergtangare **Spanish**: Tangara de Wetmore

Taxonomy. *Tephrophilus wetmorei* R. T. Moore, 1934, south-east end of Culebrillas Valley, Ecuador.
Originally described in a monotypic genus, *Tephrophilus*; molecular-genetic studies indicate that this species is only distantly related to other members of present genus, and that it should probably either be returned to original genus or placed in enlarged genus containing numerous other mountain-tanagers. Monotypic.
Distribution. C Andes of SW Colombia (Quindío, and S on both slopes in Cauca and Huila to Nariño), S through Ecuador (mostly on E slope, from Carchi, W Napo and W Morona-Santiago S to E Loja and S Zamora-Chinchipe) and adjacent NW Peru (along Piura–Cajamarca border).

Descriptive notes. 20 cm; two birds 62 g and 63 g. Large, stubby-billed tanager with rather odd plumage pattern. Male has crown and nape yellowish-olive, becoming plain olive-green on back and contrasting yellow on rump; side of head down to foreneck black, forming rather broad, "drooping", roundish mask, forehead and narrow band more or less surrounding mask yellow (much brighter than crown); lesser and median upperwing-coverts dark violet-blue (often hidden), greater coverts black, edged and more broadly tipped dark violet-blue; flight-feathers black, outer feathers narrowly edged dark green, secondaries and tertials more broadly edged and tinged dark green; tail blackish; underparts bright mustard-yellow, usually forming a peak over central foreneck or even to lower throat, sides, flanks and sometimes belly mixed and stained with dusky and olive; iris dark brown; bill blackish, loewr mandible often grey except for blackish tip; legs dark grey. Female is similar to male, but slightly duller. Juvenile apparently undescribed. Voice. Notably quiet. Infrequently heard song a rather long series of high-pitched "tsee" notes, variable in intensity, and remarkably weak for such a large bird; reminiscent of a hummingbird (Trochilidae). Rather low, husky "juur-juur-juur-jur", possibly as alarm or contact, on taking flight.
Habitat. Low mossy forest and very humid elfin woodland, bamboo, and giant grasses at or near tree-line, and in islands of mossy scrub woodland surrounded by grass; at 2900–3650 m.
Food and Feeding. Fruit and apparently some insects. Contents of one stomach a large number of seeds. Found singly, in pairs and in little groups up to four individuals, usually seen when accompanying mixed-species flocks containing other tanagers, *Buarremon* brush-finches etc. Tends to forage mostly within cover, and apt to be seen first as it perches up to fly across small opening. Hops sluggishly as it searches for fruit and other items; once seen to sally clumsily after a flying insect.
Breeding. No information.
Movements. No information.
Status and Conservation. VULNERABLE. Restricted-range species: present in Central Andean Páramo EBA. Generally rare to uncommon; localized. Estimated global population not exceeding 5000 individuals, and probably declining. In Colombia, found at S end of C Andes on both slopes in Cauca and Huila, and recently reported farther N in department of Quindío, also recent sight records in Nariño at Volcán Galeras (SW of Pasto, at 3450 m); present in Puracé National Park and its environs, in Cauca. In Ecuador, found locally near tree-line, mostly on E slope, in Carchi, W Napo, W Morona-Santiago, Azuay, E Loja and S Zamora-Chinchipe; fairly common in Cajanuma sector of Podocarpus National Park, in Loja. In adjacent part of N Peru, recorded from Cerro Chionguela, in E Piura, S along Piura–Cajamarca border. The scatter of records suggests that this species' distribution is local, although much of the habitat within its range either is not readily accessible to investigators or, where it is accessible, has been subject to extensive deforestation from firewood-cutting, potato cultivation and human settlement. In recent years, it has been found at a number of additional sites in Ecuador but, as yet, at only few sites in Colombia. In both of those countries one of main threats is continued burning of *páramo* grasslands, which ultimately damages and reduces tree-line and ecotone shrubbery favoured by this tanager; in severely damaged areas tree-line has been burnt back and lowered by several hundred metres in elevation. Habitat loss in its SW Colombian range particularly severe, with estimates of no more than 10% of original tree-line habitat remaining; upper montane forest being replaced by exotic pine (*Pinus*) plantations near recently discovered site in Nariño. In addition to Podocarpus National Park, which possibly holds a major proportion of the total population, and Puracé National Park, which is regularly burnt, this species has been recorded in at least five other protected areas, most in Ecuador.

Bibliography. Álvarez-Rebolledo *et al.* (2007), Anon. (2010a), Arbeláez-Cortés & Baena-Tovar (2006), Butchart & Stattersfield (2004), Clements & Shany (2001), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Fjeldså & Krabbe (1990), Hellmayr (1936), Hilty (1985), Hilty & Brown (1986), Isler & Isler (1999), Krabbe *et al.* (2001), Moore (1934b), Parker *et al.* (1985), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sedano & Burns (2010), Stattersfield & Capper (2000), Strewe & Kreft (1999).

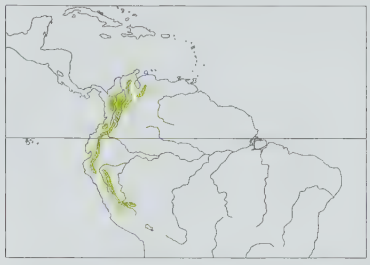
Genus *ANISOGNATHUS* Reichenbach, 1850

86. Santa Marta Mountain-tanager

Anisognathus melanogenys

French: Tangara des Santa Marta **Spanish**: Tangara de Santa Marta
German: Schwarzwangen-Bergtangare
Other common names: Black-cheeked Mountain-tanager

Taxonomy. *Poecilothraupis melanogenys* Salvin and Godman, 1880, near San Sebastian, 8000 feet [c. 2440 m], Santa Marta Mountains, Colombia.
Formerly placed with *A. lacrymosus* and *A. igniventris* in a separate genus, *Poecilothraupis*. May form a superspecies with *A. lacrymosus*, and in the past treated as conspecific. Monotypic.
Distribution. Santa Marta Mts, in N Colombia.



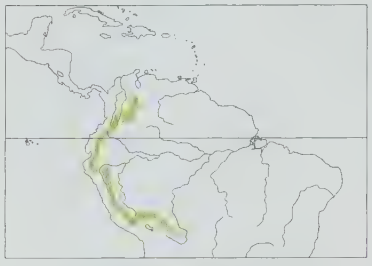
Descriptive notes. 18 cm; 41 g (1 male). Strong-billed tanager with mainly blue-and-yellow plumage. Has crown and nape shining blue, lores, side of head and neck black (not sharply set off from adjacent grey-blue on side of neck), small yellow spot immediately below eye; upperparts dull dark grey-blue, tail dusky, tinged and edged dark blue; lesser and median upperwing-coverts dull dusky blue, greater coverts dusky, obscurely edged and tipped greenish-blue, flight-feathers and tertials dusky, obscurely edged greenish-blue; throat and entire underparts to undertail-coverts golden-yellow, usually with small amount of black mottling visible on sides and flanks; thigh black; iris dark reddish-brown; bill and legs blackish. Differs from similar *A. lacrymosus* in having crown blue and underparts bright yellow. Sexes similar. Juvenile apparently undescribed. Voice. Calls very high-pitched, thin "tic" and "ti" and "ee" notes, sometimes accelerating into trills or rapid bursts of notes.
Habitat. Mossy wet-forest borders, second-growth woodland, and regenerating second growth in pastures; less numerous inside wet montane forest. Found over wider range of habitats than is *A. lacrymosus*. At 1500–3200 m, seasonally as low as 1200 m.
Food and Feeding. Known to take a variety of small fruits, and probably also some insects; no other details of diet available. Occurs in pairs and in varyingly sized groups of up to about six individuals, often at fruiting trees and shrubs; often joins mixed-species flocks. Forages from eye level up to canopy, but most foraging in subcanopy or below. Generally conspicuous; runs and hops along mossy branches and into foliage.
Breeding. Ten breeding-condition birds in Jan–Jun and Sept; one individual seen while building open cup-nest 14 m up in tree. No other information.
Movements. Part of population may shift to lower elevation during peak of rainy season, from Jun through Sept.
Status and Conservation. Not globally threatened. Restricted-range species: present in Santa Marta Mountains EBA. Common within its very small global range. Entire population of this species is limited to montane regions in Santa Marta Mts of N Colombia. Deforestation widespread in much of its range, even within Sierra Nevada de Santa Marta National Park, where it occurs. Readily utilizes various types of second growth and edge habitat, however, and is therefore buffered to some extent from forest losses. Numbers may have declined because of deforestation and human settlement, but at present this species unlikely to face serious risk.
Bibliography. Donegan & Avendaño (2010), Dunning (1982), Fjeldså & Krabbe (1990), Hellmayr (1936), Hilty & Brown (1986), Isler & Isler (1999), Krabbe (2008), Meyer de Schauensee (1964, 1966, 1970a), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sedano & Burns (2010), Sibley & Monroe (1990), Strewe & Navarro (2004), Todd & Carriker (1922).

87. Lacrimose Mountain-tanager

Anisognathus lacrymosus

French: Tangara larmoyant **German**: Tränenbergtangare **Spanish**: Tangara Lacrimosa

Taxonomy. *Tachyphonus lacrymosus* du Bus de Gisignies, 1846, Maraynioc, Peru.
Formerly placed with *A. melanogenys* and *A. igniventris* in a separate genus, *Poecilothraupis*. May form a superspecies with *A. melanogenys*, and in the past treated as conspecific. Nine subspecies recognized.
Subspecies and Distribution.
A. l. pallididorsalis Phelps, Sr & Phelps, Jr, 1952 – Perijá Mts on N Colombia–W Venezuela border.
A. l. melanops (Berlepsch, 1893) – Andes of W Venezuela (in Trujillo, Mérida and N Táchira).
A. l. tamae (Phelps, Sr & Gilliard, 1941) – Andes of W Venezuela (S Táchira) and adjacent E Andes of Colombia (Norte de Santander and Boyacá).
A. l. olivaceiceps (Berlepsch, 1912) – Colombia at N end of W Andes (Antioquia) and in C Andes (S to Quindío and Tolima).
A. l. yariguierum Donegan & Avendaño, 2010 – Colombia on W slope of E Andes in Santander (Serranía de Yaraguíes).
A. l. intensus Meyer de Schauensee, 1951 – SW Colombia on E slope of W Andes (Valle and Cauca).
A. l. palpebrosus (Lafresnaye, 1847) – S Colombia (on both slopes in S Cauca and Nariño) and E slope of Ecuador (S to at least Morona-Santiago).
A. l. caerulescens (Taczanowski & Berlepsch, 1885) – E slope of Andes in Ecuador (from Loja, or possibly farther N) and N Peru (S to Cajamarca and N Amazonas).
A. l. lacrymosus (du Bus de Gisignies, 1846) – E slope in Peru from Amazonas (S of R Marañón) S to Junín, Ayacucho and N Cuzco).



Descriptive notes. 16–17 cm; 25–38 g. Fairly distinctive tanager with rather short and thick bill. Nominate race has crown and upperparts slaty blue, rump slightly more bluish, tail dusky, obscurely edged blue; side of head down to throat and neck dusky, small but prominent pale yellow spot beneath eye (like teardrop); bend of wing and lesser upperwing-coverts shining cornflower-blue (usually concealed), median and greater coverts dusky, edged blue, flight-feathers dusky, narrowly and obscurely edged greenish-blue, tertials dusky, obscurely edged blue; throat and underparts to undertail-coverts ochre-yellow, thigh olive-yellow, sides of chest and upper breast sometimes with some dusky mottling; iris dark brown; bill blackish; legs slate-grey to black. Sexes similar. Juvenile is duller and paler above and duller yellow below than adult, has olive wash on sides. Races differ mainly in colour or tone of upperparts and underparts, also in head pattern, nominate lacking postauricular spot: *intensus* is darker above than nominate, deeper ochre below, has both small yellow spot beneath eye and larger yellow spot on rear ear-coverts; *palpebrosus* is very similar to previous, differs in having flight-feathers edged with bluish (not bluish-green), side of head paler, more greenish-slate, and underparts bright warm yellow; *caerulescens* is intermediate between preceding two, and sometimes lacks yellow spot below eye; *olivaceiceps* differs from *intensus* in slightly paler upperparts, and in distinct olive tinge on side of head, side of neck and side of chest; *pallididorsalis* is distinctive, has forecrown and side of head smoky yellow-olive, crown to back dull bluish-grey (paler than other races), greater wing-coverts slightly paler blue, flight-feathers and tertials narrowly edged paler blue, underparts ochre-yellow, olive mottling on sides and flanks, often lacks yellow spot below eye; *tamae* is like last, but with darker back, olive mottling continuing down sides and flanks, and normally has yellow spot below eye; recently described *yariguierum* differs from preceding two in having darker and bluer crown, darker mantle, darker blue rump and shoulder, and darker face with less strong yellowish tones, also darker tail with less extensive blue; *melanops* is bluer above and golden-yellow to tawny-yellow below, yellower on belly. Voice. Dawn song in Peru, from exposed perch in top of shrub or small tree, 2–6 phrases composed of high, sharp squeaky notes, e.g. "chuck-zit zit, swick-ee-dee-it-it", or "swickee-deee-deee", and so on, frequently the same phrase repeated one to several times; resembles song of *Thraupis cyanocephala*. Possible short song in S Colombia described as an excited "ee-chut-chut-ee", over and over. High thin "see" or "seeek" notes during foraging; also short bursts of staccato chipping (2–8 notes) over and over.
Habitat. Humid and wet montane forest, shrubby forest borders and, at high elevations, stunted mossy forest up to tree-line and locally in patches of woodland and *Polylepis* above tree-line. At c. 2100–3300 m in most areas, 1800–3500 m in Peru, and as high as 3800 m in Colombia; also recorded down to 1800 m in Venezuela.
Food and Feeding. Mostly fruit and insects. Noted as eating berries from melastomes and from *Schefflera* in Peru. Of 17 stomachs examined, 15 contained only vegetable matter and one only animal matter, and one contained both; contents were fruit pulp, seeds and insects. A conspicuous tanager, often notably confiding; regularly pauses to rest quietly in open or semi-open on low or high branch, sometimes remaining there for several minutes. Pairs or small groups habitually associate with fast-moving mixed flocks containing tyrant-flycatchers (Tyrannidae), emberizid finches and other tanagers; also forage away from them, peering around in leisurely manner. Often forages in large bushes and small trees, and also ascends into subcanopy; ranges over large area. Hops rather heavily in foliage, leaning forward to take fruits, and may glean some insects from leaves, petioles, lichen and bark; occasionally sallies awkwardly for flying insects.
Breeding. In Colombia, one nest found in May and begging juvenile in Jul in Cauca (Puracé National Park), and twelve birds in breeding condition in Feb–Aug in Andes. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Fairly common to common; widely distributed in Andes from Venezuela S to S Peru. While deforestation in montane regions has fragmented and reduced the amount of habitat available to it, this species appears not to be faced with any immediate threats. In addition, it is found in many protected areas, including Guaramacal, Sierra Nevada and Tamá National Parks (Venezuela), Los Nevados, Nevado del Huila, Puracé, Paramillo, Las Orquídeas and Farallones de Cali National Parks and Tambito Nature Reserve (Colombia), Cayambe-Coca, Antisana, Podocarpus and Sumaco-Galeras National Parks (Ecuador), and Tingo Maria National Park and Cordillera de Colán Reserve (Peru).

88. Scarlet-bellied Mountain-tanager

Anisognathus igniventris

French: Tangara à ventre rouge **Spanish**: Tangara Ventriescarlata
German: Mennigohr-Bergtangare
Other common names: Black-bellied Mountain-tanager (*lunulatus*)

Taxonomy. *A.[glaia] igniventris* d'Orbigny and Lafresnaye, 1837, Apolobamba, Bolivia.
Formerly placed with *A. melanogenys* and *A. lacrymosus* in a separate genus, *Poecilothraupis*. Four subspecies recognized.
Subspecies and Distribution.
A. i. lunulatus (du Bus de Gisignies, 1839) – Andes of W Venezuela (S Táchira) and adjacent Colombia (Norte de Santander S in E Andes to Cundinamarca).
A. i. erythrotus (Jardine & Selby, 1840) – C Andes of Colombia (Caldas, Cauca, Huila, and both slopes in Nariño) S through Ecuador to N Peru (N of R Marañón, S to R Chamaya).
A. i. ignicrissa (Cabanis, 1873) – E slope of Andes of Peru S of R Marañón (C Cajamarca S of R Chamaya, and from Amazonas S to Junín).
A. i. igniventris (d'Orbigny & Lafresnaye, 1837) – E slope of Peru (from Junín) S to Bolivia (Santa Cruz).
Descriptive notes. 16 cm; 21·5–41 g. Boldly marked tanager with unmistakable colour pattern; bill short and thick. Nominate race has head, throat, chest and upperparts slaty black, mantle and upper

back slightly glossed blue-black, lower back and rump shining blue (conspicuous in flight); tail slaty black; orange-red triangular patch just behind rear ear-coverts; bend of wing and lesser and median upperwing-coverts shining cornflower-blue, rest of wing blackish; breast, sides and upper belly orange-red, band stretching from upper rear flanks down to thighs and vent black, with variable bluish sheen; iris dark brown; bill and legs black. Sexes similar. Juvenile has black of plumage duller and red replaced by dull brownish-orange to dull orange-rufous; older stages have the orange-rufous stained with red. Races differ mainly in coloration or tone of plumage: *erythrotus* differs from nominate in having head to back and down to chest deep black (not slaty), triangular neck patch, breast, sides and upper belly bright red (not orange-red), vent area and undertail-coverts solid black; *lunulatus* differs little from previous, although on average slightly more orange-red, and vent area mixed red and black; *ignicrissa* is intermediate in colour of red areas, with auricular spot, breast, sides and upper belly brighter than nominate but duller than *erythrotus*, and lower underparts mixed red and black. Voice. Sings more than congeners. Song geographically variable; in Venezuela and Colombia frequently at dawn, or at long intervals during the day, a tinkling (like little bells) jumble of rapid, complex, rising and falling notes mixed with lower-pitched nasal notes, somewhat comparable to sound made by cranking of an old engine. Songs of S two races (*ignicrissa* and nominate) differ from those of N birds but also are variable; typically include numerous squeaky, nasal and mechanical-sounding warbles, with many repeated phrases. Sings mostly from exposed perches at dawn, more from concealment during day.

Habitat. Occurs both inside and along borders of montane forest and elfin woodland, also in thick hedgerows, shrubby hillsides, second growth and disturbed or agricultural areas and remnant patches of woodland up to edge of *páramo* and *puna*; occasionally in parks and gardens and green belts in settled areas. All races utilize wide range of habitats, but S ones seem more closely associated with forest, those in N of range more often at forest borders or in semi-open areas, woodlots, and lines of trees and shrubs along fencerows. Mostly at 2600–3500 m; rarely down to 2250 m and up to as high as 3900 m.

Food and Feeding. Eats mostly fruit, also petals or centres from flowers, and nectar; also insects. Of 44 stomachs examined, 41 contained only vegetable matter, one held only animal matter and two contained both; contents were fruit pulp, seeds, leaves, buds, and insects. Occurs in pairs or in loosely associated groups of up to about eight, occasionally more, which forage alone or join mixed flocks of other tanagers and finches in forest or along forest borders. Often seen as it moves in somewhat undulating and usually low flight across openings between hedgerows or forest patches, but once in forest can be difficult to see. Forages from low to high levels, e.g. average foraging height in Bolivia was c. 6 m (mostly in upper third of trees); may sit relatively immobile near top of or in inner part of a tree for a moment, and then hop through foliage. Fruit generally taken by reaching outwards or downwards, without acrobatics. Gulps or mashes fruit; may mash flowers for nectar. In Bolivia, observed obtaining insects by reaching under, hanging down, or sallying 2 m out to air.

Breeding. Fledglings in Feb, Apr and Jun in Colombia, Jan and Jun–Sept in Ecuador, Dec in Peru and Mar in Bolivia; in Colombia, one bird in breeding condition in Nov, three in late Dec, six in Feb and two in Jul. Strongly territorial in Peru. Nest found in trees and thickets in Colombia. Eggs presumed of this species were pale greenish-white with small reddish-brown and violet-grey spots, especially at large end. No other information.

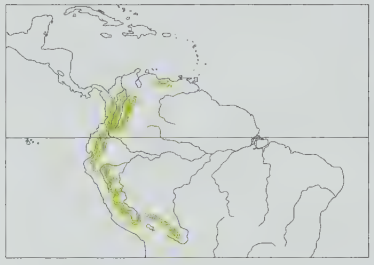
Movements. No local or seasonal movements verified, but wanders widely and regularly appears in parks and other green areas in cities (e.g. on Sabana de Bogotá, in Colombia) if these close to forest. Individuals seen well above or below normal altitudinal range may be wanderers or represent elevational movements.

Status and Conservation. Not globally threatened. Uncommon to locally common. Despite extensive deforestation within parts of its range, this species is able to utilize a broad spectrum of natural and disturbed or man-altered habitats, preventing it from suffering severe impacts from loss of primary forest. Occurs also in numerous parks and other protected areas, as well as unprotected ones, and thrives locally in many heavily intervened areas so long as some woodlots, patches of forest and shrubby fencerows remain. Occurs in Tamá National Park (Venezuela), Sierra Nevada del Cocuy, Chingaza and Puracé National Parks and many others (Colombia), Cayambe-Coca, Sangay and Podocarpus National Parks (Ecuador), Cordillera Azul, Tingo Maria and Manu National Parks (Peru), and Isiboro Sécure and Amboró National Parks (Bolivia).

Bibliography. Álvarez-Rebolledo & Córdoba-Córdoba (2002), Anon. (2000), Barat (1980), David & Gosselin (2002a), Dunning (1982), Fjeldså & Krabbe (1990), Hellmayr (1936), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Krabbe *et al.* (2001), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Moynihan (1979), Ogilvie-Grant (1912), Olivares (1969), Peters & Griswold (1943), Remsen *et al.* (1987), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sedano & Burns (2010), Walker (2001), Zimmer (1944).

89. **Blue-winged Mountain-tanager**

Anisognathus somptuosus



French: Tangara somptueux **German**: Blauflügel-Bergtangare **Spanish**: Tangara Aliazul
Other common names: Blue-shouldered/Blue-rumped Mountain-tanager

Taxonomy. *Tachyphonus somptuosus* Lesson, 1831, no locality = Peru.

This species, *A. flavinucha* and *A. notabilis* were formerly placed in a separate genus, *Compsocoma*. Usually treated as conspecific with *A. flavinucha*, but the two differ markedly in voice and to lesser degree also in plumage; their ranges are believed to be geographically isolated, although approaching each other closely. Present treatment as separate species provisional, pending genetic and further vocal analysis of the various taxa. Race *alamoris* extremely similar to nominate and possibly better synonymized with it; provisionally retained pending thorough review of all races. Eight subspecies currently recognized.

Subspecies and Distribution.

A. s. venezuelanus (Hellmayr, 1913) – N Venezuela (coastal cordillera from Yaracuy E to Miranda).
A. s. viridiidorsalis (Phelps, Sr & Phelps, Jr, 1949) – Aragua (Cerro Golfo Triste), in N Venezuela.
A. s. antioquiae (Berlepsch, 1912) – N end of W Andes, both slopes of C Andes (in Antioquia) and E slope (in Tolima), in N Colombia.
A. s. victorini (Lafresnaye, 1842) – Andes of W Venezuela (S Táchira) and W slope of E Andes of Colombia (from Santander S to head of Magdalena Valley, in Huila).
A. s. cyanopterus (Cabanis, 1866) – Andes of S Colombia (W slope of C range S from Quindío) and W Ecuador (S to Chimborazo and NE Azuay).
A. s. alamoris (Chapman, 1925) – S Ecuador (W slope in S Azuay, El Oro and W Loja).
A. s. baezae (Chapman, 1925) – E slope of Andes in SW Colombia (Nariño) and Ecuador (S to Morona-Santiago).
A. s. somptuosus (Lesson, 1831) – E slope of Andes in extreme S Ecuador (Zamora–Chinchipe) S to C Bolivia (La Paz, Cochabamba).

Descriptive notes. 16–17 cm; 33–56 g (combined weight data from when lumped with *A. flavinucha*). Distinctive strong-billed tanager with mostly blue wings and bold plumage pattern. Nominate race has forehead and side of head to well below eye black, fairly broad yellow stripe from centre of crown to nape (stripe sometimes partly concealed); mantle and back deep black, rump dark brownish-olive becoming greener on uppertail-coverts; tail blackish, at least several outer pairs of feathers edged bright blue; marginal coverts and lesser and median upperwing-coverts shining cobalt-blue, greater coverts black; primary coverts black, flight-feathers black, broadly edged bright turquoise-blue, tertials deep black; throat and entire underparts bright yellow except for black rear thigh, underwing-coverts bright yellow; iris dark reddish-brown; upper mandible blackish, lower mandible bluish-grey with blackish tip and base; legs dark horn-grey. Differs from similar *A. notabilis* mainly in much darker, black mantle and back. Sexes similar. Juvenile has yellow in plumage duller. Races vary mainly in colour and pattern of upperparts: *baezae* differs from nominate in having back and rump mixed black and olive; *alamoris* is very like nominate (with same turquoise-blue flight-feather edging), but perhaps slightly smaller and with upperparts slightly tinged green; *cyanopterus* is much like nominate, but rump dark olive-green (not dark brownish-olive) and wing edgings darker cobalt-blue (not bright turquoise-blue); *victorini* is slightly larger, and has mantle to uppertail-coverts moss-green; *antioquiae* has centre of mantle and back tinged greenish, rump green, wing and tail edged medium blue; *viridiidorsalis* differs in having back greenish-black, flight-feathers edged cobalt-blue like shoulder (not bright turquoise-blue), and tail feathers edged cobalt-blue; *venezuelanus* differs from nominate in slightly smaller size, back sooty black (duller than nominate), and lower rump and uppertail-coverts sooty black with yellowish-green tinge. Voice. Generally rather quiet. Song a weak, rapid, very high-pitched, almost twittering "ti-ti-ti-ti ti'ti'ti'ti'ti'titi'ti'ti'ti'ti'ti ti ti", a little louder and faster in middle, in N & C Peru described as a high, weak wheedling "si-titi-si-titi tsu-ti-su-ti-tsu-ti-tsu-ti"; very unlike song of *A. flavinucha*. When foraging, gives soft "tic" and "teep" notes, or short bursts of "tic" notes, sometimes extended into little trills.

Habitat. Humid and wet forest, forest borders, and tall second-growth woodland. At 900–2100 m in Venezuela, mostly 1400–2600 m in Colombia, and 1200–2500 m in Ecuador.

Food and Feeding. Insects, and small fruits and berries. Conspicuous pairs or groups of 3–10 individuals forage alone or join mixed-species flocks typically containing other tanagers as well as New World warblers (Parulidae), but frequently strike out on their own in unpredictable or erratic little forays. Forages at various heights, from below eye level to (occasionally) high in canopy, and inside or at edge of forest; median foraging height in Valle (Colombia) was c. 12 m. Energetic, foraging actively in distinctive, stereotyped manner, nimbly run-hopping along slender, mostly bare branches, working out fairly quickly to terminal foliage clusters, where it pauses or hops deliberately and spends up to 30 seconds in peering around carefully, stretching up, leaning down, and occasionally pecking or lunging short distance for prey, sometimes sallying or hovering; then flies to another branch and repeats process. Also regularly checks hanging dead leaves for insects. Takes *Miconia* berries mostly without acrobatics.

Breeding. In Colombia, nests in Apr–Jun in SW (La Planada Nature Reserve), nestlings in Jun and fledglings in Nov in Valle del Cauca, and juveniles in Mar and Sept–Oct, and three breeding-condition birds in Mar and 17 more May–Sept in N; in Ecuador, juveniles in Jan in S and adult carrying nest material in early Mar in SW (Tambo Negro, in Loja, 600–1000 m); juveniles in Mar in Peru. Co-operative breeding, with four adult helpers, recorded in Colombia. At La Planada (Colombia), nest an open cup 12·4 cm in diameter and 8·6 cm high, made from soft plant material including rootlets, green moss, fern leaves and fine vegetable fibres, lined with finer moss and dry bamboo leaves, one placed 3·5 m up on horizontal limb of pepper (*Piper*) covered with tree-fern leaves and bamboo at disturbed forest border, another 6·5 m up on horizontal branch of *Clusia*, and a third 7·5 m up; in captivity, cup-nest of coarse grass and lined with finer grass. Following details taken from S Colombia (La Planada): at one nest one dominant individual (possibly female) and four adult helpers were present, helpers fed dominant bird, which in turn fed the two nestlings, as also did helpers, two fledglings subsequently seen with the five adults c. 50 m from nest tree and all seven remained together for c. 7 months or possibly more; at a second nest, one bird incubated and four helpers present; a third nest was attended by only two adults, which were seen to carry food to nest.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Fairly common, and widespread across most of its large Andean range. Locally may occur at low density. Present in many protected areas, e.g. Henri Pittier, Guaramacal, Sierra Nevada and Tamá National Parks (Venezuela), Chingaza, Cueva de los Guácharos, Nevado del Huila, Puracé, Las Orquídeas, Farallones de Cali and Munchique National Parks anmd La Planada and Tambito Nature Reserves (Colombia), Sangay, Cayambe-Coca and Podocarpus National Parks (Ecuador), and Cordillera Azul and Tingo Maria National Parks (Peru). Occurs also in many unprotected areas with suitable habitat. Andean deforestation has resulted in local range contraction and fragmentation.

90. **Bolivian Mountain-tanager**

Anisognathus flavinucha

French: Tangara à nuque jaune **Spanish**: Tangara Boliviana
German: Blauschwingen-Bergtangare

Taxonomy. *T.*[*achyphonus*] *flavinucha* d'Orbigny and Lafresnaye, 1837, Yungas, Bolivia.
This species, *A. somptuosus* and *A. notabilis* were formerly placed in a separate genus, *Compsocoma*. Usually treated as conspecific with *A. somptuosus*, but the two differ markedly in voice and to lesser degree in plumage; their ranges are believed to be geographically isolated, although approaching each other closely. Present treatment as separate species provisional, pending genetic and further vocal analysis of the various taxa. Monotypic.
Distribution. E slope of Andes in Peru (from Puno) S to S Bolivia (Chuquisaca).

Descriptive notes. 16–17 cm; 33–56 g (combined weight data from when lumped with *A. somptuosus*). Has head, throat, mantle and back deep black, prominent bright yellow median crownstripe on hindcrown and nape; lower back and rump bright cobalt-blue; lesser and median upperwing-coverts purplish-blue, greater coverts black, primary coverts, flight-feathers and tail black, feathers sharply edged pale turquoise-blue, tertials mostly black; underparts bright golden yellow; iris dark brown; bill black, base of lower mandible blue-grey; legs dark grey. Differs from very similar *A. somptuosus* mainly in having more restricted yellow crownstripe, and cobalt-blue (not olive) rump. Sexes similar. Juvenile is much like adult, but duller yellow below, with yellow feathers of rear crown and nape mixed or tipped with black. Voice. Frequently heard song, at dawn and in morning hours, while perched or in flight display as bird climbs 30–45 m on shallowly beating wings, a series of musical whistles, soft but gradually increasing in volume and pitch, e.g. "too-too tyoo-towoo-towoo too-wít too-wít too-wít", rather loud at end; in S Peru described as a rising series of wiry, quavering notes, "tchu-tchu-twéé-aww twéé-awéé wéé-wéé wéé-wéé"; dramatically different from song of *A. somptuosus*. Calls are high "tic" notes.
Habitat. Humid and wet montane forest, forest borders and older second growth, generally not away from taller forest. At c. 1500–2500 m.
Food and Feeding. Insects and fruit; takes large melastome fruits. Forages mainly in middle levels up to canopy; sometimes descends into shrubbery in undergrowth of forest or along forest edges. Hops along mossy epiphyte-covered branches away from leaves, and searches moss and bark. Behaviour much like that of *A. somptuosus*.
Breeding. In Bolivia, bird in breeding condition reported in Aug and eggs in Oct in La Paz, and fledglings in Apr in Cochabamba. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Range much smaller than that of allied *A. somptuosus*, but montane habitat in S Peru and adjacent Bolivia remains in relatively good shape. Occurs in several large protected areas, including Manu National Park, in Peru, and Madidi, Isiboro Sécure and Amboró National Parks, in Bolivia.
Bibliography. Bleiweiss (2004), Clements & Shany (2001), Fjeldså & Krabbe (1990), Hesse (1980a), Isler & Isler (1999), Krabbe & Nilsson (2003), Mayer (2000), Norgaard-Olesen (1973), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Weske (1972), Zimmer (1944).

91. Black-chinned Mountain-tanager

Anisognathus notabilis

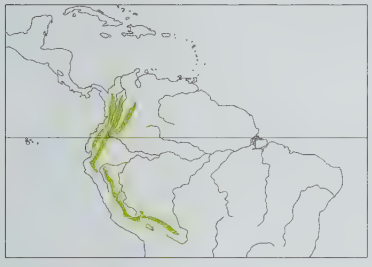
French: Tangara à menton noir **Spanish**: Tangara Barbinegra
German: Schwarzkinn-Bergtangare

Taxonomy. *Tanagra notabilis* P. L. Sclater, 1855, eastern range of cordilleras north of Quito, Ecuador.
This species, *A. somptuosus* and *A. flavinucha* were formerly placed in a separate genus, *Compsocoma*. Monotypic.
Distribution. W Andes of Colombia (Pacific slope from headwaters of R San Juan, in Risaralda) S to W Ecuador (El Oro and W Loja).

Descriptive notes. 18 cm; one male 44·1 g, one female 68·5 g. Quiet tanager with svelte plumage and fairly strong and rather pointed bill. Has forecrown, side of head, nape and chin black, broad median stripe on rear crown bright yellow; upperparts bright yellow-olive, becoming olive-yellow on rump; tail entirely black (or feathers very obscurely edged dark violet-blue); lesser and median upperwing-coverts plain olive, greater coverts blackish, broadly edged violet-blue, flight-feathers black, narrowly edged dark violet-blue, tertials black, narrowly edged violet-blue; central throat and underparts, including undertail-coverts, rich orange-yellow, underwing-coverts bright yellow; iris dark red; bill black, bluish-grey on base of lower mandible; legs black. Distinguished from *A. somptuosus* mainly by olive (not black) back, less conspicuous wing edgings and richer orange (not yellow) underparts. Sexes similar. Juvenile apparently undescribed. Voice. Not particularly vocal, even when foraging. Infrequently heard song a series of high-pitched notes, "tsit-tsit-tseeéu-tsit-tseeu-tsit", repeated over and over; calls high thin "tic" notes.
Habitat. Humid and wet mossy forest and forest borders. At 900–2200 m (once to 300 m) in Colombia; mostly 1400–2200 m in Ecuador, but in El Oro as low as 800–1100 m.
Food and Feeding. Fruit; presumably also insects. Nestlings in Colombia were fed with relatively large flying insects, including beetles (*Coleoptera*), hymenopterans and lepidopterans, and fruits (*Alchornea*, *Clusia* and *Miconia* identified). Usually seen singly or in pairs, much less often in groups up to six individuals; singles, pairs or groups often forage with mixed-species flocks. May sit more or less still and rather erect, then briskly run-hop along branches and peer at foliage or fruit at various heights, from fairly low along wooded borders to much higher in taller forest. During brood-feeding period, captures many insects in air in short hawking manoeuvres, 5–20 m from branches. Generally less conspicuous than *A. somptuosus*, although the two are sometimes found together.
Breeding. In SW Colombia, three nests found during 10th Apr and 5th May at La Planada Nature Reserve (in Nariño); following details refer to these. Nest constructed within clump of moss and epiphytes 13·4–16·5 m above ground on tree limb in undisturbed wet, epiphyte-laden montane forest on ridge (at 1740–1780 m). First nest attended by three adults, all carrying food to nestlings (insects captured generally within c. 50 m of nest tree); after this nest failed, one observed carrying moss and dry leaves to new site, and by end May all three were again feeding young; seven days later, three fledglings seen near nest-site; inferred incubation period c. 12–14 days and nestling period c. 13–15 days. No breeding-territory overlap with *A. somptuosus*, which favoured forest-edge sites.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Uncommon to locally fairly common in Ecuador; generally less numerous and more local in Colombia. In general less numerous and less conspicuous than *A. somptuosus*. Deforestation, various farming activities and illegal cultivation of coca and marijuana within this species' range (especially in SW Colombia) are ongoing threats within the rather narrow elevational band of Pacific-slope montane forest where it occurs. Present in several protected areas, including Farallones de Cali and Munchique National Parks and La Planada, Tambito and El Pangan Nature Reserves (Colombia), and El Angel and Cotocachi-Cayapas Ecological Reserves and Maquipucuna Reserve (W Ecuador). Although populations trends for this species have not been quantified, it is almost certainly declining.
Bibliography. Bleiweiss (2004), Donegan & Dávalos (1999), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Moore *et al.* (1999), Orejuela & Cantillo (1990), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sedano & Burns (2010), Strewe (2001a, 2001b).

PLATE 10

inches 3



Genus *CHLORORNIS* Reichenbach, 1850

92. Grass-green Tanager

Chlorornis riefferii

French: Tangara de Rieffer **German**: Papageitangare **Spanish**: Tangara Lorito

Taxonomy. *Tanagra Riefferii* Boissonneau, 1840, Santa Fé de Bogotá, Colombia.
Molecular-genetic studies place present species within *Buthraupis*, most closely related to *B. eximia* and *B. aureodorsalis*. Five subspecies recognized.
Subspecies and Distribution.
C. r. riefferii (Boissonneau, 1840) – Andes of Colombia and Ecuador.
C. r. dilutus J. T. Zimmer, 1947 – Andes of N Peru S of Chachapoyas.
C. r. elegans (Tschudi, 1844) – Andes of C Peru (Junín).
C. r. celatus J. T. Zimmer, 1947 – Andes of S Peru below Limbani.
C. r. bolivianus (Berlepsch, 1912) – Andes of Bolivia (La Paz).

Descriptive notes. 20 cm; 42–59 g. Large, unmistakable tanager with grass-green plumage, robust proportions and orange bare parts; bill thick and somewhat conical. Nominate race is bright shining green, with narrow area of chestnut on base of forehead, lores, ocular area, cheek and chin (forming conspicuous mask); bend of wing and marginal coverts pale blue (almost always hidden), otherwise upperwing-coverts green, primary coverts dusky, edged green, flight-feathers dusky, heavily edged green, tertials dusky, broadly edged green; undertail-coverts chestnut; iris chestnut-brown; bill bright orange; legs bright orange, claws dusky orange. Sexes similar. Juvenile is much like adult, but duller green and with bill dusky. Races differ relatively little: *boliviamus* is lighter and brighter green than nominate, has larger chestnut mask extending across entire forehead, side of head and most of throat; *dilutus* has blue forehead (inconspicuous) and paler chestnut on face; *celatus* has chestnut of forehead narrowly edged pale blue above; *elegans* is like last, but with chestnut of chin extending to upper throat. Voice. Dawn song 1–2 "enk" notes followed by bursts of 1–5 harsh, squeaky, doubled notes like sound of squeaky gate being rapidly moved. Possible day song a heavy "chink-zheet", second note higher, repeated once every 2 seconds. Most frequently heard vocalization is contact call during foraging, a rather low-pitched, nasal, strained "eenk" or "eek", not loud, notes given singly, paired or sometimes several times in irregular series; infrequently in long stuttering and louder series, especially just prior to or during flight, e.g. "t-e-e-e-e-e-k".
Habitat. Wet, mossy and often rather low-stature or stunted upper montane forest and forest borders almost to tree-line; occasionally dense, mossy second growth. Recorded at c. 1500–3500 m; 1700–3300 m (mostly 2400–2700 m) in Colombia, mostly 2000–2900 m in Ecuador, and at 2000–3500 m in Peru.
Food and Feeding. Of seven stomachs examined, three contained only vegetable matter and two only animal matter, and two held both; contents included fruit pulp, berries, seeds, a 40-mm worm, insect remains and caterpillars. Usually seen in pairs or in small groups of 3–6 individuals, less frequently up to ten; in Bolivia (where apparently less numerous), more often seen singly or in pairs. Regularly forages with mixed-species flocks, then moving sluggishly from branch to branch. Inspects moss and epiphytes with peering movements and, especially, by bending or leaning down to look at mossy sides or undersurfaces of branches 3–6 cm in diameter; may hang head downwards or flutter heavily in foliage.
Breeding. Nests found in Jul and Sept in Ecuador. One nest in Colombia was relatively large, constructed from green moss and decorated with ferns; contained 1 egg, grey, freckled lilac-grey. In Ecuador, two nests in consecutive years in Pichincha (near Tandayapa, at 2250 m), second one only 2 m away from first, believed built by same pair, made from moss, ferns and fine rootlets, lined with tree-fern scales, placed beneath moss on steep roadside bank; 1 egg. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Fairly common throughout most of range; rather uncommon in Bolivia. Present in a number of protected areas, including Las Orquideas, Farallones de Cali, Munchique, Puracé, Cueva de los Guácharos and Chingaza National Parks and Tambito Nature Reserve (Colombia), Sangay and Podocarpus National Parks (Ecuador), Manu National Park (Peru) and Madidi National Park (Bolivia). Considerable intact but unprotected forest remains within this species' high-elevation range, but in many areas it is subject to firewood-cutting, and to deforestation for expanding pastureland for cattle, various agricultural crops, and human settlement.

Genus *DUBUSIA* Bonaparte, 1850

93. Buff-breasted Mountain-tanager

Dubusia taeniata

French: Tangara à poitrine fauve **German**: Silberbrauen-Bergtangare **Spanish**: Tangara Pechifulva
Other common names: Carriker's Mountain-tanager (*carrikeri*)

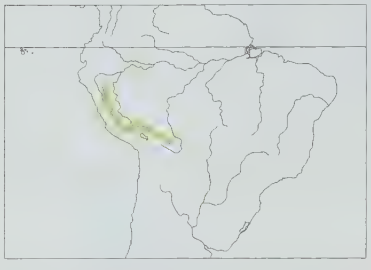
Taxonomy. *Tanagra* (*Tachyphonus*) *taeniata* Boissonneau, 1840, Santa Fé de Bogotá, Colombia.
Molecular-genetic data indicate that this genus and *Delothraupis* are sister-taxa, with *Calochaetes* sister to both. Races have in the past been treated as three separate species. It was recently proposed that S race *stictocephala* be regarded as a separate species (*carrikeri* retained with nominate race), on grounds of known vocal and morphological evidence; this merits further examination. Three subspecies currently recognized.
Subspecies and Distribution.
D. t. carrikeri Wetmore, 1946 – Santa Marta Mts, in N Colombia.
D. t. taeniata (Boissonneau, 1840) – Andes of Venezuela (Trujillo S to Táchira), all three ranges in Colombia (in W Andes mainly N & S ends, in Antioquia and Cauca), and both slopes in Ecuador and NW Peru (S to Piura and N Cajamarca N of Marañón Valley).
D. t. stictocephala Berlepsch & Stolzmann, 1894 – E slope of Andes in Peru (from S side of Marañón Valley, in Amazonas, S to N end of Cordillera Vilcanota, in Cuzco).

Descriptive notes. 20 cm; 31–45 g. Colourful, sturdy-billed, somewhat retiring tanager often noted first through its distinctive voice. Nominate race has head to nape, upper mantle and foreneck black, feathers of forecrown and superciliary area tipped silvery blue, forming long, broad and rather loosely defined frosty supercilium extending almost to nape and often partly down side of neck; most of mantle to rump dark dusky blue, tail blackish, tinged dark blue; lesser upperwing-coverts broadly edged silvery blue, median and greater coverts dusky, broadly tipped slightly darker blue, greater coverts also broadly edged pale greyish violet-blue; flight-feathers and tertials dusky, broadly edged dull blue, flight-feathers narrowly edged dull blue, tertials more broadly edged dull blue; broad pectoral band buff, varying in intensity from whitish-buff to greyish-buff, lower breast and belly bright yellow, thigh dusky blue, undertail-coverts buff; iris dark reddish-brown; bill black; legs blackish. Sexes similar. Juvenile has dull olive-green back and chest, vent area duller and more ochraceous rather than buff. Race *carrikeri* is much like nominate, but forecrown and eyebrow more densely streaked, chin mixed and streaked black and buff, darker buff colour on chest and extending up to centre of throat, and breastband slightly darker, more cinnamon-buff; *stictocephala* has entire crown and nape somewhat streaked and frosted with silvery blue-white, mantle dark blue (like back), buff breastband narrower, and vent and undertail-coverts yellow (not buff). Voice. Song of nominate race and *carrikeri*, repeated over and over at short intervals early in morning, a loud, whistled "phéééé-baay" delivered slowly, second note lower, or downslurred, occasionally expanded to 3 notes, e.g. "téééé teeee tyyyy". In S Peru (*stictocephala*) a thin, high-pitched, single-note whistle sharply slurred downwards, reminiscent of song of a *Pipreola* fruiteater; this single-note song also may be continually repeated at dawn, and sometimes later in morning. May sing from exposed medium-height perch, but more often when partly concealed in vegetation, or at edge of concealing vegetation.
Habitat. Thick, mossy, wet montane forest and broken forest with dense lower vegetation, especially with *Chusquea* bamboo thickets, and dense tangles inside forest and in gaps and edges; locally up to elfin woodland at tree-line and in patches of *Polylepis* and shrubs slightly above tree-line. At 2000–3000 m in Venezuela, 2400–3600 m in Colombia, 2500–3500 m in Ecuador, and 1900–3500 m in Peru; in all areas except Venezuela, most numerous above c. 2500 m.
Food and Feeding. Small fruits and berries, including mistletoe (Loranthaceae), and insects. Three stomachs contained both vegetable and animal matter, including fruit, seeds and insects. Single individuals or pairs, usually heard before they are seen, follow mixed-species flocks or wander alone over large areas. Rather slow-moving; forages from eye level to treetops, but more often fairly low, and often in dense vegetation, where it keeps out of sight. Usually remains at least partially concealed in foliage, but occasionally sits up in the open on top of bush for a few moments. Searches mossy branches for insects. Hops along large limbs, scans upper surfaces, and bends down to look under limbs or in moss, bark and especially lichens; also observed when searching moss on steep banks.
Breeding. Juveniles and immatures in Jan and Sept in NW Ecuador; in Colombia, two breeding-condition birds in late Dec in Boyacá, and a further eight in Feb–Sept in Santa Marta Mts and E & C Andes. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Fairly common almost throughout its range, and widespread. Appears to require fairly large tracts of humid montane forest; has declined or disappeared locally in the face of deforestation, firewood-cutting and human settlement. Can be found in many national parks and other protected areas throughout its range. In addition, extensive unprotected but intact habitat exists within its range, and most of this appears secure at present.
Bibliography. Álvarez-Rebolledo & Córdoba-Córdoba (2002), Burns (1997a), Burns & Naoki (2004), Burns *et al.* (2003), Donegan & Dávalos (1999), Dunning (1982), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Krabbe, Flórez *et al.* (2006), Krabbe, Moore *et al.* (2001), Meyer de Schauensee (1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Olivares (1963), Parker & O'Neill (1980), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sedano & Burns (2010), Walker (2001), Weske (1972), Zimmer (1944).

Genus *DELOTHRAUPIS* P. L. Sclater, 1886

94. Chestnut-bellied Mountain-tanager

Delothraupis castaneoventris



French: Tangara à ventre marron **Spanish**: Tangara Ventricastaña
German: Braunbauch-Bergtangare

Taxonomy. *Calliste castaneoventris* P. L. Sclater, 1851, Bolivia.

On following pages: 95. Diademed Tanager (*Stephanophorus diadematus*); 96. Purplish-mantled Tanager (*Iridosornis porphyrocephalus*); 97. Yellow-throated Tanager (*Iridosornis analis*); 98. Golden-collared Tanager (*Iridosornis jelskii*); 99. Golden-crowned Tanager (*Iridosornis rufivertex*); 100. Yellow-scarfed Tanager (*Iridosornis reinhardti*); 101. Fawn-breasted Tanager (*Pipraeidea melanonota*); 102. Glistening-green Tanager (*Chlorochrysa phoenicotis*); 103. Orange-eared Tanager (*Chlorochrysa calliparaea*); 104. Multicolored Tanager (*Chlorochrysa nitidissima*).

Molecular-genetic data indicate that this genus and *Dubusia* are sister-taxa. Species is sometimes placed in latter genus, in part because their songs are somewhat similar to each other. Birds from Auquimarca (Junin), in Peru, described as a geographical race, *peruviana*, but appear to differ little, if at all, from those in rest of species' range. Treated as monotypic.

Distribution. E slope of Andes in Peru (from SE La Libertad) S to Bolivia (La Paz and Cochabamba).

Descriptive notes. 15 cm; 25–33 g. A small tanager, mainly dull blue above and rufous below, with small bill. Has crown medium sky-blue with slight frosty sheen (pale feather edges), bordered below by narrow black mask from base of forehead and lores back through eye, mask separated from narrow black submalar line by pale malar line mixed rufous and white; upperparts, including uppertail-coverts, rich dark blue, upperwing-coverts dusky, broadly edged and tipped medium blue, flight-feathers, tertials and tail black, edged medium blue; chin whitish, throat and underparts, including undertail-coverts, rufous; iris red to dark red; bill black, basal portion of lower mandible blue-grey; legs blackish. Sexes similar. Juvenile apparently undescribed. Voice. In general not a persistent singer. Song in Peru a clear, whistled "peee paay"; in Bolivia (possibly also Peru) extended to 3 notes, "peeee pee pay" or "pee pee pay", first note highest, and song may be repeated at short intervals early in morning. Both 2-note and 3-note songs recall those of *Dubusia taeniata*, but not so loud or forceful. Also a sharp, high-pitched and slightly descending "tzeeeeee", possibly also song. Call a brief "zee zee", like that of many other tanagers.

Habitat. Dense humid and wet montane forest, elfin woodland, thickets, and gaps and borders in broken montane forest, and patches of scrubby vegetation at tree-line. Recorded mainly at 2000–3500 m in Peru, seasonally down to at least 1650 m in Cuzco (S Peru) and in Bolivia.

Food and Feeding. Arthropods and berries. Normally found singly or in pairs, infrequently three or occasionally more individuals, alone or, more often, with large mixed-species flocks containing tyrant-flycatchers (Tyrannidae), New World warblers (Parulidae) and other tanagers. Stays mostly in canopy or upper levels, occasionally descending to eye level, even near ground along dense forest borders; median foraging height in Bolivia was c. 10 m, or 2·5 m below top of canopy. Takes berries from a perched position. Searches for insects while hopping in rather deliberate manner along large, moss-covered branches. Takes most insect prey from moss; leans head downwards and occasionally hangs upside-down to probe mossy undersides of branches; also picks prey from both surfaces of leaves and from petioles, and has been noted as sallying to air for small flying insects.

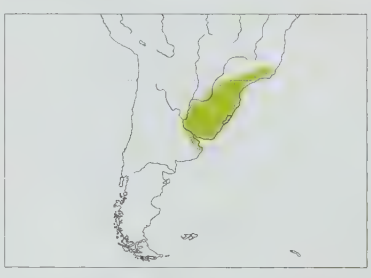
Breeding. No information.

Movements. Local or seasonal movements believed likely, although none reported.

Status and Conservation. Not globally threatened. Uncommon. Distributed along montane and tree-line Andean habitats from N Peru S to C Bolivia. Occurs in various protected areas, including Tingo Maria and Manu National Parks (Peru) and Madidi and Amboró National Parks (Bolivia). Main threats to its habitat are deforestation and firewood-cutting, similar to threats faced by many other montane species. Its range also includes considerable intact, unprotected habitat which appears to be at relatively little short-term risk.

Bibliography. Burns (1997a), Burns & Naoki (2004), Burns *et al.* (2002, 2003), Fjeldså & Krabbe (1990), George (1964), Hilty (2009b), Isler & Isler (1999), Klicka *et al.* (2007), Meyer de Schauensee (1966, 1970a), Parker & O'Neill (1980), de la Peña & Rumboll (1998), Remsen (1984), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Sedano & Burns (2010), Walker (2001), Zimmer (1944).

Genus *STEPHANOPHORUS* Strickland, 1841



95. Diademed Tanager

Stephanophorus diadematus

French: Tangara à diadème **German**: Diademtangare **Spanish**: Tangara Diademada
Other common names: White-capped Tanager!

Taxonomy. *Tanagra diademata* Temminck, 1823, Curitiba, Paraná, Brazil.
Monotypic.

Distribution. SE Brazil (Paraná and São Paulo E to S Minas Gerais and Rio de Janeiro, S to Rio Grande do Sul), adjacent E Paraguay, Uruguay and NE Argentina (E from extreme E Santa Fe, S to N Buenos Aires).

Descriptive notes. 19 cm; two males 35 g and 41·5 g. Rather robust tanager, colourful in good light but most often appearing blackish, with pale crown patch, feathers of forecrown short, dense and plushy; bill short and thick. Has forecrown, lores, ocular area and chin black, forming small mask; large white crown patch surmounted by small but fairly conspicuous red tuft at front (both white and red feathers can be erected); rest of plumage mostly shining dark blue, upperwing-coverts, flight-feathers and tail feathers blackish with heavy dark blue edges (blue edging inconspicuous); iris dark brown; bill blackish; legs dusky grey. Sexes similar. Immature is much duller and duskier than adult, with features of crown obscure. Voice. Dawn song, from high tree limb or treetop, a short, warbled "tio turri, weri tweee", second and third notes lower in pitch, repeated over and over every 3–4 seconds. Day song a loud, rich series of musical notes, like that of a *Pheucticus* grosbeak but with emphatic upslurred note at end and with longer pauses between songs. A countersong, perhaps by female, a sliding whistle followed by two softer short low whistles. Calls include soft, high "chewp", singly or doubled.

Habitat. Variety of wooded to semi-open habitats, including *Araucaria* forest, dense low forest (*monte*), patches of shrubbery around marshes, riverine woodland (especially *Celtis* in Argentine coastal areas), and trees and bushes in parks and gardens. Restricted to mountainous regions in Rio de Janeiro, where most numerous at uppermost elevations, and to tree-line at 2400 m on Mt Itatiaia; otherwise mainly in lowlands.

Food and Feeding. Much fruit, also flowers, buds and some insects; consumes sweet secretions of plant lice. In Rio Grande do Sul (Brazil) reported as eating nine species of fruit, including figs (*Ficus*), Japanese persimmons (*Diospyros kaki*) and papaya (*Carica papaya*). One stomach contained moyé berries (probably *Schinus* species). Found in pairs and in small groups, individuals often perched rather prominently in the open atop shrubbery, but quick to dive into cover when alarmed. In wooded areas regularly occurs with mixed-species flocks and will forage at almost any height, from low down to fairly high in vegetation. In Brazil appeared to glean from leaf surfaces.

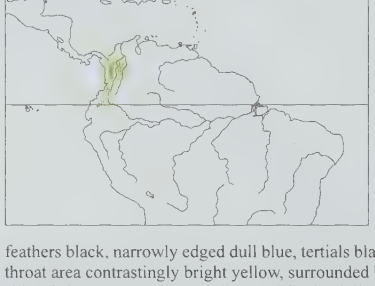
Breeding. Breeding reported in Oct in Rio Grande do Sul (Brazil). Builds a shallow nest 3–4 m up in tree or shrubs. Clutch 4 eggs, white or bluish-white, spotted deep red or purplish-grey, some eggs having black scrawls. No other information.

Movements. Reported as rather sedentary. Possibly migratory in S Uruguay and Argentina.

Status and Conservation. Not globally threatened. Fairly common in SE Brazil (from Itatiaia National Park S to Rio Grande do Sul); fairly common in Uruguay; decidedly local within most of its Argentine range. In coastal mountains of SE Brazil, where deforestation extensive, this species is largely confined to the numerous parks and reserves, among them Itatiaia, Serra dos Órgãos and Aparados da Serra National Parks. In Argentina found in Iguazú, El Palmar and Mar del Plata National Parks, as well as locally in gardens and small reserves along coast to S of city of Buenos Aires.

Bibliography. Aplin (1894), Belton (1985), Burns & Racicot (2009), Descourtilz (1852), Di Giacomo (2009), Diamond & Lovejoy (1985), Frisch & Frisch (1964), Holt (1928), Hudson (1870), Isler & Isler (1999), Meyer de Schauensee (1966), Narosky & Yzurieta (1987), Ogilvie-Grant (1912), Parker & Goerck (1997), de la Peña & Rumboll (1998), Ridgely & Tudor (1989, 2009), Santos (1948), Sclater & Hudson (1888), Sedano & Burns (2010), Sick (1985, 1993), Souza (2002), Straneck (1990), Vigil (1973), Voss & Sander (1980, 1981), Wetmore (1926).

Genus *IRIDOSORNIS* Lesson, 1844



96. Purplish-mantled Tanager

Iridosornis porphyrocephalus

French: Tangara à cape bleue **German**: Purpurmanteltangare **Spanish**: Tangara Capiazul

Taxonomy. *Iridornis porphyrocephala* P. L. Sclater, 1856, neighbourhood of Quito, Ecuador.
Has been considered to form a superspecies with *I. analis*, and sometimes treated as conspecific; evidence for treatment as two separate species is weak, and sympatry not proven. Monotypic.

Distribution. Colombia (entire W slope and very locally on E slope of W Andes, also W slope of C Andes in Antioquia) S to NW Ecuador (Carchi, Imbabura and NW Pichincha).

Descriptive notes. 14 cm; three males 20·3–23 g, one female 21·5 g. Unmistakable tanager, mostly dark blue with yellow throat, and short thick bill. Has base of forehead, lores and ocular area deep black and ear-coverts blackish, somewhat glossed dark purple, forming mask (looks blackish in most lights and does not contrast strongly with rest of plumage); crown, side of head, mantle and back intense dark purplish-blue, becoming slightly paler bluish-green on rump (can look greenish in some lights); tail mainly dusky, rather obscurely edged and tinged dark blue; upperwing-coverts black, broadly and sharply edged dull blue, flight-feathers black, narrowly edged dull blue, tertials black, broadly edged all around with dull blue; wide throat area contrastingly bright yellow, surrounded by dusky purplish-blue that extends to breast and side of chest; central breast, sides and flanks duller and paler blue, sometimes with brownish tinge, centre of lower breast and belly buff, becoming chestnut on undertail-coverts; iris reddish-brown; upper mandible black, lower mandible bluish-grey; legs dark brownish-grey. Sexes similar. Juvenile undescribed. Voice. Calls (in Colombia) include high, slightly raspy "tsit", sometimes accelerating into trill. Possible song a lisping, buzzy "seeeeéeu", c. 1 second long, rising and, at end, falling. Also gives longer "ts-ts-tseéeuit" tseeuwee", which may be a song or a song variation.

Habitat. Very wet mossy forest, tall second growth, and along openings or borders in forest; a few records from less humid areas. Mostly at 1500–2200 m; locally down to 750 m in Cauca and up to 2700 m in Antioquia (above Medellin), in Colombia; in Ecuador mostly c. 1200 m or somewhat higher, but few records.

Food and Feeding. Berries and insects. Single individuals, pairs or families follow mixed tanager flocks or forage alone, 2–10 m up inside or at edge of forest; usually keep mostly out of sight in shrubbery. Does not gather at fruiting trees with other frugivores. Moves more slowly and forages more methodically than do *Tangara* tanagers, often sitting quietly for a few moments or spending 30 seconds to a minute at a location before moving. Hops and peers in dense foliage.

Breeding. In Colombia, begging young with two adults in Jul in Cauca (Cerro Munchique) and nine breeding-condition birds in May–Jun at N end of W & C Andes. No other information.

Movements. Presumed resident. The records at unusually high and low elevations in Cauca and Antioquia, in Colombia, may involve wandering individuals.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Chocó EBA. Rare to locally fairly common in Colombia; very rare in Ecuador. In Colombia, may be rare or locally extirpated from portions of its range at N end of C Andes and N portion of W Andes; no recent records from Antioquia. In Ecuador, only a few scattered records in N; in addition, a specimen apparently from S Ecuador but of uncertain locality, possibly from Cañar, along Guayaquil–Quito railway. Deforestation, farming activities and illegal cultivation of coca and marijuana within this species' range (especially in SW Colombia) are ongoing threats within the narrow elevational band on Pacific-slope montane forest where it lives. Occurs in several protected areas, including Tatamá, Farallones de Cali and Munchique National Parks and Tambito and El Pangan Nature Reserves, in Colombia; not known to occur in any reserves or protected areas in Ecuador.

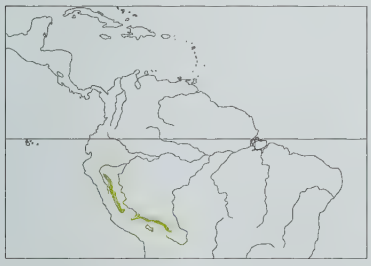
Bibliography. Álvarez-Rebolledo *et al.* (2007), Anon. (2010a), Butchart & Stattersfield (2004), Chapman (1926), David & Gosselin (2002b), Donegan & Dávalos (1999), Dunning (1982), Fjeldså & Krabbe (1990), Hellmayr (1936), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1964, 1966, 1970a), Moore *et al.* (1999), Orcés (1944), Orejuela & Cantillo (1990), Remsen *et al.* (2010), Renjifo *et al.* (2002), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sedano & Burns (2010), Stattersfield & Capper (2000).

97. Yellow-throated Tanager

Iridosornis analis

French: Tangara à bavette jaune **German**: Gelbkehltangare **Spanish**: Tangara Goliamarilla

Taxonomy. *T.[anagra] analis* Tschudi, 1844, Valley of Vitoc, Junín, Peru.
Has been considered to form a superspecies with *I. porphyrocephalus*, and sometimes treated as conspecific; evidence for treatment as two separate species is weak, and sympatry not proven. Monotypic.
Distribution. E slope of E Andes in S Colombia (Serrania de los Churumbelos in E Cauca–W Caquetá, and E Nariño–W Putumayo border), E slope in Ecuador (Sucumbíos S to Zamora-Chinchipe) and almost entire E slope in Peru (S to Puno).



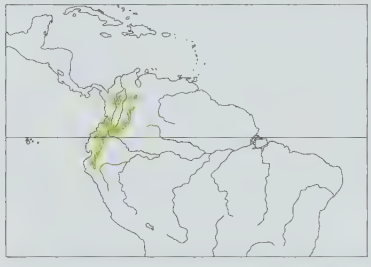
Descriptive notes. 15 cm; 20–29 g. Unmistakable tanager, dark blue above, with yellow throat, and short thick bill. Plumage is mostly dull blue above, darker on crown (especially forecrown) and nape and more greenish-blue on lower back and rump; lores, ocular area and side of head black, forming inconspicuous and weakly defined small mask; upperwing-coverts blackish, edged blue, primary coverts black, flight-feathers and tertials black, edged blue (more broadly on tertials), wingtips black; tail feathers dusky, edged blue; large area on throat rich deep yellow; underparts dull tawny-buff, bluish tinge on chest, sides and flanks; undertail-coverts chestnut; iris reddish-brown; upper mandible black with bluish-grey lower edges, lower mandible bluish-grey; legs dark brownish-grey. Sexes similar. Distinguished from similar *I. porphyrocephalus* mainly by markedly duller appearance, especially below. Immature is like adult, but duller. Voice. Call a thick "euu" and thinner, squeezed "tseeeer", both dropping in pitch. Song a thin, high, somewhat buzzy "ezéétseeu", the notes slurred together, similar to abbreviated song of Sooty Grassquit (*Tiaris fuliginosus*), at intervals of 10 seconds or more; song also reminiscent of that of *I. porphyrocephalus*.
Habitat. Humid and wet montane forest, especially where thick shrubby undergrowth present; regularly along dense forest borders. At c. 1450–2000 m in Colombia (few records) and 1400–2300 m in Ecuador; 1000–2350, rarely to 2600 m, in Peru.
Food and Feeding. Insects and small fruits. Of 13 stomachs examined, three contained only vegetable matter and six only animal matter and four contained both; contents included fruit, seeds, and insects. Seen singly, in loosely associated pairs or in small family parties, which regularly follow mixed-species flocks containing other tanagers; may join feeding aggregations briefly at fruiting trees. Not so active or restless as *Tangara* tanagers; often tends to remain somewhat hidden in vegetation when foraging, although occasionally perches briefly on open branch. Most often observed on mossy limbs or in thick vegetation, where it maintains a rather horizontal body position when foraging. Forages from about eye level to canopy height, more often at middle levels or lower. Hops on lower branches and peers at mossy substrates, where it takes food items.
Breeding. No information.
Movements. Resident. Minor seasonal elevational movements believed to occur in SE Peru.
Status and Conservation. Not globally threatened. Fairly common within middle-elevation montane forest; as yet unrecorded in Bolivia, although likely to be present in that country. Deforestation a cause for concern within parts of this species' range, but it occurs in several protected areas on E slope of Andes, including Cayambe-Coca Ecological Reserve and Sangay and Podocarpus National Parks (Ecuador) and Cordillera de Colán, Tingo Maria and Manu National Parks (Peru). Present also widely in unprotected areas.
Bibliography. Burns (1997a), Burns & Naoki (2004), Burns *et al.* (2002, 2003), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Isler & Isler (1999), Lysinger *et al.* (2005), Mee *et al.* (2002), Meyer de Schauensee (1966, 1970a), Orcés (1944), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schulenberg (2000b), Schulenberg *et al.* (2007), Sedano & Burns (2010), Taczanowski (1884), Terborgh & Weske (1975), Walker (2001), Weske (1972), Zimmer (1944).

98. Golden-collared Tanager

Iridosornis jelskii

French: Tangara à col d'or **German**: Jelskitangare **Spanish**: Tangara de Jelski

Taxonomy. *Iridornis Jelskii* Cabanis, 1873, Maraynioc, Junín, Peru.
Two subspecies recognized.
Subspecies and Distribution.
I. j. jelskii (Cabanis, 1873) – E slope of Peruvian Andes from E La Libertad and San Martín S to Junín.
I. j. bolivianus Berlepsch, 1912 – E slope of Andes from S Peru (Cuzco) S to Bolivia (La Paz).



Descriptive notes. 14 cm; 16–26 g. Distinctive colourful tanager with thick and stubby bill. Nominate race has black face and throat surrounded by broad golden-yellow area that circles rearwards from forecrown and then downwards to side of neck; crown somewhat streaked and flecked with black, nape and hindneck black; upperparts dark blue, becoming slightly paler and duller on rump; lesser and median upperwing-coverts dark blue, greater coverts dusky, edged and tipped turquoise-blue, flight-feathers blackish, narrowly edged bluish; tail blackish, tinged dark blue and edged brighter blue; black of throat bordered by band of dull greenish-chestnut on chest, this becoming rufous-chestnut on breast, belly and undertail-coverts; sides sometimes weakly smudged blue; iris reddish-brown; upper mandible black, lower mandible blue-grey; legs dusky grey. Sexes similar. Juvenile much duller than adult, with rufous wash on belly. Race *bolivianus* slightly smaller, forehead tinged blackish. Voice. Soft high "seep" and "cheep" calls, sometimes two or more in a series, and thin "ti-ti-ti-ti" (of 2–5 notes), similar to those of congeners. Foraging individuals (excited) in mixed-species flock utter sharper, more forceful "tsuk!-eek" and "tsuk!-eek-ee-ee".
Habitat. Humid-forest borders, elfin woodland and dry scrubby hillside vegetation up to tree-line, also dense woody shrubs in *páramo*; sometimes found in bamboo. In most areas at c. 2900 m to 3700 m; regularly (Cuzco) down to 2200 m, occasionally to 2000 m.
Food and Feeding. Of 33 stomachs examined, 24 contained only vegetable matter and four only animal matter and five contained both; contents included berries, seeds, fruit, and insects. Seen alone or in pairs, less often in family groups, individuals perching in fairly upright, alert posture as they forage or move; occurs with mixed-species flocks and also forages independently of them. Forages from below eye level to the tops of small to medium-sized trees. Hops along small branches, and leans down or flutters to take small fruits. Searches for insects along slender, bare or moss-covered branches less than 1·5 cm in diameter. Also takes some prey by gleaning or picking from foliage.
Breeding. Juveniles with adult in Jun and Jul and breeding-condition birds in Nov in Huánuco (Peru). No other information.
Movements. Resident; minor elevational movements may occur in response to changing food resources.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northeast Peruvian Cordilleras EBA and Bolivian and Peruvian Upper Yungas EBA. Uncommon to fairly common. Possibly more numerous than it appears, but inconspicuous, despite bold pattern. Deforestation, especially firewood-cutting of elfin forest and *Polylepis* at or near tree-line, an ongoing problem. No population trends quantified, although likely that the species has declined significantly in areas where habitat damage is severe. Occurs in a few protected areas, e.g. Tingo Maria and Manu National Parks (Peru) and Madidi National Park (Bolivia). Its distributional range includes considerable intact montane woodland and montane scrub that is unprotected, but thought to be at low risk, at least in the near future.
Bibliography. David & Gosselin (2002b), Fjeldså & Krabbe (1990), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Parker & O'Neill (1980), Remsen (1984), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Sedano & Burns (2010), Tallman (1974), Walker (2001), Zimmer (1944).

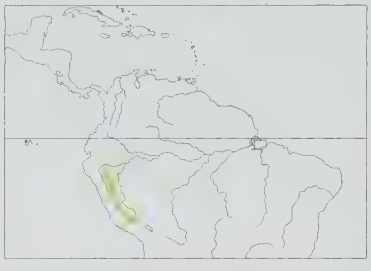
99. Golden-crowned Tanager

Iridosornis rufivertex

French: Tangara auréolé **German**: Goldscheiteltangare **Spanish**: Tangara Coronidorada
Other common names: Blue-bellied Tanager (*caeruleoventris*)

Taxonomy. *Arremon rufi-vertex* Lafresnaye, 1842, Bolivia; error = Bogotá region of east Andes, Colombia.
May form a superspecies with *I. reinhardti*, and sometimes considered conspecific, although there are significant morphological differences. Race *caeruleoventris* may be a separate species; conversely, *ignicapillus* and *subsimilis* differ little from nominate and possibly better synonymized with latter. Four subspecies tentatively recognized.
Subspecies and Distribution.
I. r. caeruleoventris Chapman, 1915 – N end of W Andes (Paramillo) and N part of C Andes (Antioquia S to Tolima), in NW Colombia.
I. r. ignicapillus Chapman, 1915 – SW Colombia (spottily at S end of W & C Andes).
I. r. subsimilis J. T. Zimmer, 1944 – W slope of Andes in Ecuador (S to upper Chiriboga road, in Pichincha).
I. r. rufivertex (Lafresnaye, 1842) – Andes of SW Venezuela (S Táchira), both slopes of adjacent E Andes of Colombia (S to Cundinamarca and on E slope in Nariño), and entire E slope of Andes in Ecuador S to N Peru (near Piura–Cajamarca border and N of Marañón Valley).

Descriptive notes. 15 cm; 18–28 g. Dark but richly coloured tanager with short and thick bill. Nominate race has large circular crown patch of rich golden-orange surrounded by deep velvety black of rest of head, neck and throat; upperparts mainly deep, intense, shining purplish-blue; tail blackish, outer feathers edged dark blue; lesser upperwing-coverts deep purplish-blue (like back), median and greater coverts paler blue, flight-feathers black, inner primaries and secondaries broadly edged blue (like greater coverts), tertials black, outer half of feathers edged blue; black of throat bordered below by shining dark purplish-blue on chest, breast, belly, sides and flanks; centre of belly and undertail-coverts chestnut; iris dark reddish-brown; bill black above, pale greyish below; legs black. Sexes similar. Juvenile is dusky, has wing and tail as on adult but duller, and crown patch duller and smaller. Race *subsimilis* is very like nominate, but coronal patch paler and duller orange-yellow; *caeruleoventris* differs in having crown patch brighter orange-yellow, and vent and undertail-coverts purplish-blue; *ignicapillus* is similar to previous, but undertail-coverts chestnut (as on nominate). Voice. A notably quiet species. Calls include high, thin "seeep", also short "tsit" notes.
Habitat. Dense montane forest, mossy elfin woodland and patches of stunted mossy shrubbery at or slightly above normal tree-line. At c. 2600 m to 3400 m (occasional records down to 2300 m and up to 3800 m) in Colombia; mainly 2500–3300 m (locally 2100–3550 m) in Ecuador; mostly 2900–3700 m (locally down to 2500 m) in Peru.
Food and Feeding. Of three stomachs examined, one contained only vegetable matter and one only animal matter, and one contained both; contents included seeds and insects. Found generally in pairs or in small groups of up to about four individuals, most often associated with mixed-species flocks. Forages usually c. 0·5–5 m up; tends to remain out of sight as it hops and peers in dense foliage, pops out into open briefly, or flies low across small gaps and dives quickly into cover.
Breeding. In Colombia, juveniles in May in Cundinamarca and Cauca, begging juvenile in Jul in Puracé National Park, and juvenile with adult in May in Nariño, and 12 breeding-condition birds in Feb–Aug in C & N end of E Andes; in Ecuador, juveniles in Mar and Jul in NW and juvenile with adult in Aug in N; in Peru, juveniles in Jun in N Cajamarca, Sept in La Libertad and Oct in Amazonas. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common throughout range. As with most upper-montane and tree-line species, firewood-cutting, land clearance and human settlement have reduced and fragmented populations to varying degrees; this species appears not, however, to be facing immediate threats. Occurs in a number of protected areas, including Paramillo, Farallones de Cali and Puracé National Parks (Colombia), Uangantes, Sangay, Cajas and Podocarpus National Parks (Ecuador) and Cordillera de Colán Reserved Zone (Peru).



Bibliography. Bangs & Penard (1919), Best *et al.* (1993), David & Gosselin (2002b), Donegan & Dávalos (1999), Dunning (1982), Fjeldså & Krabbe (1990), Goodfellow (1901), Hilty & Brown (1983, 1986), Isler & Isler (1999), Krabbe *et al.* (2001), Lloyd (2009), Mazar Barnett *et al.* (2006), Meyer de Schauensee (1966, 1970a), Moynihan (1979), Olivares (1969), Parker *et al.* (1985), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Sedano & Burns (2010), Sibley & Monroe (1990), Zimmer (1944).

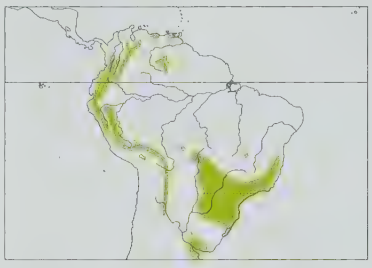
100. **Yellow-scarfed Tanager**

Iridosornis reinhardti

French: Tangara de Reinhardt **German**: Goldbandtangare **Spanish**: Tangara de Reinhardt

Taxonomy. *Iridornis reinhardti* P. L. Sclater, 1865, no locality = east slope of Peruvian Cordilleras.
May form a superspecies with *I. rufivertex*, and sometimes considered conspecific, although there are significant morphological differences. Monotypic.
Distribution. E slope of Andes S of Marañón Valley (from Amazonas to Ayacucho) and Cordillera Vilcabamba (in Cuzco), in Peru.

Descriptive notes. 14 cm; 19·5–28 g. Distinctive dark tanager with yellow band over head; bill stubby and thick. Has head, neck, mantle and throat black, broad golden band extending across hindcrown and downwards on each side of head to ear-coverts (resembling earmuffs or scarf across rear of head); back, rump, uppertail-coverts and breast and lower underparts, including undertail-coverts, intense purplish-blue, occasionally a small amount of chestnut in undertail-coverts; upperwing-coverts, flight-feathers and tertials black, broadly edged greenish-blue (edging not in strong contrast to rest of plumage), tail dark blue; iris dark reddish brown; upper mandible blackish, lower mandible pale grey with black tip; legs blackish. Sexes similar. Juvenile apparently undescribed. Voice. Call a sharp, high-pitched "tzit"; also "tzizi" and "tip" and "ti". A possible song described as a clear (high-pitched) "tsee tsee-dee".
Habitat. Humid montane forest and forest borders, elfin woodland at tree-line, and scrubby low vegetation on hillsides. At 2050–3500 m; most records at 2600–3050 m.
Food and Feeding. Mostly berries and small fruits, supplemented by a few insects. Of ten stomachs examined, six contained only vegetable matter and one only animal matter, and three held both; contents included fruit, seeds and insects. Found in pairs or, more often, parties of 3–5 individuals, and about equally with mixed-species flocks and away from them. Forages from near ground to tops of smaller trees, and occasionally hops on ground; in general inconspicuous, keeps mostly within cover or appears only briefly before retreating again. Obtains food items by hopping quickly through interior of trees, especially on mossy branches, where it probes and picks at moss, including hanging tufts of moss, and sometimes drops down to ground to inspect moss-covered surfaces of roots, rocks, etc. May hang downwards to glean prey from small leaves or bare branches; has been seen moving upwards or downwards in trees rapidly, in a series of short rapid hops.
Breeding. Juvenile with adult in Jun in Huánuco. No other information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Northeast Peruvian Cordilleras EBA and Bolivian and Peruvian Upper Yungas EBA. Fairly common within narrow band of high-elevation forest which its inhabits. Forest destruction, firewood-cutting and other human activities affect the species locally, but long-term populations trends unknown. Occurs in several protected areas, including Cordillera Azul and Tingo Maria National Parks.
Bibliography. Clements & Shany (2001), Fjeldså & Krabbe (1990), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Parker & O'Neill (1980), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sibley & Monroe (1990), Terborgh (1971), Vuilleumier (1970), Walker (2001), Weske (1972).



Genus *PIPRAEIDEA* Swainson, 1827

101. **Fawn-breasted Tanager**

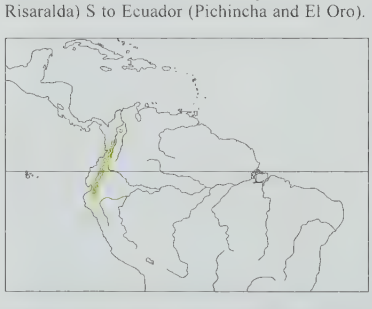
Pipraeidea melanonota

French: Tangara à dos noir **German**: Schwarzrückentangare **Spanish**: Tangara de Antifaz

Taxonomy. *Tanagra melanonota* Vieillot, 1819, Rio de Janeiro, Brazil.
Systematic position of present species has been much debated; recent DNA evidence suggests that it is properly placed in present family and is closely related, and probably sister, to *Thraupis bonariensis*. Taxonomic status of SE populations may be worthy of investigation. Two subspecies recognized.
Subspecies and Distribution.
P. m. venezuelensis (P. L. Sclater, 1857) – mountains of N, NE, SW & S Venezuela (coastal range from Carabobo E to Distrito Federal and Miranda; Sucre and Monagas; locally in Andes from NW & S Lara S to Táchira; Cerro Yaví and Cerro Taracuniña, in N & S Amazonas; probably also mountains of SE Bolívar), and W, C & E Andes of Colombia S on both slopes to Ecuador, Peru (S on W slope to Lima, on E slope throughout), Bolivia and NW Argentina (S to Tucumán and Catamarca).
P. m. melanonota (Vieillot, 1819) – S & SE Brazil (locally SW Mato Grosso; and S Bahia and E Minas Gerais S to C Rio Grande do Sul), E Paraguay, NE Argentina (Misiones and N Corrientes; NE Buenos Aires S to Punta Indio) and S Uruguay.
Descriptive notes. 14 cm; 18–25 g. Unusual tanager with short, wide, hirundinid-like bill with small hook, rather short legs, long wings and short tail, and sky-blue crown. Male nominate race has crown and nape medium blue, forehead, lores, ocular area and ear-coverts deep black, forming broad mask; mantle and back dull blue, lower back and rump contrasting turquoise-blue, uppertail-coverts dark blue, tail dusky blue; upperwing-coverts blackish, rather obscurely edged dark blue, primary coverts and flight-feathers dusky, narrowly edged blue, tertials blackish, more broadly edged dull dark blue; throat and entire underparts buffy cinnamon, variable, from dark buff-cinnamon to buff and to whitish-buff; iris dark red to reddish-brown; bill dusky, with lower mandible usually grey; legs slaty. Female is similar to male, but considerably duller, especially crown, which varies from dull turquoise to dull dusky blue; back tinged brownish, rump dull turquoise (duller than male), uppertail-coverts and tail dull dusky blue, wings duller; underparts generally paler than on male, but amount of buff to buffy whitish likewise variable. Juvenile is dingy brownish-grey above and almost without pattern; immature like female, but duller. Race *venezuelensis* is similar to nominate, but slightly darker above, paler below, and with iris brighter red. Voice. Infrequently heard song a series of high "see" or "sweee" notes, varying from 4 or 5 notes given slowly to a dozen or more uttered very fast like pulsating trill; does not sing regularly, but an individual may occasionally sing over and over for several minutes. In Brazil, a second song type described, more varied and possibly with mimicry.

Habitat. Bushy pastures, cultivated and small semi-open areas with large trees, along forest borders and in clearings with scattered trees; mostly humid areas. Essentially a bird of forest edge and lighter woodland over most of its range. Elevational range varies geographically; in Andes mostly c. 1500–2500 m, occasionally to 3000 m, but as low as 400 m in N Venezuela, and in Colombia down to 900 m on Pacific slope and irregularly up to 2600 m on Sabana de Bogotá; in Ecuador mostly 1000–2800 m, but as low as 400 m on W slope in NW Azuay, and once to 3100 m; in Peru down to 700 m on Pacific slope S to Lima, mainly 1100–2900 m on E slope (a few S Peru records as low as 600 m may represent austral migrants or wandering young); in Bolivia 350–3250 m; in Argentina occurs to 500 m in Tucumán. Nominate race found from sea-level to 2050 m (on Mt Itatiaia) in SE Brazil.
Food and Feeding. Of ten stomachs examined, six contained only vegetable matter and four contained vegetable and animal matter; contents included berries, fruit pulp, seeds, and larvae. Observed also to take moths and ithominid butterflies (Lepidoptera), buds and flowers. Something of a "loner", although sometimes associates with mixed-species flocks, and may appear at fruiting trees with other species. Behaviour may recall that of both *Tersina* and *Tangara*. Seems curiously detached, flighty at times; apt to fly off some distance, flight swift and fluid, before alighting. Forages mostly in canopy or upper levels of trees when in woodlands, but at almost all levels in more open areas, especially when feeding at fruiting trees and shrubs. Often hops along large limbs and perch-gleans; occasionally sallies up and hovers briefly beneath a leaf, or sallies to air for flying insects. Has been seen to search bromeliads and undersides of branches.
Breeding. Fledgling in Jul in W Venezuela (Mérida); nest-building in Mar (Huila) and birds in breeding condition in Mar (Huila) and Jul (Valle) in Colombia; adult carrying nest material in early Mar in SW Ecuador (Tambo Negro, in Loja); and juvenile or immature in Aug in C Peru (Junín). Pair in Peru observed when carrying moss to nest-site 15 m up in clump of epiphytes on tree branch at edge of clearing; nest in Brazil was 20 m up in ferns and epiphytes on horizontal branch. No other information.
Movements. Nomadic or seasonal migratory movements known, but poorly documented. In N Venezuela (coastal cordillera) present mainly Jan–Jun (presumed breeding period); in Pacific Colombia, present Nov–Mar in Anchicayá Valley at 1050 m. Populations in S of range (Argentina) may undertake some seasonal movements N during coolest months.
Status and Conservation. Not globally threatened. Rare to fairly common (periodically or seasonally), and widespread. Occurs in wide range of forest-border and semi-open habitats, and may be expanding its range locally with partial opening of forest in Andes, and perhaps elsewhere. No short-term risks known. Occurs in numerous protected areas over its vast range, which encompasses large amounts of suitable unprotected habitat.

(2000), Belton (1985), Best *et al.* (1996), Brown & Neto (1976), Burns & Naoki (2004), Burns *et al.* (2002, 2003), Collins & Watson (1983), Contreras & Contreras (1993), Donegan & Dávalos (1999), Dunning (1982), Fjeldså & Krabbe (1990), Goodfellow (1901), Hilty (1977, 1997, 1994, 2003), Hilty & Brown (1986), Isler & Isler (1999), Koepcke (1970), Krabbe *et al.* (2001), Meyer de Schauensee (1966, 1970a), Miller (1963), Mitchell (1957), Moore *et al.* (1999), Narosky & Di Giacomo (1993), Olivares (1969), Parker & Goerck (1997), Remsen *et al.* (1987), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sick (1985, 1993), Sick & Pabst (1968), Souza (2002), Taczanowski (1884), Walker (2001), Weske (1972), Zimmer (1943a).



Genus *CHLOROCHRYSA* Bonaparte, 1851

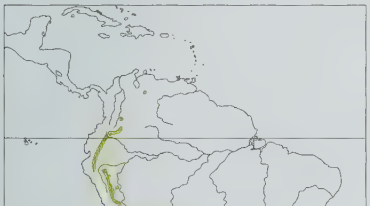
102. **Glistening-green Tanager**

Chlorochrysa phoenicotis

French: Calliste étincelant **German**: Rotohr-Bunttangare **Spanish**: Tangara Verde

Taxonomy. *Calliste phoenicotis* Bonaparte, 1851, Nanegal, Ecuador.
Although genus traditionally placed next to *Tangara* in linear taxonomic sequences, genetic data, together with glistening plumage, leg morphology, and voice, indicate that the two genera are not closely related. Monotypic.
Distribution. Colombia on W slope of C Andes (Antioquia) and Pacific slope of W Andes (from Risaralda) S to Ecuador (Pichincha and El Oro).

Descriptive notes. 13 cm; 20–24·5 g. Small, brilliant green, strong-legged tanager with bill thinner and longer than that of *Tangara*. Male is glistening emerald-green above and below (black feather bases concealed), slightly darker green on back, paler on rump; small inconspicuous tuft of shining greyish-olive feathers behind eye, immediately behind this another small (more conspicuous) tuft of bright orange feathers thickened and club-like at tips; tail blackish, central feathers greenish with bright green edges, outer rectrices edged bright green; lesser and median upperwing-coverts glistening greyish-olive (usually concealed), greater coverts black (mainly inner webs), outer webs broadly edged and tipped bright green; flight-feathers blackish, basal half of outermost primaries very narrowly edged bright green, inner primaries and all secondaries much more broadly edged bright green, tertials mostly bright green, outer half



of inner web blackish; iris dark brown; bill black; legs blackish-grey. Female is similar to male, but slightly duller (although still highly glistening). Juvenile apparently undescribed. Voice. All vocalizations have wheezy or lispy sound. Commonest call during foraging a high, lisping and weak 3-note to 4-note "czee, czee, czee" or more buzzy "ee-see-seez-seez". Song in Ecuador a similar series of notes, more prolonged, "czee-czee-czeet czeet, czee czee czee", last notes slower, this series sometimes followed by extremely rapid series of ticking notes that may accelerate, then slow or end in rapid high-pitched jumble of notes.
Habitat. Canopy and borders of wet mossy forest (cloudforest) and older second growth. Recorded at c. 700–2200 m in Colombia (most records above 1000 m); in Ecuador mostly 600–1700 m, occasionally to 2000 m.
Food and Feeding. Small arthropods, including larvae; also fruit. In Colombian study, insect captures accounted for 62% of foraging records and included many caterpillars, and fruit comprised remaining 38% of records; Melastomataceae berries (especially *Miconia*) accounted for 91% of all fruit eaten. Berries usually swallowed whole. Single individuals, pairs and family groups usually forage with mixed-species flocks containing other tanagers, and regularly visit fruiting trees. In Colombia foraged from higher part of understorey upwards to canopy of small to large trees; median foraging height (63 observations) was 9 m. Notably active and acrobatic, often hangs upside-down from twigs or leaves, or stretches upwards to reach undersides of overhead leaves; also hops or runs rapidly over mossy branches and on epiphytes, and gleans from clumps of moss, bromeliads, vine tangles, hanging dead leaves and, especially, outer foliage. Often searches for insects by hopping rapidly up through palm frond leaflets. Takes small arthropods and larvae especially from undersides of leaves; unlike many species of *Tangara*, does not forage by peering with head downwards.
Breeding. Season evidently May–Sept in Colombia, including two breeding-condition birds in Jun at N end of C Andes, nesting evidence Apr–Jun in Valle, and begging juvenile on 6th Sept in Nariño. One nest in Colombia was a small cup hollowed in moss at medium height on side of limb. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Uncommon. Confined to narrow band of pre-montane and montane wet forest on W slope of Andes in Colombia and Ecuador, an area under intense pressure from deforestation, mining, legal and illegal farming operations, and an expanding human population. Occurs in a few protected areas, most notably Tatamá, Farallones de Cali and Munchique National Parks and Tambito and El Pangan Nature Reserves (Colombia), and probably Maquipucuna Reserve (W Ecuador). Near-term risks to the species are probably low, but the longer-term outlook is less certain.
Bibliography. Burns & Naoki (2004), Chapman (1926), Donegan & Dávalos (1999), Dunning (1982), Fjeldså & Krabbe (1990), Isler & Isler (1999), Hilty (1997, 2009a), Hilty & Brown (1986), Innes (1979), Meyer de Schauensee (1964, 1966, 1970a), Moore *et al.* (1999), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sedano & Burns (2010).

103. Orange-eared Tanager

Chlorochrysa calliparaea

French: Calliste oreillard **German**: Braunohr-Bunttangare **Spanish**: Tangara Orejinaranja

Taxonomy. *C.*[*allospiza*] *calliparaea* Tschudi, 1844, "Chinchon forests", Junín, Peru.
Although genus traditionally placed next to *Tangara* in linear taxonomic sequences, genetic data, together with glistening plumage, leg morphology, and voice, indicate that the two genera are not closely related. Sight records of this species in W Venezuela may refer to race *bourcieri* or to an undescribed race. Three subspecies recognized.
Subspecies and Distribution.
C. c. bourcieri (Bonaparte, 1851) – S Colombia (W slope of E Andes in Cundinamarca S to head of Magdalena Valley, in Huila; E slope of E Andes S from Caquetá) S to E Ecuador and E slope in N Peru (Huánuco S to Huallaga Valley).
C. c. calliparaea (Tschudi, 1844) – E slope of Andes of Peru (Pasco S to N Ayacucho).
C. c. fulgentissima Chapman, 1901 – E slope of Andes of S Peru (from Cuzco) S to Bolivia (S to NW Cochabamba).
Also recorded (race uncertain) on E slope of Andes in W Venezuela (on Mérida–Barinas border).

Descriptive notes. 12 cm; 14·9–21·5 g. Small, strong-legged green tanager with dark throat and narrow orange rump; bill longer and thinner than that of *Tangara*. Male nominate race has body plumage mainly glistening emerald-green, feathers with black bases; small golden-orange patch on centre of crown, prominent bright orange band across lower rump; three central pairs of tail feathers dark green, sharply edged bright green, rest mainly black, narrowly edged bright green; upperwing-coverts black, edged bright green, outer half of feathers tinged green; primary coverts black, flight-feathers black, basal half of outermost primaries edged bright green, rest of primaries and all secondaries almost entirely edged bright green, tertials edged bright green and outer web of each feather greenish, inner web blackish; throat black, joining with conspicuous, triangular-shaped, small burnt-orange patch on side of neck, otherwise glistening green below, lower breast and belly intense glistening dark blue-green; iris dark brown; bill black; legs dark grey. Female is like male, but somewhat duller green, with less bluish on belly, smaller neck patch. Immature is mainly dull green. Race *bourcieri* is similar to nominate, but blue of lower underparts less dark and less intense, female much duller, with grey throat, smaller orange neck patch, only hint of blue on belly; *fulgentissima* has crown patch yellowish, neck patch bright red, and throat and entire central area of breast and belly deep violet-blue, female extensively violet-blue on throat and breast, like male but duller, retains red neck patch. Voice. Dawn song a slow series of 4–8 or so notes, "pseet pseet pseet pseet pseet", rather high-pitched, wheezy and lisping. Song, in Peru, described as a complex, long series of high, wiry warbles, with certain phrases repeated many times. Call a high, wheezy "seeep".
Habitat. Favours humid and wet middle-elevation mossy forest (cloudforest), forest borders, and taller second growth. At 900–2000 m, but most records c. 1000–1700 m; 1600–1800 m in upper Magdalena Valley, in Colombia. Reported in Venezuela at c. 1450 m.
Food and Feeding. Small arthropods; also fruit, especially small berries, such as those of *Miconia* and other melastomes. Of nine stomachs examined, seven contained only vegetable matter, one only animal matter and one both; contents included fruit, seeds, and six caterpillars (five larger than 20 mm). Usually found singly or in pairs, and usually foraging with mixed-species flocks containing other tanagers, especially *Tangara*. Forages mostly between middle heights and canopy. Moves in speedy fashion, running out along mossy branches and into terminal foliage, often hanging upside-down from twigs, petioles and leaves; spending more time searching for small arthropod prey than seeking fruit.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon in N of range, locally more numerous towards S. Inhabits narrow band of wet E slope pre-montane and montane forest that is under pressure in many areas from human settlement and deforestation. Occurs in some protected areas, among them Cordillera Los Picachos National Park (Colombia), Cayambe-Coca Ecological Reserve and Sangay and Podocarpus National Parks (Ecuador), Manu National Park (Peru) and Madidi National Park (Bolivia). Within its range there also is extensive intact habitat that is unprotected, but secure in at the short term.
Bibliography. Burns (1997a), Burns & Naoki (2004), Burns *et al.* (2002, 2003), Goodfellow (1901), Hilty (1999, 2003), Hilty & Brown (1986), Isler & Isler (1999), Lysinger *et al.* (2005), Mee *et al.* (2002), Meyer de Schauensee (1964, 1966, 1970a), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010), Terborgh & Weske (1975), Walker (2001), Zimmer (1930, 1943a).

104. Multicolored Tanager

Chlorochrysa nitidissima

French: Calliste multicolore **German**: Schwarzohr-Bunttangare **Spanish**: Tangara Multicolor

Taxonomy. *Chlorochrysa nitidissima* P. L. Sclater, 1874, Antioquia, Colombia.
Although genus traditionally placed next to *Tangara* in linear taxonomic sequences, genetic data, together with glistening plumage, leg morphology, and voice, indicate that the two genera are not closely related. Monotypic.
Distribution. Colombia: locally on both slopes of W Andes from Risaralda and extreme S Antioquia S to W Cauca (Munchique area); and C Andes at N end (Antioquia), on W slope (Quindío, and reported from Ucumarí Regional Park, in Risaralda) and on E slope (Caldas).

Descriptive notes. 12 cm; 17·3–21·6 g. Small, strong-legged tanager with mostly yellow head and glistening harlequin-patterned plumage; bill longer and thinner than that of *Tangara*. Male has forehead to mid-crown, side of head to behind eye, and throat bright golden-yellow, centre of throat golden-orange, oval black patch on ear-coverts bordered behind and below by chestnut; rear crown and nape glistening golden-green; large, triangular glistening lemon-yellow patch on mantle and upper back, lower back to uppertail-coverts glistening turquoise-blue; tail dusky, central feathers tinged green and edged bright green, outer feathers mainly edged bright green; upperwing-coverts dusky, prominently edged and tipped bright green; flight-feathers dusky, basal half of outermost primaries and entire length of rest of primaries edged bright green, secondaries and tertials with outer half of each feather green and also edged brighter green; breast and lower underparts mostly glistening turquoise-blue, sides and flanks mixed glistening green and blue, centre of lower breast and belly black, undertail-coverts glistening blue-green; iris dark brown; bill black; legs dark grey. Female is similar to male, but considerably duller, head mostly dull yellow with blackish-chestnut ear patch, golden-yellow of throat somewhat stained brownish along sides, entire mantle and back bright greenish (no yellow patch on mantle), rump glistening bluish-green, tail and wings as on male but slightly duller green; glistening green below, somewhat duller on lower underparts. Immature is like female, but even duller. Voice. Call one to several wheezy "ceeet" or "swee" notes, similar to those of *C. calliparaea*. Possible song may consist of a brisk series of c. 4 wheezy "swee-see-see-see" notes.
Habitat. Humid and wet mossy forest, tall older second-growth woodland and forested borders, at c. 1300–2200 m in C Andes and E slope of W Andes; very locally on Pacific slope down to 900 m.
Food and Feeding. Few data. Reported food items include insects, mainly taken when foraging with mixed-species flocks in forest interior. Also fruit.
Breeding. Stub-tailed juvenile with two adults on 1st Nov and grown juvenile on 8th Jan in W Andes above Cali (Valle del Cauca). No other information.
Movements. Evidently resident.
Status and Conservation. VULNERABLE. Restricted-range species: present in Colombian Inter-Andean Slopes EBA and Chocó EBA. Uncommon, local and declining. Since 1951 recorded at only two sites in C Andes, Ucumarí Regional Park (Risaralda) in early 1990s and, farther N, near Anorí (Antioquia) in 1999; in W Andes, almost all modern records are from localities in Valle del Cauca where access by ornithologists is possible. This species was formerly common, but has declined throughout range and is now recorded only infrequently and very locally, primarily in remnant forest fragments. Perhaps greatest number of recent sightings in W Andes in vicinity of Cali and N of there, including Pichindé Valley (unprotected), private forests near El 18 (Bosque de San Antonio, above Cali), Yotoco Forest Reserve, Tambito Nature Reserve and Farallones de Cali, as well as to S in Munchique National Park; also in C Andes at Otún-Quimbaya Sanctuary, in Ucumari section of Los Nevados National Park (Risaralda), and in Reserva Arrierito Antioquena (Piha Reserve) and adjacent Anorí area (N Antioquia). Other sites include Cañon del Río Barbas y Bremen (Risaralda), La Finca la Betulia–Reserva la Patasola (Quindío), La Forzosa–Santa-Gertrudis, and La Victoria. A few large tracts of intact habitat remain within its range (Farallones de Cali and Los Nevados National Parks; and Caramanta massif, near Cerro Tatamá, including Alto de Pisones area), but deforestation has been severe and continues. Furthermore, within its range an expanding network of roads is opening up ever more remote areas to logging, mining, agriculture and human occupation, all of which lead to more deforestation. This species' range is now highly fragmented, and populations are in critical need of baseline monitoring data.

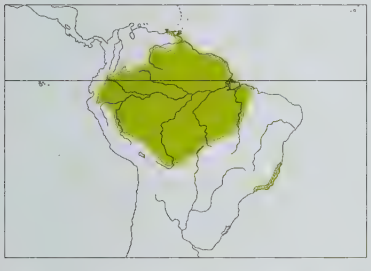
PLATE 11

inches 3
cm 8



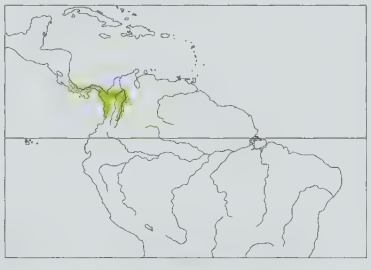
Genus *TANGARA* Brisson, 1760

105. Turquoise Tanager

Tangara mexicana

French: Calliste diable-enrhumé **German**: Türkistangare **Spanish**: Tangara Turquesa
Other common names: White-bellied Tanager (*brasiliensis*)

Taxonomy. *Tanagra mexicana* Linnaeus, 1766, Cayenne, French Guiana.
Based on genetic data this species is sister to *T. inornata*. Race *brasiliensis*, long regarded as a separate species because of its larger size, paler plumage and geographical isolation, has more recently been treated as a race of present species, but status merits further consideration. Proposed race *lateralis* (described from Apacy, on R Tapajós) is now generally considered an intergrade between nominate and *boliviana*; further study required. Five subspecies currently recognized.
Subspecies and Distribution.
T. m. vieilloti (P. L. Sclater, 1857) – Trinidad.
T. m. media (Berlepsch & E. J. O. Hartert, 1902) – E Colombia (Vichada) and NE & S Venezuela (Monagas, Sucre Delta Amacuro and, S of R Orinoco, Amazonas and Bolívar).
T. m. mexicana (Linnaeus, 1766) – the Guianas and Brazil (E to E Pará and S to C Mato Grosso).
T. m. boliviana (Bonaparte, 1851) – E Colombia (from W Meta and R Guaviare) E through Amazonian Brazil to Pará, W Goiás and C Mato Grosso, S through E Ecuador and E Peru to N & NE Bolivia (Santa Cruz).
T. m. brasiliensis (Linnaeus, 1766) – coastal SE Brazil (S Bahia S to Rio de Janeiro).



Descriptive notes. 14 cm, 26 g (*brasiliensis*); 12 cm, 17–23·5 g (other races). Small tanager with dark, mottled appearance and contrasting yellow belly. Nominate race has mid-crown to nape and most of upperparts deep velvety black, glistening pale blue rump and uppertail-coverts somewhat mottled with black; tail black, all feathers except central pair edged dark blue; small black area encircling bill, narrow black orbital ring, faint blue supercilium, otherwise forecrown, side of head and throat to upper breast glistening cobalt-blue to purplish-blue, some black feather bases showing as mottling and spangling (especially on lower throat, and continuing to side of neck and to central breast); lesser upperwing-coverts turquoise-blue, median coverts black, broadly tipped shining blue, greater coverts black, narrowly edged blue, primary coverts black, edged blue; flight-feathers black, basal half of outer feathers edged pale blue; lower breast, belly and undertail-coverts pale yellow, sides and flanks blue to purplish-blue with heavy black scalloping and spotting; iris dark brown; bill and legs black. Sexes similar. Juvenile is mainly dull dusky blue above and dull pale yellowish-white below, with dusky on chest; immature plumage pattern more like that of adult, but duller above and below. Race *boliviana* differs from nominate in having lower breast to undertail-coverts richer-coloured, bright creamy yellow; *media* differs in more well-defined blue eyebrow (but still inconspicuous), sides and flanks heavily spotted, and with little violet-blue; *vieilloti* has blue of head and breast darker than previous, and yellow lower underparts richer and brighter; *brasiliensis* is significantly larger, overall paler, more silvery blue, including lesser wing-coverts, and with white (not yellow) lower underparts. Voice. Calls mainly rapid streams of high, chipping "tic" notes, often accelerating into trills, especially as group takes flight; higher-pitched than calls of many congeners. No song yet described.
Habitat. Humid forest borders, broken second growth, lighter or disturbed forest, trees in clearings, along river and oxbow-lake edges, and along gallery forests in partly open areas; small numbers also in upper canopy and emergent treetops of lowland forest. Lowlands to c. 500 m over most of range; to 1000 m in Colombia and Venezuela (once to 2000 m on Cerro de la Neblina, in S Venezuela); isolated race *brasiliensis* to 500 m in SE Brazil.
Food and Feeding. Arthropods and fruits. Of four stomachs examined, three contained only vegetable matter and one only animal matter; additional contents included mistletoe berries (Loranthaceae). In Trinidad, recorded as eating 26 species of fruit, of which 31% were berries of *Miconia* species; other fruit prominent in diet included *Cecropia* (13%), *Ficus* (10%) and *Ilex* (8%); in SE Brazil (race *brasiliensis*), recorded as taking buds of Leguminosae, melastome berries, pieces of guava fruit (*Psidium*), and bananas. Notably social, lives in groups of 3–10 individuals, sometimes more; usually independent of mixed-species flocks, or associates with them irregularly or for only short periods of time. In SE Brazil, more often seen in pairs. Forages from canopy down to about eye level, higher when searching for insects. In Trinidad, insect-seeking accounted for 47% of 433 foraging records, fruit for 53%; typically, took berries while perched and either swallowed them whole or mashed them; pecked pieces from larger fruit. Most insects sought on underside of rather open bare and often dead branches of c. 1·3 cm or less in diameter (91% of 201 insect-hunting records); also spent some time in searching foliage, flowerheads and seedheads, and made sallies to air. Elsewhere in range, foraging behaviour similar to that observed in Trinidad, this species favouring middle levels to high open, bare branches as foraging sites.
Breeding. In E Colombia nests reported in Feb and Oct; season Apr–Oct in Trinidad and Feb–Apr and Aug in Suriname; recorded Nov in Pará, in Brazil. Pairs separate from flock to breed, but start rejoining flock intermittently as soon as eggs hatch. Co-operative breeding recorded at two nests in Trinidad, where nestlings fed by and attended by all members of group from hatching until independence. Nest built by female, attended by male, a deep cup of moss and fibres, decorated on outside with lichens and leaves, two Trinidad nests 6 m and 7·5 m above ground, one in upright fork of mango tree; reported as usually nesting high in Suriname; a Brazil nest was in branch fork in shrub. Clutch 2–3 eggs, greyish to greenish with brown or purple markings; in captivity, incubation period 12–14 days. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Widespread, and uncommon to locally common; small isolated population along coastal SE Brazil (*brasiliensis*). Found in many protected areas and also widely in unprotected areas. Primarily an "edge" species that derives some benefit from limited forest disturbance. Status of *brasiliensis* more problematic, because of extreme deforestation in coastal region of SE Brazil; may be largely confined to protected areas, such as Sooretama and Poço das Antas Biological Reserves, among others.

106. Plain-colored Tanager

Tangara inornata

French: Calliste gris **German**: Schlichttangare **Spanish**: Tangara Cenicienta
Other common names: Plain Tanager

Taxonomy. *Calliste inornata* Gould, 1855, Santa Fé de Bogotá, Colombia.
Based on genetic data this species is sister to *T. mexicana*. Three subspecies recognized.
Subspecies and Distribution.
T. i. rava Wetmore, 1963 – Caribbean slope in Costa Rica (S from Heredia) and Panama (S to Colón and Coclé).
T. i. languens Bangs & Barbour, 1922 – Panama (Caribbean side E from Colón and Coclé, and Pacific slope E from W Panamá) E to Colombia (Chocó, and S in Pacific lowlands to N Valle del Cauca).
T. i. inornata (Gould, 1855) – N Colombia at N base of W Andes (Sinú Valley in Antioquia), lower Cauca Valley (in Antioquia), and middle Magdalena Valley (from Antioquia S to Caldas, Santander, Boyacá and Cundinamarca).

Descriptive notes. 12 cm; 16·4–19·1 g. One of the few members of genus that lacks colourful plumage. Nominate race is mainly dark lead-grey on head and back, slightly paler grey on rump and uppertail-coverts; lesser upperwing-coverts bright blue (usually concealed), rest of coverts, flight-feathers and tail plain blackish; throat, chest and sides plain neutral-grey, fading to dull whitish (or faintly tinged buff-white) on centre of breast, belly and undertail-coverts; underwing-coverts white; iris dark brown; bill and legs black. Sexes similar. Immature is duller and even plainer than adult. Race *rava* is similar to nominate, but has faint buff tinge on breast, more prominent buff on belly and undertail-coverts; *languens* differs in having head and upperparts decidedly paler, more plain grey, rump slightly paler than back, and throat and chest slightly paler grey than nominate, central breast tinged buffy white (not white). Voice. Song of c. 15 notes, a short fast series of "tsst" that gradually slows; also described as a random series of high thin whistles, short staccato notes and sputters, "tseee tsp tsp tsee tsp tseee tseee tsp tsp tsp". Calls mostly high-pitched, sibilant, and not especially distinctive, including "tst", "tsit", "tseep" and "jeet", singly or sometimes accelerating into rapid dry trill; short "trrr" in flight.
Habitat. Humid forest borders, second growth and disturbed or semi-open areas, gardens, parks, plantations and urban areas with trees; occasionally forest canopy. Lowlands to c. 400 m in foothills in Costa Rica; to 800 m in Panama and to 1000 m in Colombia.
Food and Feeding. Arthropods and fruit. In Panama recorded as eating wide variety of small (3–5 mm) fruits, including those of *Tetracera* (Dilleniaceae), *Lantana* (Verbenaceae) and *Hamelia* (Rubiaceae), and catkins of *Cecropia*; last-mentioned commonly consumed throughout range. Lives in pairs or in groups of 3–4 when breeding; in groups of up to about six individuals, occasionally larger groups, outside breeding season. Nervous, fidgety, almost hyperactive, and often noisy as it constantly flicks wings and tail, and flies from tree to tree. Forages mainly in canopy of trees, but descends to shrubs for fruit.
Breeding. All information from Panama. Season Mar–Aug. At one nest two nestlings fed by four adults, which visited together. Nest a tidy cup of light-coloured fibres covered with green moss, spider webs and cocoon silk; each of three nests c. 9 m up in foliage of fruiting tree, another nest 20 m up. Clutch 2 eggs, whitish, speckled. No other information.
Movements. Resident. Reported seasonal variation in numbers in C Panama, suggesting some regional movements.
Status and Conservation. Not globally threatened. Uncommon to fairly common in much of range. Found in several protected areas, including Metropolitan, Soberanía, Chagres and Darién National Parks (Panama) and Los Katíos National Park and El Paujíl Reserve (Colombia). This species' range also includes much suitable second-growth and forest-edge habitat. Unlikely to face any risks in immediate future.
Bibliography. Burns & Naoki (2004), Davis (1972), Dunning (1982), Eisenmann (1952), Garrigues & Dean (2007), Greenberg (1981c), Hilty & Brown (1986), Isler & Isler (1999), Karr (1977), Leck (1971a, 1971b, 1972c, 1975), Meyer de Schauensee (1964, 1966, 1970a), Moynihan (1962c), Olivares (1969), Remsen *et al.* (2010), Ricklefs (1976), Ridgely & Gwynne (1989), Salaman *et al.* (2008), Sedano & Burns (2010), Skutch (1954, 1976), Slud (1964), Stiles (1983), Stiles & Skutch (1989), Strauch (1977), Wetmore *et al.* (1984), Willis (1980), Willis & Eisenmann (1979).

107. Azure-rumped Tanager

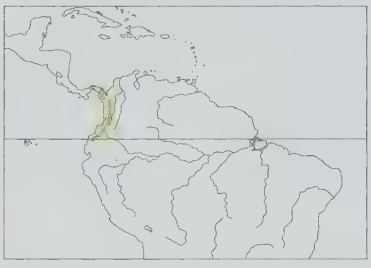
Tangara cabanisi

French: Calliste azuré **German**: Cabanistangare **Spanish**: Tangara Chiapaneca
Other common names: Cabanis's Tanager

Taxonomy. *Calliste cabanisi* P. L. Sclater, 1868, Costa Cuca, Guatemala.

On following pages: 108. Grey-and-gold Tanager (*Tangara palmeri*); 109. Paradise Tanager (*Tangara chilensis*); 110. Seven-colored Tanager (*Tangara fastuosa*); 111. Green-headed Tanager (*Tangara seledon*); 112. Red-necked Tanager (*Tangara cyanocephala*); 113. Brassy-breasted Tanager (*Tangara desmaresti*); 114. Gilt-edged Tanager (*Tangara cyanoventris*).

Originally described under name *Calliste sclateri*, but that name is invalid, as preoccupied. On basis of plumage, habitat and voice appears most closely related to *T. palmeri*. Monotypic.
Distribution. S Mexico (Sierra Madre de Chiapas) and adjacent SW Guatemala.



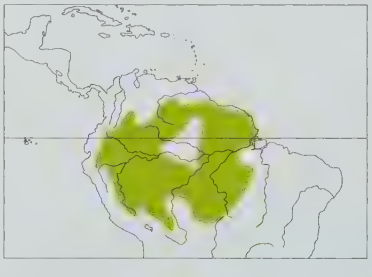
Descriptive notes. 14 cm. Pale blue-grey tanager with black-speckled collar across whitish chest. Has crown bluish-grey, becoming silvery blue on nape, bluish-green on mantle and azure-blue on rump; crown and back somewhat speckled and scaled with dusky; lesser upperwing-coverts mostly pale blue (turquoise-blue), median and greater coverts black, edged bluish, flight-feathers black, all except outermost primaries edged pale blue, tertials black, more broadly edged pale blue; tail feathers blackish, narrowly edged pale blue; lores black, black extending narrowly over bill, and blackish line across lower ear-coverts (variable in extent and length); otherwise, face and entire underparts pale bluish-white to greenish-white (varies with light), lower throat, chest and upper breast somewhat scaled and mottled with black (forming speckled collar); iris dark brown; bill dark grey, dusky tip; legs blackish. Differs from similar *T. palmeri* mainly in smaller size and more bluish appearance. Sexes similar. Juvenile is like adult, but duller, crown greyish with pale blue tinge, back similar but with small amount of dark mottling, lesser wing-coverts greyish, flight-feathers edged duller blue, lores blackish, lower edge of ear-coverts with variable number of dark markings, whitish below, breast with minor dark mottling (amount variable), bill grey; older juvenile soon moults into plumage essentially identical to that of adult. Voice. Calls include high, rising "seee", rapid "chi-di-di-dit", high tittering notes and, in chases in flight, a buzzier "bzzz bzzz bzzz zeeah" and other notes. Song, delivered from high bare treetop branch, apparently a high, thin "seeeeawit, chi-di-di-di", sometimes repeated in rapid succession; may sing for several minutes from one perch, then move to another and continue singing.
Habitat. Tall humid broadleaf evergreen forest, forest borders and small plantation-like clearings with scattered trees, at 600–1800 m; most records above 1000 m, mainly 1250–1650 m.
Food and Feeding. Observed to eat figs (*Ficus*), melastome berries and insects in Mexico. Most often seen singly or in pairs, but noted also in small groups, and once a party of 26 individuals; occasionally forages with mixed-species flocks, but apparently more often independent of them. Active and noisy bouts of foraging interrupted by periods of quiet and rest in tops of large trees. Forages mostly in upper levels and canopy of forest, but sometimes lower, and once on ground at base of melastome shrub. Insect-searching behaviour included peering at leaves and leaf axils, examining undersides of outer branches by hopping and leaning down, first on one side, then on other, to inspect mossy branches; also examined mossy branches less than 5 cm in diameter, and often executed short clumsy or heavy aerial sallies from exposed perches above canopy.
Breeding. Breeding recorded in early wet season, mid-Apr to mid-Jun, in Mexico although wet season extends to Sept. Co-operative breeding with helpers recorded; 4–6 birds in adult plumage observed at nest, although not known if all contributed food. Most of following details from a year-long study in which eight nests were located. Nest material brought by both adults, but more of construction work carried out by one member of pair (presumably female); cup-nest of moss and lichen, placed usually in fork where foliage densest and near end of long horizontal branch in upper half of large tree (taller than 15 m), five of eight nests in *Ficus cookii*; also, one nest reported in pine (*Pinus*), one in exotic *Cupressus*, another in an *Inga* growing over coffee, and one mossy cup-nest was 12 m above ground in branch fork c. 1·5 m from end of large limb of fig tree overhanging canyon. Clutch apparently 2 eggs (inferred from number of nestlings), undescribed; incubation presumably by female alone, at two nests for, respectively, 73·9% and 81·7% of daylight hours, average length of incubation stint 18·7 minutes (average recess 6·7 minutes) at one nest and 20·7 minutes (average recess 5·7 minutes) at other, incubation period c. 14 days; chicks fed by both adults, also by helpers when present, c. 5–8 feeding visits per hour, helpers accounted for 4% of feeds at onset and up to 38% on day before young left nest; nestling period c. 15 days. Data from six nests indicated nest success c. 29–43%.
Movements. Resident. During year-round study believed to remain on territory throughout.
Status and Conservation. ENDANGERED. Restricted-range species: present in North Central American Highlands EBA. Locally common to rare. An extremely localized and declining species. Known from five localities in SE Mexico, but all recent reports from El Triunfo Biosphere Reserve (mainly in buffer zone, which includes numerous expanding settlements). In adjacent Guatemala presently known from eight sites, including S slope of Volcán Santa María, Dos Marías Reserve, San Maracos, Volcán Tajumulco, Volcán Atitlán, and middle valley of R Madre Vieja N of Pochuta. Most of these sites have some legal protection, including as private nature reserves, and include coffee plantations and primary forest. Within these very restricted areas the species appears to be locally common. Expanding human settlement and loss of habitat from deforestation are main threats; some revenue from tourism and birdwatching at these sites, however, is helping local communities to realize a benefit from conserving these areas.
Bibliography. Álvarez del Toro (1964), Anon. (2010a), Blake (1953), Brodkorb (1939), Butchart & Stattersfield (2004), Davis (1972), Eisenmann (1955), Eisermann, Arbeiter, López, Avendaño & de León Lux (2011), Eisermann, Arbeiter, López, Avendaño, de León Lux, Burge *et al.* (2011), Eisermann, López *et al.* (2011), Gómez de Silva *et al.* (1999), Heath & Long (1991), Hilty & Simon (1977), Howell & Webb (1995), Isler & Isler (1999), Land (1970), Long & Heath (1994), de Silva Garza (1997), Stattersfield & Capper (2000).

108. Grey-and-gold Tanager

Tangara palmeri

French: Calliste or-gris **German**: Palmertangare **Spanish**: Tangara Grisdorada

Taxonomy. *Calospiza palmeri* Hellmayr, 1909, River Sipí, Chocó, Colombia.
On basis of plumage, habitat and voice appears most closely related to *T. cabanisi*. Monotypic.
Distribution. E Panama (including Cerro Tacarcuna, Altos de Quía, Cerro Pirre and Cerro Sapo; sight records from Nusagandi, in E San Blas province, and Cerro Azul), and Pacific slope and lowlands of W Colombia and W Ecuador (S to Esmeraldas and Pichincha; also Cordillera de Chindul, in N Manabí).
Descriptive notes. 15 cm; 30–32·6 g. Fairly large, plump, predominantly grey and black *Tangara* with black-speckled foreparts; "gold" colour inconspicuous. Plumage is mostly light pearly grey above (depending on angle of light), the grey of mantle mixed with black speckling and sprinkled with gold and silvery green, scapulars black; short black mask across base of forehead and extending through lores to just behind eye and to chin; lesser upperwing-coverts medium grey, median and greater coverts black, edged and tipped grey, flight-feathers and tertials black, edged grey; tail feathers black, edged grey; throat, side of head and median underparts off-white, variable black



speckling of neck extending down across lower side of chest to form irregular necklace of black speckling, this mixed with gold across pectoral area; sides and flanks tinged medium grey, undertail-coverts white; iris dark brown; bill black; legs dark grey. Sexes similar. Juvenile is much duller and dingier than adult, with bill greyish and no gold on chest; soon moults into plumage that closely resembles that of adult. Voice. Unlike most congeners, a notably vocal species. Several semi-musical calls and staccato notes, most common of which is a sweet "chup chup-sweeeeet", last long note rising and often given over and over, or any of these notes given singly. Pair-members greet and fly off rapidly with energetic series of "chip", "chup", "sweet" and other notes.
Habitat. Mainly humid to very wet (pluvial) forest, often on steep hillsides, forest borders, tall second growth and scattered trees in clearings. Lowlands to c. 1100 m; most numerous above c. 300 m in Colombia and above c. 400 m in Ecuador.
Food and Feeding. Fruits and berries, and arthropods. In W Colombia observed to eat more than 32 species of fruit (80% of 541 observations); *Miconia* berries accounted for 40% of all fruit eaten, *Cecropia* a further 35%, and figs (*Ficus*) 7%. One individual seen to take insects to a nestling. Lives in pairs or in lively, excitable groups of 3–8 individuals, and may forage with mixed-species canopy flocks for short periods, but typically moves too rapidly for other species to follow and apt to fly off long distances before alighting again; reported in about half of mixed-species flocks at one site in upper Anchicayá Valley (W Valle del Cauca), in Colombia. Forages mainly in canopy or upper levels of trees, occasionally down to middle heights, rarely down to 3 m above ground; unlike congeners, does not regularly descend low to fruiting shrubs. Median foraging height in 450 observations of foraging was c. 12 m. Typically, takes berries and small fruits from upright perched position by leaning out to pluck the item, rarely plucks fruit while in flight; often takes *Cecropia* catkins by hanging with head downwards. Small berries swallowed whole; eats large ones piecemeal by pecking and squeezing or mashing pieces before swallowing. Almost all insects captured during aerial sallies (82% of 106 insect-hunting observations). Often perched near flowers that attracted insects, and was observed to sally to foliage for arthropod prey. May hop along treetop branches or explore foliage, but does not employ "leaning-down" search motion of many congeners. One member of a pair was seen to be struck and killed in flight by a Bat Falcon (*Falco rufigularis*) in Colombia.
Breeding. Nests found in early Jul, early Aug and Dec; nest-building seen in Jan, and nest in Feb and pair feeding fledgling in Apr; in upper Anchicayá Valley (W Colombia) some breeding may occur all year. Nest a mossy cup placed c. 30 m above ground on large, moss-covered branch. No other information.
Movements. Resident; no evidence of any seasonal movements in W Colombia.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs at rather low density or distributed locally in Chocó–Pacific forests. Occurs in a few protected sites, such as Los Katíos National Park, possibly also Farallones de Cali National Park and El Pangan Nature Reserve, in Colombia. Species' range includes considerable intact forest that is unprotected, but much of this (at least in Colombia) may ultimately be at risk in the long term. The species persists, in small numbers, in tall old second growth or partly disturbed areas. In Ecuador most numerous in Esmeraldas, but continues to be reported at Tinalandia, a privately held property in Pichincha; current status in Cordillera de Chindul, in Manabí, uncertain. Baseline population-monitoring desirable.
Bibliography. Angehr *et al.* (2004), Dunning (1982), Hilty (1981, 1997, 2009a), Hilty & Brown (1986), Hilty & Simon (1977), Isler & Isler (1999), Jahn *et al.* (2002), Lehmann (1957), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Naoki (2003c), Pearman (1993), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Robbins *et al.* (1985), Salaman *et al.* (2008), Sedano & Burns (2010), Wetmore *et al.* (1984).

109. Paradise Tanager

Tangara chilensis

French: Calliste septicolore **German**: Siebenfarbentangare **Spanish**: Tangara del Paraíso

Taxonomy. *Aglaïa Chilensis* Vigors, 1832, no locality = Bolivia.
Molecular data indicate that this species is most closely related to *T. velia* and *T. callophrys*. Race *caelicolor* intergrades with *paradisea* in E Venezuela and Guyana. Race *caelicolor* often misspelt "*coelicolor*" but former is the original spelling. Four subspecies recognized.
Subspecies and Distribution.
T. c. paradisea (Swainson, 1837) – SE Venezuela, the Guianas and N Brazil (S to N bank of R Amazon).
T. c. caelicolor (P. L. Sclater, 1851) – E Colombia (Meta, Guainía and Vaupés), S Venezuela (Amazonas) and NW Brazil (R Uaupés and upper R Negro).
T. c. chilensis (Vigors, 1832) – S & SE Colombia (W slope of E Andes in upper Magdalena Valley, in Huila; and Caquetá, Putumayo and Amazonas) S to E Ecuador, E Peru and Bolivia (S to Santa Cruz), and E through W Brazil (E to Rondônia, SE Amazonas E Mato Grosso and SE Pará).
T. c. chlorocorys J. T. Zimmer, 1929 – N Peru (upper Huallaga Valley).

Descriptive notes. 12–13 cm; 16–17 g (*paradisea*), 17–27 g (nominate and *chlorocorys*). Unmistakable tanager with a harlequin pattern of contrasting colors. Nominate race has most of crown and side of head scaly apple-green (feathers with black bases and pale green tips), narrow black line over bill and prominent (almost clown-like) black orbital ring; hindcrown, nape and back deep velvety black, lower back and rump entirely bright red or (e.g. Tres Esquinas area of Caquetá, in Colombia) changing to orange narrowly on uppertail-coverts; tail uniformly black; bend of wing and lesser upperwing-coverts turquoise, median coverts cobalt-blue, greater coverts, flight-feathers and tertials deep black, basal half of primaries (except innermost ones), as well as primary coverts, edged cobalt-blue to purplish-blue; throat to central chest glistening violet, breast, sides and flanks glistening turquoise-

blue, centre of belly and undertail-coverts deep black; iris dark brown; bill jet-black; legs dark grey to black. Sexes similar. Immature is similar to adult, but duller, with lower back variously orange to orange-red. Race *caelicolor* is similar to nominate, but lower back and most of rump flame-red and uppertail-coverts contrastingly bright golden-yellow; *paradisea* differs from previous mainly in having red of lower back slightly paler and more restricted in extent, uppertail-coverts lighter yellow, also differs from nominate in smaller size, and median wing-coverts same colour as throat (not paler cobalt to turquoise); *chlorocorys* is similar to *caelicolor*, but larger, green of top of head extending farther rearwards, and green colour is brighter, more yellowish-tinged. Voice. Noisier than most congeners. Individuals, especially when in flock, almost constantly give rapid, high-pitched chipping notes, including sharp "chak", and a rising "zeet" or "swee", either singly or in excited series, sometimes rapidly. Notes given in flight and during foraging or moving rapidly through canopy. Dawn song "cheek, cheet" (second note may be slightly higher-pitched) repeated over and over in long, somewhat irregular series, average c. 13 notes in 10 seconds; also described, in Peru, as a regularly spaced series of "swee? tchip" phrases. Day song in SE Peru "tsip seeea-wee", repeated over and over.

Habitat. Everywhere found in high canopy and treetops, and often in canopy of emergent trees (leafless or with foliage) such as *Ceiba pentandra*. In Amazonian lowlands, occurs in tall humid *várzea* and *terra firme* forest, somewhat less frequently in forest borders or tall second growth, or tall trees in clearings. In humid and wet Andean foothills and at lower elevations, occupies variety of forested habitats, including broken landslide and steep hillside forest, occasionally even rather scrubby woodland. Lowlands to c. 1500 m or slightly higher.

Food and Feeding. Fruits and small berries, also arthropods; observed to eat *Miconia* berries and fruits of *Aralia*. Of twelve stomachs examined, ten contained only vegetable matter and one only animal matter and one contained both; contents included fruit pulp and insects. Other stomachs contained seeds, fly larvae (Diptera), short-horned grasshoppers (Caelifera) and spiders (Araneae). At one nest chicks fed with spiders, orthopterans and caterpillars. Excitable and noisy, and notably gregarious, almost always encountered in single-species flocks of 3–15 individuals, sometimes more, or in groups that associate with canopy mixed-species flocks; regularly associated with *T. schrankii*, and the two species may forage together, either accompanying mixed flocks or travelling independently of them. Moves in and out of slower-moving mixed-species flocks, sometimes remaining for only a few minutes before flying off, abandoning a mixed flock. Forages mainly very high up, averages 25–50 m above ground, only infrequently dropping low along forested edges to reach fruiting shrubs. Groups restless and active, individuals searching rapidly on high open branches almost exclusively by hopping outwards and leaning downwards, first along one side of a branch and then the other, to check sides and undersurface; searches both bare and mossy branches. Also searches in foliage for small berries.

Breeding. In Peru, breeding recorded in Jun–Sept in SE and nest-building observed in Nov in C (Pasco); nest reported in Oct in French Guiana. Nest in SE Peru a small cup built mostly by female, both adults visited during construction but only one (presumably female) carried material, including green lichen-like moss, a fungus (*Rhizomorpha corynephora*), fluff from seeds like those of dandelion (*Taraxacum*), possibly spider web, and straw-like grass lining, placed 31 m up in small outer branch fork of *Ceiba pentandra* tree; no information on clutch size, incubation stints variable, 15–55 minutes, incubation period less than 16 days; nestlings fed by both parents, by which time tree had lost all its leaves and nest was exposed; nest ultimately failed following disturbance (unknown causes); c. 1 month later a second nest was under construction in same tree, disappeared after 8 days. In Brazil, cup-nest 5–20 m above ground reported; eggs apparently white or greenish-white with lilac and purplish-red markings, especially around large end. No further information available.

Movements. Resident.

Status and Conservation. Not globally threatened. Widespread, and fairly common to common. Found in many protected areas, and widely distributed in unprotected areas. This species does not face any immediate threats, although it suffers adverse impact locally from destruction of Amazonian rainforest.

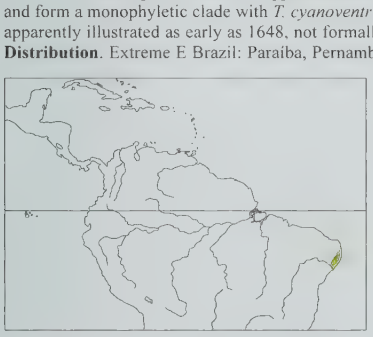
110. Seven-colored Tanager



Tangara fastuosa

French: Calliste superbe **German**: Vielfarbentangare **Spanish**: Tangara Sietecolores

Taxonomy. *Tanagra fastuosa* Lesson, 1831, Pernambuco, Brazil.

Recent molecular-genetic studies suggest that this species and *T. seledon* are likely sister-species and form a monophyletic clade with *T. cyanoventris*, *T. cyanocephala* and *T. desmaresti*. Although apparently illustrated as early as 1648, not formally described until 183 years later. Monotypic.

Distribution. Extreme E Brazil: Paraiba, Pernambuco and Alagoas.

Descriptive notes. 13 cm. A brilliantly coloured and boldly patterned tanager, with bill relatively thick for the genus. Has narrow black ocular ring and line surrounding base of bill; otherwise, entire head to hindneck and upper throat bright greenish-turquoise, mantle and scapulars deep black, back, rump and uppertail-coverts bright burnished yellow-orange; tail feathers black, edged deep blue; lesser upperwing-coverts turquoise-blue, median coverts cobalt-blue, greater coverts black, broadly edged deep violet-blue, flight-feathers black, edged dark blue, tertials black, broadly edged orange-yellow on outer webs; lower throat black, the black extending narrowly onto side of neck to meet black of back; chest light blue, shading to deep ultramarine-blue on lower breast, belly and undertail-coverts; iris dark brown; bill black; legs dark grey. Sexes similar. Juvenile undescribed. Voice. In disputes or when excited, a high "ti-ti-ti-ti", much like that of many congeners. No other information.

Habitat. Humid floodplain-forest and upland forest, forest borders and older second-growth woodland in lowlands and foothills, to c. 1000 m. Occurs also in degraded habitat composed predominantly of *Cecropia* and *Parkia*, although long-term viability in such habitats unknown. Possibly also in somewhat drier, more open habitat (*cerrado*); confirmation needed.

Food and Feeding. Fruits and arthropods One stomach contained vegetable matter. Occurs in pairs and in small groups, often with mixed-species flocks, staying mostly in upper levels and canopy, but descending low along forest borders and in young second growth, gardens, and orchards with bromeliads. Searches for insects by hopping along branches and peering down on one side and then the other. Behaviour similar to that of *T. chilensis* and *T. seledon*.

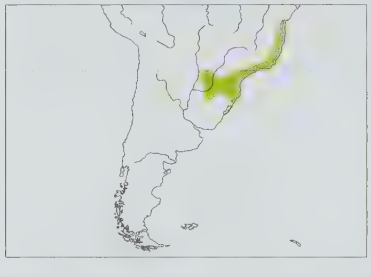
Breeding. Breeding reported in Oct–Mar (austral spring and summer). Nests reported in forest middle storey, usually in large bromeliads, which could be keystone plants in breeding requirements. No other information.

Movements. Resident.

Status and Conservation. VULNERABLE. Restricted-range species: present in Atlantic Slope of Alagoas and Pernambuco EBA. Uncommon to rare; declining within its very small global range. Confirmed sites (more than 50) for this species are in areas of Atlantic Forest. It has been recorded also in Rio Grande do Norte (at Capim Macio and Parque das Dunas Costeiras, and Baía Formosa), but these sites are *cerrado*, a significantly different habitat from those where the species has been found previously; records possibly involve escaped cagebirds. As late as 1987, the species was still relatively numerous in forests of Serra Branca, near Murici, in Alagoas. Since then it has declined steadily, as a result of severe deforestation coupled with trapping for cagebird trade. Estimated that no more than 2% of original Atlantic Forest remains in NE Brazil, the consequence of logging, and conversion to sugar-cane plantations and cattle pastures; few, if any, forest tracts larger than 4000 ha remain in this area, and sites are threatened by fires from adjacent plantations and by new roads (which facilitate logging). Intense trapping also continues, because of high price commanded by this species in trade. These factors, combined with its extremely limited range, place this species at significant risk. Known to occur in a number of protected areas, including Dunas de Natal State Park, Charles Darwin Ecological Refuge, Mata do Pau Ferro Ecological Park, Serra dos Cavalos UFPE and Tapacurá Ecological Stations, and Saltinho and Pedra Talhada Biological Reserves. Reforestation projects underway in Pedra Talhada and elsewhere may eventually increase the area of available habitat.

Bibliography. Anon. (2010a), Burns & Naoki (2004), Butchart & Stattersfield (2004), Carvalho (1986), Forbes (1881), Isler & Isler (1999), Lamm (1948), Ridgely & Tudor (1989, 2009), Sedano & Burns (2010), Sick (1985, 1993), Silveira *et al.* (2003), Souza (2002), Stattersfield & Capper (2000).

111. Green-headed Tanager



Tangara seledon

French: Calliste à tête verte **German**: Dreifarbentangare **Spanish**: Tangara Arcoiris

Taxonomy. *Tanagra Seledon* Statius Müller, 1776, Cayenne; error = Rio de Janeiro, Brazil.

Recent molecular-genetic studies suggest that this species and *T. fastuosa* are likely sister-species and form a monophyletic clade with *T. cyanoventris*, *T. cyanocephala* and *T. desmaresti*. Monotypic.

Distribution. SE Brazil (from SE Bahia S to Santa Catarina and NE Rio Grande do Sul) and adjacent parts of SE Paraguay (Alto Paraná) and NE Argentina (Misiones).

Descriptive notes. 13 cm; mean 18·7 g (nine birds from Paraguay), two others 16 g and 20 g. Brightly coloured tanager with complex plumage pattern reminiscent of that of *T. chilensis* and *T. fastuosa*, but greener and more pastel. Male has narrow black line surrounding bill and narrow black orbital ring; otherwise, entire head, nape and chin bright aquamarine-green, broad band across nape and wrapping around on sides of neck to throat shining pale lime-green (varying to burnished yellowish-green); back and scapulars mostly black, rump burnished yellow-orange, uppertail-coverts bright apple-green; tail black, edged pale green basally, changing to turquoise-blue distally; upperwing-coverts rich dark violet-blue, alula and primary coverts black, edged violet-blue on outer webs; flight-feathers black, broadly edged light green; lower throat and central upper chest black, which extends variably over side of chest; breast and central belly bright turquoise-blue, sides of belly, flanks and undertail-coverts bright apple-green; iris dark brown; bill black; legs dark grey to black. Female is similar to male or slightly duller. Immature is much duller than adult. Voice. Call a high, slightly buzzy "zweet" with rising inflection, and sometimes followed by other excited notes, e.g. "zwéé-dit, zwéé-dit-see" or "zwéé-di-di-di-dit", and other twittering notes. Dawn song, from crown of tree, a high-pitched, steadily repeated, trisyllabic "sít sir zwéét", up to 90 in a minute.

Habitat. Found in canopy of humid forest, along forest borders, in small clearings with scattered trees and shrubs, and in second growth of various ages, also parks, gardens and around human dwellings. Lowlands to c. 900 m; most numerous at low elevations.

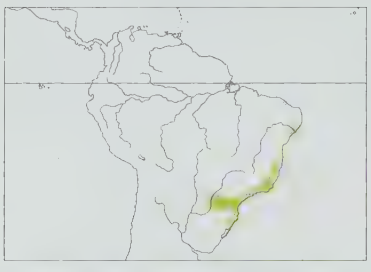
Food and Feeding. Fruits, also arthropods. Takes wide variety of cultivated fruits, including oranges, papayas (*Carica papaya*) and bananas, as well as many wild fruits, such as figs (*Ficus*), *Hamelia*, *Urtica*, and berries from bromeliads; in Paraguay observed to eat fruit of *Allophyllus edulis*. Of six stomachs examined, five contained only vegetable matter and one only animal matter; contents included fruit and ants (Formicidae). Occurs in pairs and in small groups, sometimes in larger groups containing up to 20 individuals; pairs or groups forage alone or associate with mixed-species flocks. Forages mostly from middle heights to canopy (c. 9–25 m up) in forest, sometimes lower along forest borders and in disturbed areas. Foraging behaviour versatile; often employs acrobatic movements when hopping along branches, or peering and gleaning from leaf surfaces, bark, lichens and epiphytes, and regularly leans down to inspect sides of bare branches. In Paraguay obtained fruit of *Allophyllus edulis* mostly by perching and reaching for fruits, which it often manipulated with bill to remove seeds or soften pulp. Will visit feeding trays.

Breeding. Season Nov–Feb in Brazil, and recorded in Nov and Dec in Paraguay and Nov in NE Argentina; apparently, second brood often attempted shortly after completion of first. Nest reportedly built by both sexes, a compact cup of grass and leaves, lined with softer material, and concealed in foliage of tree or shrub, in bromeliad along side of trunk or among epiphytic orchids on limb; nests also reported in mature banana plants. Clutch usually 3 eggs (once 2), white or pinkish-white with various shades of brown and grey markings, especially at large end; no information on incubation and nestling periods in the wild; young from first and second broods may accompany adults for most of first year. In captivity: incubation period reported as 17 days; young leave nest after 30–35 days, but fed by parents up to 75 days.

Movements. Resident. Possible seasonal movements between forest and semi-open areas reported.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Despite occurrence in variety of disturbed and second-growth habitats, this species has, since late 1980s or earlier, disappeared from large areas of recently deforested terrain, and is also absent from remnant woodlots studied in São Paulo state of SE Brazil; this suggests that total numbers are much reduced and distribution highly fragmented. Viable populations now confined mainly to protected areas, among them Sooretama, Poço das Antas and Augusto Ruschi (Nova Lombardia) Biological Reserves and Itatiaia, Tijuca, Serra dos Órgãos and Iguaçu National Parks (Brazil) and Iguazú National Park (Argentina).

Bibliography. Athanas (2010a), Belton (1974), Bertoni (1901), Burns & Naoki (2004), Descourtilz (1852), Diamond & Lovejoy (1985), Euler (1867, 1900), Goeldi (1894), Hempel (1949), Isler & Isler (1999), Mitchell (1957), Narosky & Di Giacomo (1993), Nehrkorn (1899), Norgaard-Olesen (1973), de Oliveira & Rech (1981), de la Peña & Rumboll (1998), Ridgely & Tudor (1989, 2009), Sazima *et al.* (1993), Sedano & Burns (2010), Sick (1985, 1993), Snethlage & Schreiner (1929), Souza (2002), Vigil (1973), Willis (1979).



112. **Red-necked Tanager**

Tangara cyanocephala

French: Calliste à tête bleue **German**: Blaukappentangare **Spanish**: Tangara Militar

Taxonomy. *Tanagra cyanocephala* Statius Müller, 1776, Cayenne; error = Rio de Janeiro, Brazil.
Based on molecular-genetic studies this species forms a monophyletic clade with *T. fastuosa*, *T. seledon*, *T. cyanoventris* and *T. desmaresti*. Three subspecies recognized.

Subspecies and Distribution.
T. c. cearensis Cory, 1916 – Ceará, in NE Brazil.
T. c. corallina (Berlepsch, 1903) – Pernambuco and adjacent N Bahia, in E Brazil.
T. c. cyanocephala (Statius Müller, 1776) – SE Brazil (from Espírito Santo S to Rio Grande do Sul), SE Paraguay (Canindeyú) and adjacent NE Argentina (Misiones).

Descriptive notes. 13 cm; 16–21·6 g. Unmistakable, brilliantly patterned tanager with green underparts and red nuchal area. Male nominate race has forehead and lores down to chin black, black orbital ring dotted turquoise; upper forehead and ring around eye shining turquoise, crown glistening violet-blue, bright deep red to scarlet band across nape continuing forwards across ear-coverts and cheek, and narrowing onto upper throat; mantle and scapulars deep black, rump and uppertail-coverts bright green; tail feathers dusky, edged and tinged green; lesser upperwing-coverts jet-black, median coverts mostly coppery gold (forming small but conspicuous band), greater coverts black, broadly and extensively edged bright green; basal half of outer flight-feathers and all of inner flight-feathers and tertials broadly edged bright green; small central throat area blackish, becoming violet-blue on lower throat and bright glistening blue across central chest; rest of underparts, including undertail-coverts, bright glistening green; iris dark brown; bill black; legs dark grey to black. Female is similar to male, but much duller (lacking glossiness), has crown dull blue, back greenish with heavy black mottling, nape band duller red, chin black, throat dusky with faint blue tinge. Juvenile resembles adult but much duller. Race *cearensis* differs from nominate in having crown blue (less violet-tinged), nuchal band less deep red, lower throat cobalt-blue (not violet-blue) and uppertail-coverts glistening turquoise-blue, female like nominate but throat more strongly tinged blue and bordered below by narrow band of brighter blue on chest, belly tinged yellowish-buff; *corallina* differs from previous in having small patch on throat dark blue, turquoise around eye extends backwards as eyebrow, uppertail-coverts intermediate in colour between those of other races. Voice. Call a high, sharp "seet!" and softer "sip", either note sometimes in a series accelerating into a trill; also a high, sharp "tsit-tsit-tsit". Song possibly a rapid twitter, or the series of notes that quicken to a trill.

Habitat. Forest-based species found in canopy, forest borders, light woodland and second growth, and sometimes in urban parks; also occurs in scrub or *caatinga* in N part of range. To 1000 m or more.

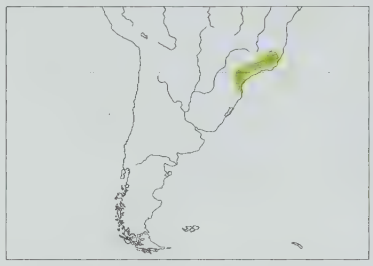
Food and Feeding. Fruit supplemented by some insects; reported food items include *Phytolacca*, melastome berries, *Urtica*, and myrtle. Occurs in pairs and in lively little parties up to about seven individuals; in forested areas regularly with mixed-species flocks containing others of its genus, but in drier, scrubbier N portions of range (where few such flocks) singles or pairs are usually alone. Searches rapidly, mostly quite high in forest, but will descend low to fruiting shrubs.

Breeding. All information from observations of captives. Deep, grassy cup-nest; clutch 3 eggs, whitish with brownish spots, mostly at larger end; incubation entirely by female, period 12–13 days; both adults fed young, which left nest at 15 days and were fed by adults for a further three-and-a-half weeks.

Movements. Resident.

Status and Conservation. Not globally threatened. Status not well known; common in some places. Range highly fragmented, with four isolated populations, and total numbers now substantially reduced from former levels. Populations once contiguous across S Brazil W to Paraguay and Argentina, but now separate. Still thrives in some numbers in main coastal parts of range, i.e. in Augusto Ruschi (Nova Lombardia) Biological Reserve, in Espírito Santo, and Serra dos Órgãos and Tijuca National Parks, above Rio de Janeiro. In addition, this species is capable of utilizing some second-growth and disturbed habitats.

Bibliography. Athanas (2010a), Burns & Naoki (2004), Davis (1945b, 1946), Descourtilz (1852), Diamond & Lovejoy (1985), Dunning (1982), Forbes (1881), Hamilton (1871), Isler & Isler (1999), Lamm (1948), Mitchell (1957), Norgaard-Olesen (1973), Parker & Goerck (1997), de la Peña & Rumboll (1998), Pinto (1954), Ridgely & Tudor (1989, 2009), Sazima *et al.* (1993), Sedano & Burns (2010), Sick (1985, 1993), Sick & Pabst (1968).



113. **Brassy-breasted Tanager**

Tangara desmaresti

French: Calliste de Desmarest **German**: Orangebrusttangare **Spanish**: Tangara de Desmarest
Other common names: Gould's Tanager ("*T. gouldi*")

Taxonomy. *Tanagra Desmaresti* Vieillot, 1819, Rio de Janeiro, Brazil.
Based on molecular-genetic studies this species forms a monophyletic clade with *T. fastuosa*, *T. seledon*, *T. cyanocephala* and *T. cyanoventris*. Described form *T. gouldi* appears to be a hybrid between present species and *T. cyanoventris*. Monotypic.

Distribution. Coastal SE Brazil from SE Minas Gerais, Espírito Santo and Rio de Janeiro S through E São Paulo, E Paraná and E Santa Catarina.

Descriptive notes. 13 cm; 19–21·5 g. Colourful, predominantly green tanager with blue on face and large golden patch on throat and chest. Has narrow area around bill and well-defined ocular ring black; otherwise, forehead (rather diffusely demarcated), lores and broad ocular area turquoise, mid-crown to nape, side of neck, mantle and back bright yellowish apple-green, crisply streaked black, rump and uppertail-coverts plain green; tail feathers blackish, broadly edged green; bend of wing and lesser upperwing-coverts brassy golden (often partly hidden), median coverts dusky, broadly edged and tipped brassy golden, greater coverts black, sharply edged and tipped apple-green, flight-feathers black, edged green; side of head green (unstreaked), throat yellow, with rounded black spot in centre of lower throat, below which is a triangular brass-gold area reaching down onto mid-breast; rest of underparts mostly bright green, narrow buff-yellow median line down breast and belly; undertail-coverts mostly yellow, tinged green; iris dark brown; bill black; legs dark horn-grey. Sexes similar. Immature is like adult, but much duller. Voice. Contact note a high, thin "tseee" or abrupt "tsit!", singly or repeated rapidly in short series. Also gives rapid chittering trill, and groups may call noisily at times.

Habitat. Found mainly in humid pre-montane and montane forest and at forest edge, less often in second growth and clearings with scattered trees. Recorded at 500–2200 m, but mostly at 800–1800 m.

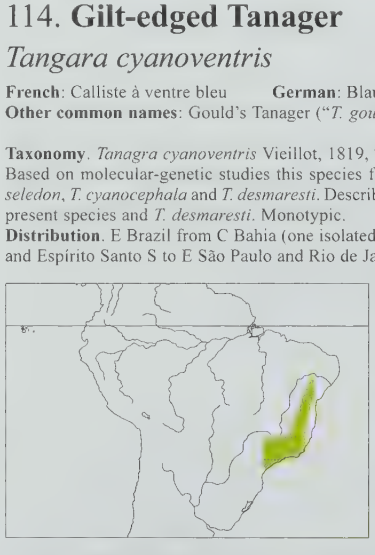
Food and Feeding. Mostly fruits, some arthropods. Reported items include melastome berries, *Urtica* and myrtle. One stomach contained only vegetable matter. Food items brought to nestlings included spiders (Araneae), seed masses, an orthopteran nymph, caterpillar, planthopper nymphs (Fulgoroidea), katydid nymph (Tettigoniidae) and unidentified winged insect. Markedly social, occurring in pairs, families and monospecific groups of up to about a dozen individuals; frequently found with mixed-species flocks, but moves rapidly and may at times leave slower-moving species behind. Agile, often forages on slender branches within foliage near tip of branch. Of 41 observations of foraging: 16 involved leaf-gleaning; eight were sallies to foliage; seven sallies to air; eight involved scanning and picking at lichens and moss; remainder undocumented. Occasionally forages for arthropods by hopping quickly along limbs, leaning head downwards first on one side of a branch and then on other to inspect surfaces as it progresses outwards; also actively hops and peers in foliage.

Breeding. Nest in Jan and another in Feb in Rio de Janeiro (Itatiaia massif). Both sexes bring nest material, but one assumes majority of construction work; nest a deep, thick-walled cup (9 × 8 cm outer diameter) made from dry bamboo leaves (of both native and introduced species), thin twigs, rachises of compound leaves, rootlets, lichen, fungal rhizomorphs, cocoons and spider silk, one nest with moss on outside; 0·5–9 m above ground, one well anchored in multiple-branched fork of tree, two in branched nodes of bamboo, often in man-made clearing. No information on clutch size; eggs whitish, speckled with fine grey spots; male may feed sitting female, incubation period 12–13 days. No other information.

Movements. Resident; possibly some movement in Espírito Santo.

Status and Conservation. Not globally threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Locally fairly common. Confined mainly to montane regions where remnant forest patches remain. Occurs in numerous protected areas, among them Serra dos Órgãos National Park, in Rio de Janeiro, Patrimônio Natural Special Reserve, in Minas Gerais, and Itatiaia National Park, on border between those two states. Outside protected areas, this species is regarded as highly vulnerable because of severe forest loss within its limited range.

Bibliography. Belcher & Smooker (1937), Bond (1947), Burns & Naoki (2004), Davis (1945b, 1946), Descourtilz (1852), Diamond & Lovejoy (1985), Gagliardi (2007b), Gonzaga & Castiglioni (2006), Hellmayr (1936), Hempel (1949), Holt (1928), Isler & Isler (1999), McCarthy (2006), Meyer de Schauensee (1966, 1970a), Parker & Goerck (1997), Pinto (1944a, 1951), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Sazima *et al.* (1993), Sclater (1886), Sedano & Burns (2010), Sick (1985, 1993), Souza (2002), Steinbacher (1938).



114. **Gilt-edged Tanager**

Tangara cyanoventris

French: Calliste à ventre bleu **German**: Blaubrusttangare **Spanish**: Tangara Ventriazul
Other common names: Gould's Tanager ("*T. gouldi*")

Taxonomy. *Tanagra cyanoventris* Vieillot, 1819, "Brésil" [Brazil].
Based on molecular-genetic studies this species forms a monophyletic clade with *T. fastuosa*, *T. seledon*, *T. cyanocephala* and *T. desmaresti*. Described form *T. gouldi* appears to be a hybrid between present species and *T. desmaresti*. Monotypic.

Distribution. E Brazil from C Bahia (one isolated record from extreme N Bahia), S Minas Gerais and Espírito Santo S to E São Paulo and Rio de Janeiro.

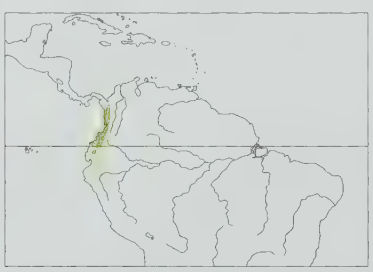
Descriptive notes. 13 cm; 16–20 g. Colourful tanager, mostly golden above and blue below, with golden head. Has narrow area surrounding bill and thin orbital ring jet-black; otherwise, entire head, including chin and side of throat, and upperparts golden-yellow, crown, nape and rear side of neck to back streaked black; tail feathers black, edged green; lesser upperwing-coverts mostly bright green (usually concealed), median and greater coverts dusky, edged green, primary coverts and flight-feathers black, edged green, tertials mostly green with dusky inner webs; central throat black, breast and sides turquoise-blue, centre of lower breast and belly yellowish-green, undertail-coverts yellow to yellowish-green or pale yellow-buff; iris dark brown; bill black; legs dark grey. Sexes similar, female tends to be duller. Juvenile undescribed. Voice. Abrupt sharp call notes include "tsit" and "seet!", which may accelerate into chittering trill; also a lower-pitched "chip" or "chup", also sometimes accelerating into short bursts or trills.

Habitat. Humid pre-montane forest and forest borders, to lesser extent also second-growth woodland and overgrown clearings. Lowlands to 1200; now mostly above 500 m.

Food and Feeding. Diet includes both fruit and some insects. Recorded fruit items include melastome berries and fruit of *Urtica*. Lives in pairs and in small groups of up to about eight individuals, often found with mixed-species flocks containing others of genus; possibly not so often in large monospecific groups as is *T. desmaresti*. Forages from middle heights up to canopy in forest, but descends lower along forest edges to exploit fruiting shrubs. Searches for insects mostly by hopping among small slender outer twigs and peering in terminal foliage; occasionally also checks curled green leaves. Behaviour much like that of forest-based congeners of SE Brazil.
Breeding. A nest found in Nov in Rio de Janeiro was 12 m up in fork of tree; nest possibly lined with strips of bamboo. Offspring of a previous brood have been seen to act as helpers at nest. No other information.

Movements. Resident.
Status and Conservation. Not globally threatened. Locally common. Range now much fragmented, and numbers substantially reduced. Survives in remaining forested areas in SE coastal range, and (as with many other SE Brazil endemics) bulk of population may now be confined largely to protected areas. Considered still common at several reserves, including Augusto Ruschi (Nova Lombardia) Biological Reserve, in Espírito Santo, and Itatiaia National Park, in Rio de Janeiro.
Bibliography. Dunning (1982), Erickson & Mumford (1976), Hellmayr (1936), Holt (1928), Isler & Isler (1999), McCarthy (2006), Meyer de Schauensee (1966, 1970a), Mitchell (1957), Parker & Goerck (1997), Pinto (1951), Remsen *et al*. (2010), Ridgely & Tudor (1989, 2009), Sclater (1886), Sedano & Burns (2010), Sick (1985, 1993), Skutch (1961), Souza (2002).

115. **Blue-whiskered Tanager**



Tangara johannae

French: Calliste moustachu **German**: Blaubarttangare **Spanish**: Tangara Bigotuda

Taxonomy. *Calliste johannae* de Dalmas, 1900, El Paillon [= Estero Pailón], near Buenaventura, Valle, Colombia.

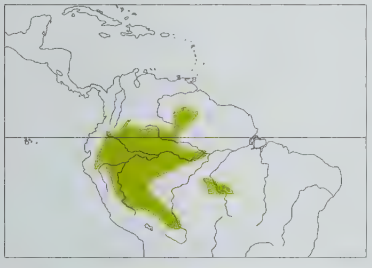
Genetic data indicate that this species is part of a monophyletic species group that includes also *T. schrankii*, *T. florida*, *T. arthus*, *T. icterocephala*, *T. xanthocephala*, *T. chrysotis* and *T. parzudakii*. Monotypic.

Distribution. Colombia (W slope of W Andes from Mutatá, in W Antioquia, and C Chocó) S to W Ecuador (Pichincha, once to Los Ríos).

Descriptive notes. 13 cm. Small tanager with green body, black face and throat, and conspicuous blue malar. Has face, including lores, area around eye, side of head and throat black, surrounded anteriorly by variable narrow turquoise border; prominent large turquoise malar patch separating black of face from black of throat; rest of plumage mainly bright apple-green with golden tinge, forecrown sometimes faintly flecked with black, mantle and back streaked black, rump plain bright yellow, longer uppertail-coverts dusky, edged and tipped green; tail black, feathers edged turquoise broadly at base and more narrowly near tip; upperwing-coverts black, narrowly edged turquoise-blue, a few innermost greater coverts often somewhat edged green; flight-feathers black, outer ones prominently edged blue, inner ones and tertials edged green; base of black throat with narrow edge of blue (usually concealed); breast and lower underparts mainly bright apple-green, centre of belly and undertail-coverts greyish to buff; iris dark brown; bill black; legs dark horn-grey. Sexes similar, female often slightly duller than male. Juvenile is very dull and largely without distinctive pattern or bright colour; immature similar to adult, but duller. Voice. Call or contact note during foraging a shrill buzzy "tzzeee", similar to that of *T. arthus*. No song has yet been described.

Habitat. Canopy and borders of wet forest to pluvial forest, older second growth, forest regrowth around landslides, and slashed clearings. Lowlands to c. 700 m, rarely to 1000 m.

Food and Feeding. Fruits, some arthropods. Occurs in pairs or in family groups of 3–4 individuals,



and a regular member of mixed-species flocks. Forages mainly at middle levels or higher in forest, occasionally lower along forest borders. Visits variety of small to large fruiting trees and shrubs for fruit. Forages for insects by moving in little spurts along relatively slender mossy or bare limbs, then pausing briefly and leaning head downwards to inspect first one side (or underside) of a branch and then the other; distinctive "stereotyped" movements resemble those of many congeners.
Breeding. One adult carrying food to a cup-nest on high mossy limb in Jan in Colombia (W Valle). No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Chocó EBA. Rare to uncommon, locally fairly common. Generally occurs at rather low density, but has been reported as fairly common at Río Ñambí Natural Reserve, in SW Colombia. May occur in Utría and Sanquianga National Parks, in Colombia; possibly also in Cotocachi-Cayapas Ecological Reserve, in NW Ecuador, but otherwise few protected sites within its limited range. Is able to use various age-stages of second growth, and its range includes (or formerly included) considerable intact lowland forest. Believed to be in moderate to rapid decline because of loss of forest habitat in Chocó–Pacific lowlands, which have, in recent decades, been besieged by logging, clear-cutting for cattle pastures, gold-mining, palm and coca cultivations, and illegal farming activities.
Bibliography. Anon. (2010a), Burns & Naoki (2004), Butchart & Stattersfield (2004), Haffer (1967a, 1975), Hilty & Brown (1986), Isler & Isler (1999), Jahn *et al.* (2002), Renjifo *et al.* (2002), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sedano & Burns (2010), Stattersfield & Capper (2000).

116. Green-and-gold Tanager

Tangara schrankii

French: Calliste de Schrank **German**: Goldbrusttangare **Spanish**: Tangara de Schrank

Taxonomy. *Tanagra schrankii* Spix, 1825, no locality = Tabatinga, River Solimões, Brazil.
Genetic data indicate that this species is part of a monophyletic group that includes also *T. johannae*, *T. florida*, *T. arthus*, *T. icterocephala*, *T. xanthocephala*, *T. chrysotis* and *T. parzudakii*. Taxon *anchicayae*, described from mountains above R Anchicayá, in Valle (Colombia), erroneously as a race of present species, is now known to be referable to *T. florida*. Two subspecies recognized.
Subspecies and Distribution.
T. s. venezuelana Phelps, Sr & Phelps, Jr, 1957 – S & SE Venezuela (E & S Amazonas and S Bolívar from upper R Caura E to upper R Caroní).
T. s. schrankii (Spix, 1825) – SE Colombia (from Caquetá and Vaupés) S through E Ecuador and E Peru to EC Bolivia (Santa Cruz), and E in Brazil (mostly S of R Amazon) to E Amazonas and extreme NW Mato Grosso.

Descriptive notes. 12 cm; 14–23 g. Colourful green, yellow and black plumage. Male nominate race is mainly bright emerald-green; forehead, supraloral line and narrow area around eye black, this extending into large squarish to triangular black patch on ear-coverts, pale bright turquoise crescent in front of eye, and narrow, bright turquoise margin behind black ear-coverts; mid-crown bright yellow, nape and side of neck (behind black patch) green to golden-green (depending upon light), flecked and mottled with black (imparting obscure scaled appearance); mantle and back bright emerald-green, broadly streaked black, rump and uppertail-coverts bright yellow with faint greenish tinge; tail blackish, edged green to greenish-blue; upperwing-coverts, primary coverts, flight-feathers and tertials black, lesser and median coverts heavily edged and tipped turquoise-blue, outermost greater coverts edged blue and inner ones edged bright green, primaries edged turquoise, secondaries and tertials edged green; chin black, upper throat and underparts mainly bright emerald-green, lower throat and all of central breast to belly bright yellow; undertail-coverts buff, somewhat mixed dull green; iris dark brown; bill black; legs dark horn-grey. Female is similar to male, but slightly duller, with crown greenish, flecked black, yellow on rump reduced. Juvenile is dull greyish-brown with little of adult pattern evident; immature similar to adult, but yellow and green of plumage very dull. Race *venezuelana* is much like nominate, differing in having yellow of rump slightly less extensive and brighter yellow. Voice. Calls and contact calls are high, thin "chit" and "tsi" notes, often uttered rapidly and sometimes in excited bursts, e.g. "tsi-ti-ti-ti-ti-ti-...tsi-ti-ti-ti-ti-ti-...". Song, at dawn, one to several weak, high-pitched trills, the notes run together and blurred, "t-ttttttt...ttttttt..ttttttt...". a possible variation includes a series of lower-pitched, more chattery trills mixed with occasional "chat" notes.
Habitat. Humid *terra firme* and *várzea* forest in lowlands, and decreasing numbers in humid and wet foothill forest; less often along forest borders, and only occasionally in scattered trees in clearings. Lowlands mainly to c. 1200 m; to 900 m in Venezuela and to 1600 m in Peru.
Food and Feeding. Fruits, especially *Cecropia*, also some arthropods. Of 17 stomachs examined, 14 contained only vegetable matter and two only animal matter and one held both; contents included fruit, seeds and insects. Occurs in pairs when breeding, but otherwise typically in small to fairly large groups, sometimes of up to 20 individuals, or even more, when with canopy flocks; regularly associates with mixed-species flocks, both in canopy and, sometimes, much lower; also a regular associate of *T. chilensis*, the two frequently foraging together away from mixed flocks. Sometimes found in forest understorey when canopy and understorey flocks join up temporarily. Forages by hopping rapidly along larger horizontal branches, where it leans with head down, first on one side of a branch and then on other, to inspect sides and undersurfaces of branches. In Bolivia, 18 observations of insect-foraging from leaves included nine with acrobatics, seven without acrobatics, and two by hovering; also noted as sallying to air, and hanging downwards to glean from branch. In Peru, six observations included gleaning from undersurface of slender branches, three by hanging to glean from beneath leaves, and once from uppersurface of a leaf. Occasionally checks dead leaves.
Breeding. Few nests found, in Jul, Aug and Oct in Peru; females in breeding condition Jul–Dec (but very few specimens Dec–May). Nest cup-shaped, made from dried leaves, lined with plant fibres and rootlets (sometimes mixed with dry leaves), external diameter 10·2–11 cm and height 8–12·2 cm, internal diameter 4·3–6 cm, depth 5–6·6 cm, placed 75 cm to 2 m above ground at base of understorey plant, e.g. at base of *Geonoma* palm frond or beneath base of *Asplenium serratum* fern, woven to plant and generally well concealed by overhanging vegetation or the like; also recorded nesting in hollow of rotting trunk. Clutch 2 eggs, pale reddish-brown with dense darker red speckles; at one nest, female laid replacement clutch after first brood preyed on, apparently by Slate-coloured Hawk (*Leucopternis schistacea*), incubation of replacement 15–17 days, no information on duration of nestling period.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Widespread and common across much of W Amazonia. Occurs in a number of large protected areas, among them Canaima National Park (Venezuela), Amacayacu National Park (Colombia), Cuyabeno Wildlife Reserve (Ecuador), Manu National Park (Peru), Madidi National Park (Bolivia) and Serra do Divisor National Park (Brazil). Within this species' range there also is extensive intact forest which is unprotected, but at little risk.
Bibliography. Athanas (2010a), Burns & Naoki (2004), Dunning (1982), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Lehmann (1957), Marra (1990), Mee *et al.* (2002), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Moore *et al.* (2009), Munn & Terborgh (1979), Novaes (1957), Parker *et al.* (1982), Pearson (1975b), Phelps & Phelps (1950, 1963), Remsen *et al.* (1987), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sick (1985, 1993), Souza (2002), Terborgh & Weske (1969, 1975), Van Houtan & Alvarez-Loayza (2006), Zimmer (1943b).

117. Emerald Tanager

Tangara florida

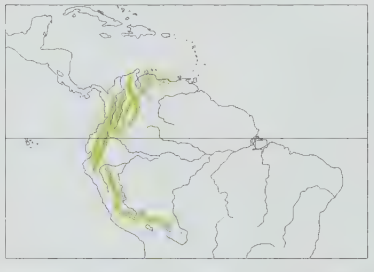
French: Calliste émeraude **German**: Smaragdtangare **Spanish**: Tangara Florida

Taxonomy. *Calliste florida* P. L. Sclater and Salvin, 1869, Costa Rica.
Genetic data indicate that this species is part of a monophyletic group that includes also *T. johannae*, *T. schrankii*, *T. arthus*, *T. icterocephala*, *T. xanthocephala*, *T. chrysotis* and *T. parzudakii*. Proposed race *auriceps* (described from Buenavista, in Nariño, in SW Colombia) considered indistinguishable from birds elsewhere in species' range. The form *anchicayae*, from mountains above R Anchicayá, in Valle (Colombia), described erroneously as a race of *T. schrankii*, is now known to be a synonym of present species. Monotypic.
Distribution. Caribbean slope of Costa Rica and Panama (E from Chiriquí and Veraguas; also Pacific coast in Darién) and Pacific coast of Colombia (S from S Chocó) to NW Ecuador (Imbabura, Esmeraldas and Pichincha).

Descriptive notes. 12 cm; 16·5–20·5 g. Small green-and-yellow tanager. Male has narrow black area encircling bill, narrow black orbital ring, and prominent squarish black patch on rear ear-coverts; upper forehead to nape yellow-green, purer yellow over most of crown; mantle and back glistening emerald-green, coarsely and boldly streaked black, rump unstreaked bright yellow, uppertail-coverts mostly glistening green (feathers dusky basally, tipped green); tail uniformly dull black above, outer feathers obscurely edged green (tail paler below); upperwing-coverts black, median coverts edged green, greater coverts broadly edged and tipped green, flight-feathers black, inner ones and tertials sharply edged green; throat and underparts mainly bright emerald-green, becoming yellow on centre of lower breast and belly and dull buff-yellow on crissum; iris dark brown; bill black; legs horn-grey. Female is similar to male, but somewhat duller green, and with crown green (not yellow) and belly duller yellow. Juvenile is almost entirely dull greyish-brown with little evidence of green-and-black adult plumage, but acquires hint of dusky markings on head and upperparts; immature also dull, but generally shows outline of adult markings; subadult male resembles female (age at which adult male plumage acquired unknown). Voice. Calls include raspy "jree" or "dzreee", penetrating and burrier than notes of *T. arthus* and *T. icterocephala*, and these sometimes given in accelerating series. Also, during foraging, weak "tsit" notes. Apparently sings only rarely; possible song, from branch c. 8 m up, a high burry "zeeeeee" note, louder than call, repeated regularly for up to several minutes with intervening pauses of c. 3 seconds.
Habitat. Humid and wet mossy forest and borders, and adjacent older second growth. Mostly foothills and lower elevations of mountains, at c. 500–1200 m in Costa Rica; at 100–1100 m in Colombia.
Food and Feeding. Fruits, some arthropods. Observed to eat berries of *Phytolacca*, *Schefflera* and *Trema* in Costa Rica. In Colombia fruit accounted for 71% of 468 observed foraging attempts, and 29 species of fruit were taken; *Miconia* berries accounted for 61% of all fruit eaten, *Cecropia* catkins comprised 10%, and holly (*Ilex*) 7% of fruit records. Contents of two stomachs were seeds and fruit. Occurs in pairs and in small groups usually associated with mixed-species flocks containing other tanagers (e.g. congeners, *Cyanerpes*). In W Valle del Cauca (Colombia), foraged from shrub tops to forest canopy, with median foraging height c. 9 m. Almost all fruit taken while bird perched. Also regularly searches in head-downward position from leaf petioles or from *Cecropia* catkins; regularly hung downwards from twigs or petioles next to berry clumps, such as those of *Ilex*, and was observed to eat flowers or flower buds of *Topobea brachyura*. Also in W Valle del Cauca, 95% of 116 records of arthropod-seeking were on moss-covered branches (rather than bare ones), where typically used a stereotyped leaning-the-head-down movement (73 of 97 records) to check first one side, then the other, of branches mostly 1·3–2·5 cm in diameter, a search strategy similar to that employed by many congeners. Also hung upside-down from branches or moss to reach hard-to-check sites in hanging moss clumps and underneath larger branches; may pull moss loose with bill to uncover arthropod prey. On one occasion several were observed foraging 0·3–2·4 m up over a swarm of highland *Labidus praedator* army ants in W Andes of Colombia.
Breeding. Two nests and a stub-tailed juvenile in Jan–Apr in Colombia; nest in Mar in Costa Rica. In Colombia a mossy cup nest, one on epiphyte-covered limb 8 m above ground and the other on moss-covered limb 12 m up; nest in Costa Rica only 1·5 m up in sapling in forest clearing. One adult brought food to nest in Costa Rica; in Colombia a pair observed to bring food (both insects and fruit). No other information.
Movements. Resident. In Costa Rica, some apparent seasonal movement to lower elevations during rainiest months when not breeding.

On following pages: 118. Golden Tanager (*Tangara arthus*); 119. Silver-throated Tanager (*Tangara icterocephala*); 120. Saffron-crowned Tanager (*Tangara xanthocephala*); 121. Golden-eared Tanager (*Tangara chrysotis*); 122. Flame-faced Tanager (*Tangara parzudakii*).

Status and Conservation. Not globally threatened. Fairly common in Costa Rica and Colombia; more local in Panama. Can be found in a number of protected areas, including Braulio Carrillo and Tapantí National Parks (Costa Rica), Chagres and Darién National Parks (Panama), and Los Katíos National Park and probably El Pangan Nature Reserve and lower slopes of R Anchicayá (part of which is under protection) in Valle (Colombia). While considerable intact unprotected forest remains in its range, deforestation for cattle-raising, human settlement, gold-mining and various legal and illegal agricultural crops are creating intense pressure on the foothill habitat that this species requires.



Bibliography. van den Berg & Bosman (1984), Burns & Naoki (2004), Carriker (1910), Davis (1972), Dunning (1982), Garrigues & Dean (2007), Hilty (1974, 1981, 1997, 2009a), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1964, 1966, 1970a), Naoki (2003c), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sedano & Burns (2010), Slud (1964), Stiles & Skutch (1989), Wetmore *et al.* (1984).

118. Golden Tanager

Tangara arthus

French: Calliste doré **German**: Goldtangare **Spanish**: Tangara Dorada
Other common names: Perija Tanager ("*aurulenta* group"); Sclater's Tanager (*sclateri*); Beautiful Tanager ("*pulchra* group")

Taxonomy. *Tangara Arthus* Lesson, 1832, Caracas, Venezuela.
Genetic data indicate that this species is part of a monophyletic group that includes also *T. johannae*, *T. schrankii*, *T. florida*, *T. icterocephala*, *T. xanthocephala*, *T. chrysotis* and *T. parzudakii*. Races possibly represent more than one species, e.g. it has been suggested that nominate race may merit isolated treatment, being markedly different from all others. Other plumage groups include: *sclateri*; *aurulenta*, *occidentalis*, *goodsoni* and *palmitae*; and *pulchra*, *aequatorialis* and *sophiae*. Further research required. Race *palmitae* poorly differentiated from *aurulenta* and possibly better synonymized with it. Nine subspecies currently recognized.
Subspecies and Distribution.
T. a. arthus Lesson, 1832 – mountains of N & W Venezuela (from NW Lara and Sierra de San Luis, in Falcón, E to Distrito Federal and Miranda; Andes from S Lara S to N Táchira).
T. a. aurulenta (Lafresnaye, 1843) – NW Venezuela (Sierra de Perijá) and W slope of E Andes of Colombia (S from about latitude of Bogotá).
T. a. occidentalis Chapman, 1914 – W slope of C Andes and both slopes of W Andes (S to Nariño), in Colombia.
T. a. goodsoni E. J. O. Hartert, 1913 – W slope of Andes in Ecuador, and probably also NW Peru.
T. a. palmitae Meyer de Schauensee, 1947 – W slope of E Andes at La Palmita (Santander), in Colombia.
T. a. sclateri (Lafresnaye, 1854) – both slopes of E Andes of Colombia (from Boyacá and Santander S to Cundinamarca, and in Macarena Mts), probably also Andes of adjacent SW Venezuela (S Táchira).
T. a. aequatorialis (Taczanowski & Berlepsch, 1885) – E slope of Andes in Ecuador and adjacent N Peru (Chaupe).
T. a. pulchra (Tschudi, 1844) – E slope of Andes in Peru (from Chachapoyas S to Chanchamayo).
T. a. sophiae (Berlepsch, 1901) – E slope of Andes in SE Peru (S from Cuzco and Puno) S to Bolivia (La Paz and W Cochabamba).

Descriptive notes. 13 cm; 18·7–27·5 g. Beautiful Andean tanager with plumage of rich gold and black, but notable for complex plumage variation. Nominate race has head rich deep glistening orange-yellow, with narrow black line above bill, black lores, narrow black orbital ring, and also a large squarish to trapezoidal black patch on ear-coverts; mantle and back greenish-yellow, heavily and sharply streaked black, lower back and rump golden-yellow (slightly paler than head); upperwing black, coverts narrowly edged and more broadly tipped pale yellow, secondaries and tertials sharply but narrowly edged yellow, sometimes with greenish tinge; tail black, outer feathers narrowly edged greenish; throat golden-yellow, broad chestnut band across upper breast and continuing down sides and flanks, rest of underparts rich golden-yellow; iris dark brown; bill jet-black; legs dark horn-grey. Sexes similar, female usually slightly duller than male. Juvenile is very dull, but may show hint of black markings on head and back; immature similar to respective adult, but much duller. Races differ mainly in plumage pattern and tones, nominate the only one with chestnut breastband and sides: *aurulenta* differs from nominate in having entire underside from throat to undertail-coverts rich golden-yellow; *occidentalis* resembles previous, but edgings on wing-coverts and flight-feathers more golden-yellow, and entire head and underparts slightly darker and richer golden-yellow, underparts showing hint of tawny wash; *goodsoni* is much like *aurulenta*, but slightly paler golden-yellow; *palmitae* closely resembles previous two, but forecrown of male slightly more golden-orange; *sclateri* is much darker and overall more tawny on head, rump and underparts, but retains greenish to yellowish-green edgings on wing-coverts and flight-feathers; *aequatorialis* differs in having variable wash of tawny-rufous on throat and chest; *pulchra* has throat and chest rich rufous-chestnut (darker than last), fading to golden-yellow on lower underparts, also has crown and side of neck tawny; *sophiae* is like last, but crown and side of neck golden (not tawny). Voice. Call a buzzy "seet" or "bzeet", often given over and over during foraging. Possible song in Venezuela a forceful, rapid "chid-it, chid-id-id-it" or "chíd-id-id-it chup", with pauses of 2–6 seconds between phrases.
Habitat. Humid and wet montane forest and forest borders, sparingly extending into trees and second growth in clearings near forest. More of an interior-forest species than are many congeners, although, at least in Venezuela, regularly comes to forest borders and feeding trays. At 600–2500 m; most numerous c. 1000–2000 m.
Food and Feeding. Fruit, some arthropods; also flower parts. Of nine stomachs examined, eight contained only vegetable matter and one contained both vegetable and animal matter, including fruit, seeds and insects. In W Valle del Cauca, in Colombia, about half of diet is fruit (57% of 307 observations): at least 22 species of fruits recorded in diet, 59% of all fruit taken being melastomes, especially *Miconia* species (89% of all melastomes); other commonly eaten fruits included holly (*Ilex*), accounting for 13%, and *Cecropia* and figs (*Ficus*), each making up 12%. Ate flowers or flower parts (possibly immature ovaries) of *Topobea brachyura* (Melastomataceae), which accounted for 2% of all records of vegetable matter being consumed. Nestling diet in Ecuador included katydids (Tettigoniidae), unidentified insects, whole fruit and mashed fruit. Singly and in pairs when breeding, but at other times several, sometimes up to a dozen or more, forage with mixed-species flocks containing other members of genus, but not in single-species flocks; regularly gathers with other small frugivores at fruiting trees. Forages at middle level to canopy; median foraging height above ground in W Valle del Cauca was c. 10 m, rarely below 3 m. Forages by peering with head down alternately on one side of branch and then the other, behaviour typical of genus. Gleans more from mossy or partly mossy branches (usually not twigs or foliage), 76 of 102 observations involving branches 1·3–5 cm in diameter and 84% of all insect-foraging on mossy branches, 16% on bare limbs. Even near terminal part of branches searches twigs and moss, not leaves. Also occasionally hangs from or clings to sides of vines to search bark or moss. Took fruits mostly when in upright, perched position, also occasionally while hanging head down from petioles or catkins. Has been observed to peck pieces from larger fruits.
Breeding. One nest found at end Mar in Ecuador (in Mushullacta Community Forest Reserve, SW Galeras Mts, c. 8 km SE of Guamaní, in Pichincha); in W Colombia, nest-building observed Jul, Sept and Oct and begging juveniles in May on W slope of W Andes, begging juveniles in Jul and Aug on E slope of W Andes, also ten breeding-condition birds in Apr–Sept in N. In Ecuador, a cup-nest wedged in epiphytes on thick horizontal branch, c. 10 m up in subcanopy tree on steep slope; held two nearly naked chicks; of 68 observed visits, 20 (almost 30%) were by a trio of adult-plumaged birds, indicating helpers or co-operative breeding; remaining visits were by single individual or pair. In captivity, both sexes carried nest material, only female built nest; clutch 1–2 eggs, white, tinged pink, and with reddish-brown spots coalescing at large end; incubation by female, period 14–15 days; chicks fed almost entirely by female. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Widespread, and generally fairly common to locally common throughout range. Occurs in numerous protected areas, from Henri Pittier, Yacambú, Guaramacal, Sierra Nevada and Tamá National Parks (Venezuela), S to Manu National Park (Peru) and Madidi and Amboró National Parks (Bolivia). Some populations, especially in N portions of Andes, now reduced and fragmented by deforestation, but the species' range still includes considerable unprotected montane-forest habitat that is probably not at serious risk in the immediate future.

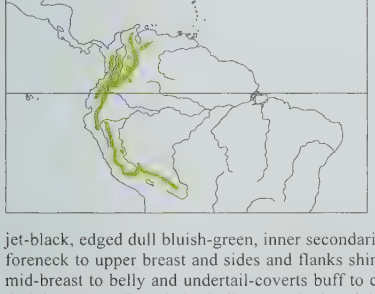
119. Silver-throated Tanager

Tangara icterocephala

French: Calliste safran **German**: Silberkehltangare **Spanish**: Tangara Goliplateada

Taxonomy. *Calliste icterocephala* Bonaparte, 1851, Punta Playa Valley, south of Quito, Ecuador.
Genetic data indicate that this species is part of a monophyletic group that includes also *T. johannae*, *T. schrankii*, *T. florida*, *T. arthus*, *T. xanthocephala*, *T. chrysotis* and *T. parzudakii*. Three subspecies recognized.
Subspecies and Distribution.
T. i. frantzii (Cabanis, 1861) – N Costa Rica S on both slopes of mountains to W Panama (Veraguas).
T. i. oresbia Wetmore, 1962 – mountains of WC Panama (Coclé and W Panamá).
T. i. icterocephala (Bonaparte, 1851) – mountains of Pacific slope of extreme E Panama (E Darién), and Andes of Colombia (W slope of C range in Antioquia; W slope of W range S from Antioquia) and W Ecuador (S to El Oro and W Loja); possibly also NE Peru (E Tumbes).

Descriptive notes. 13 cm; 17·7–24·7 g. Sleek, mostly bright yellow tanager with black moustachial stripe and silvery greenish-white throat. Nominate race has crown and upper nape to below eye bright golden-yellow, narrow yellow orbital ring; yellow of crown and side of head bordered below by long black moustachial stripe which extends from small black patch at bill base back to rearmost ear-coverts, becoming slightly broader towards rear; mid-crown to nape usually with hint of obscure greenish and black streaking (black bases of feathers showing through); partly concealed narrow band at base of nape bluish; mantle and back yellow, broadly streaked black, lower back to uppertail-coverts plain bright golden-yellow; tail feathers black, edged green, central feathers weakly tinged green; upperwing and its coverts black, lesser and median coverts faintly edged and broadly tipped yellow, greater coverts more broadly edged greenish to greenish-yellow, flight feathers and tertials edged green; throat silvery white often with faint greenish tinge, this colour extending outwards on to side of neck and down to chest; rest of underparts, including undertail-coverts, mainly bright golden-yellow; iris dark brown; bill black; legs dark grey. Sexes similar, female slightly duller than male (seldom apparent in field), with more greenish tinge, and sometimes some black mottling on crown. Juvenile is extremely dull and nondescript, dingy greyish-brown with little, if any, of adult plumage pattern evident; immature much duller than adult, often mainly dull greenish-olive above, with black wing and tail edged with greenish, and dingy greyish-olive below, with only centre of breast and belly yellowish; older immature has obvious pale throat and hint of black moustachial stripe. Race *frantzii* is much like nominate, but partly concealed narrow band at base of nape paler, pale greenish-blue, and foreneck and throat paler, more whitish; *oresbia* is darker than other races, decidedly darker yellow throughout, band on hindneck darker bluish-green, foreneck and throat darker, and sides and flanks darker with greenish-yellow cast, female has edging on back feathers greener, less yellowish. Voice. Call, during foraging and often in flight, a very buzzy "shreet" or "bzzeet", harsher than that of *T. florida* and *T. arthus*. No song yet described or recorded; song recordings attributed to this species require confirmation.
Habitat. Humid forest and wet forest, forest borders, and older second-growth woodland, in all areas favouring wet mossy forest; in Costa Rica regularly in scattered trees in clearings, but rarely away from forest in Colombia. At c. 600–1700 m, rarely to 2300 m, in Costa Rica, but nearly down to sea-level in rainiest months; c. 400–2100 m in Colombia and recorded at 150–1550 m (mainly 500–1350 m) in W Ecuador. In Andes numbers diminish rapidly above c. 1200 m, where replaced by *T. arthus*.



Food and Feeding. Fruits, flower buds, and some arthropods. Three stomachs contained only vegetable matter, including fruit and *Cecropia* seeds. In Costa Rica reported as commonly eating arillate fruits of epiphytic vine *Souroubea guianensis* (Marcgraviaceae). In W Valle del Cauca, in Colombia, recorded as taking at least 32 species of fruit, which comprised 80% of 758 foraging observations; various species of melastome comprised 55% of all fruit taken, and one genus, *Miconia*, accounted for 88% of all melastome fruits consumed; *Cecropia* accounted for additional 21% of fruit eaten. Occurs in pairs and in groups of various sizes, occasionally of up to 15 individuals or even more, that associate with mixed-species flocks; often in mixed flocks with *T. arthus* and *T. florida*. In W Valle del Cauca, foraged mainly in crowns of shrubs or trees (78% of 523 observations), with median foraging height 8·6 m (706 observations), and rarely below 3 m. Took fruit usually from upright perched position, also readily hung head downwards from petioles, leaves or catkins to reach *Cecropia* catkins and similar; rarely clung to larger fruits or berries to peck out pieces, or snatched berries in flight, or ate flower buds. Insect-seeking done predominantly on sides or undersides of thin mossy branches (1·3 cm or less in diameter); hops quickly, or pauses to lean, head down, to check first one side and then the other; less often hung or clung to moss clumps, ferns, vines or stems to obtain prey, or probed into moss or bromeliads, or hanging dead leaves. Has been reported as descending low to forage opportunistically at swarm of army ants (*Labidus praedator*) in Colombian Andes; a group of ten of these tanagers was once observed at a highland army-ant swarm in Colombia. Behaviour in general similar to that of *T. arthus* and *T. florida*.
Breeding. Season Feb–Sept in Costa Rica breed (all records above c. 750 m), and breeding recorded in Feb in Panama and in Feb, Apr and Oct in Colombia; sometimes two broods attempted. Following details from study of 52 nests in Costa Rica. Nest material gathered by both sexes (male's contribution variable), female may build nest alone or male may help, most construction work done in morning hours, work completed in 3–6 days; nest a bulky structure of moss (especially base), leaves, ferns, spider web and plant filaments, hidden 1–11 m (rarely to 13 m) above ground on mossy branch of isolated tree in clearing adjacent to forest or tree in bushy pasture or tree in garden around house, some nests no doubt located inside forest. Clutch 2 eggs, dull white or greyish, thickly marked with brown, especially at large end; incubation by female alone, period c. 13–14 days; chicks fed by both adults, nestling period c. 15 days. Success: c. 54% of nests in Costa Rica produced at least one fledgling.
Movements. Seasonal elevational movements downslope almost to sea-level occur on both slopes during rainiest months in Costa Rica. Little or no such movement observed on Pacific slope in Anchicayá Valley, in Colombia.
Status and Conservation. Not globally threatened. Fairly common to common throughout range. Sight record of this species in NE Peru (E Tumbes) may involve a vagrant individual or, perhaps, be indicative of a small resident population. Occurs in a number of protected areas, including Braulio Carrillo, Tapantí and Chirripó/La Amistad National Parks (Costa Rica), La Amistad, Volcán Barú, Santa Fé and Darién National Parks (Panama), and Los Katíos, Tatamá, Farallones de Cali and Cerro Munchique National Parks and Tambito and El Pangan Nature Reserves (Colombia), also in Cotocachi-Cayapas Ecological Reserve (Ecuador). Deforestation resulting from mining, human settlement and various agricultural activities has reduced and fragmented this species' range everywhere, and these activities are increasing dramatically in parts of its range, especially in Colombia.

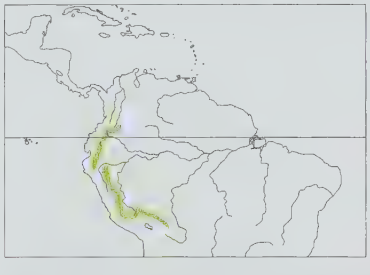
120. Saffron-crowned Tanager

Tangara xanthocephala

French: Calliste à tête dorée **German**: Gelbkopftangare **Spanish**: Tangara Coronigualda

Taxonomy. *C.*[*allospiza*] *xanthocephala* Tschudi, 1844, Vítoc [Valley], Junín, Peru.
Genetic data indicate that this species is part of a monophyletic group that includes also *T. johannae*, *T. schrankii*, *T. florida*, *T. arthus*, *T. icterocephala*, *T. chrysotis* and *T. parzudakii*. Three subspecies recognized.
Subspecies and Distribution.
T. x. venusta (P. L. Sclater, 1855) – W Venezuela (both slopes of Sierra de Perijá; Andes from S Lara S to S Táchira), Colombia (both slopes of W & C Andes, locally both slopes of E Andes, and Macarena Mts) and Ecuador (both slopes) S to N & C Peru (E slope of E Andes from Cajamarca S to N Pasco).
T. x. xanthocephala (Tschudi, 1844) – E slope of Andes in C Peru (Chanchamayo region).
T. x. lamprotis (P. L. Sclater, 1851) – E slope in SE Peru (Ayacucho and Cuzco) S to Bolivia (to W Santa Cruz).



Descriptive notes. 13 cm; 15–23·6 g. Colourful Andean tanager with blue-green body and yellow to orange on head. Male nominate race has small black mask consisting of narrow black line over bill and black lores, orbital ring and throat; rest of head bright saffron-yellow, black nuchal collar extending narrowly across side of neck to meet black of throat; upperparts mainly opalescent blue to turquoise-green (depending on light), mantle and back streaked with black (black feathers broadly edged blue-green); tail black, outer feathers edged turquoise-blue; upperwing-coverts black, narrowly edged bright turquoise-blue, primaries jet-black, edged dull bluish-green, inner secondaries and tertials black, narrowly edged pale blue; foreneck to upper breast and sides and flanks shining opalescent blue to greenish-blue, centre of mid-breast to belly and undertail-coverts buff to cinnamon-buff; iris dark brown; bill black; legs dark horn-grey. Female is similar to male, but duller, e.g. buff of underparts lighter and less rich. Juvenile is very dull and with little of adult pattern evident, although may have paler yellowish-brown head; immature also very dull, but with slightly contrasting dingy yellowish head, black mask faint or lacking, back dull greenish-blue with dusky scales and streaks, rump mixed dull opalescent green and brown, wing and wing-coverts dusky with hint of greenish edging, throat and underparts mainly dingy greyish to greenish-buff, becoming much more buff to cinnamon on belly and undertail-coverts. Race *lamprotis* differs from nominate in having crown contrastingly deep orange (not yellow), cheek deeper golden-yellow, back more extensively black (almost solidly black on some) and with streaking more opalescent green, and rump opalescent green; *venusta* differs from previous in having crown bright yellow (not orange), and back streaked black and opalescent blue (not so greenish). Voice. Contact note during foraging a high "tsit", when excited a rapid stream of "tsit" notes. Possible song a short series of high squeaky or wheezy notes.
Habitat. Humid and wet mossy forest, along forest borders and in middle-aged and older second growth; sparingly in scattered trees in clearing near forest. At 1000–2600 m, generally most numerous above c. 1400 m; once to 3150 m in Colombia.
Food and Feeding. Mostly small fruits, including *Miconia* species, *Cecropia* and *Morus*, also some arthropods; regularly seen to take nectar from *Inga* flowers in Urubamba Valley (Cuzco), in Peru. Of 15 stomachs examined, 13 contained only vegetable matter and two contained both vegetable and animal matter, including fruit pulp, berries, seeds and insects. Most often seen in groups of 3–10 individuals, sometimes more, with mixed-species flocks containing other tanagers and New World warblers (Parulidae). Forages from eye level to canopy. Takes fruit usually while perched upright and without acrobatics. Searches for insects by peering with head down first along one side of branch and then along other; unlike others of genus that use this method (e.g. *T. arthus* and *T. icterocephalus*), forages on average more on slender and bare to partly mossy branches and twigs, somewhat less on larger mossier branches.
Breeding. Nest in Nov in Peru; birds in breeding condition in Mar–Jul in Colombia. Peru nest was 12 m up in clump of moss hanging from beneath branch and c. 0·7 m from trunk. No other information.
Movements. Resident. Some minor seasonal elevational movements possible.
Status and Conservation. Not globally threatened. Fairly common to common on E slope of Andes; rare to uncommon on W slope in Ecuador. Occurs in numerous protected areas, including Guaramacal and Sierra Nevada National Parks (Venezuela), La Orquídeas, Farallones de Cali, Cerro Munchique and Chingaza National Parks and Río Blanco de Manizales, Tambito and El Pangan Nature Reserves (Colombia), Sangay and Podocarpus National Parks and Cayambe-Coca Ecological Reserve (Ecuador), Manu National Park (Peru) and Madidi National Park (Bolivia). Although the species' range, especially in N, is now fragmented and reduced by deforestation, considerable intact habitat exists outside protected areas and at least parts of this thought not likely to be at risk in the near future.
Bibliography. Burns & Naoki (2004), Clements & Shany (2001), Donegan & Dávalos (1999), Donegan *et al.* (2007), Dunning (1982), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Mee *et al.* (2002), Meyer de Schauensee (1964, 1966, 1970a), Miller (1963), Naoki (2003c), Remsen *et al.* (1987), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schulenberg *et al.* (2007), Sedano & Burns (2010), Terborgh & Weske (1975), Walker (2001), Zimmer (1943b).

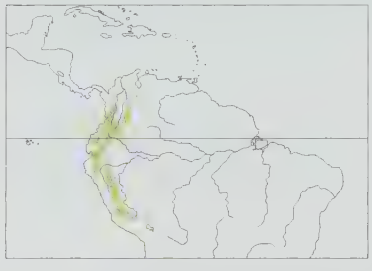
121. Golden-eared Tanager

Tangara chrysotis

French: Calliste à oreilles d'or **German**: Goldohrtangare **Spanish**: Tangara Orejidorada

Taxonomy. *Calliste chrysotis* du Bus de Gisignies, 1846, Peru.
Genetic data indicate that this species is part of a monophyletic group that includes also *T. johannae*, *T. schrankii*, *T. florida*, *T. arthus*, *T. icterocephala*, *T. xanthocephala* and *T. parzudakii*. Monotypic.
Distribution. S Colombia (at head of Magdalena Valley in Huila; E slope of E Andes from Caquetá) S on E slope through Ecuador, E Peru and N Bolivia (S to Yungas of Cochabamba).

Descriptive notes. 14 cm; 23–25·5 g. Distinctively marked, mostly lime-green tanager with black crown, golden to yellow cheeks and rufous lower underparts. Male has centre of crown to nape, narrow line over bill, lores, tiny area around eye and chin black, narrow black moustachial line ending in small streaked area on side of neck; forehead and supercilium shining straw-yellow, patch from below eye to ear-coverts coppery gold (ear-coverts can be spread outwards, looking like small ears); mantle and back black, streaked lime-green, lower back to uppertail-coverts pale lime-green; upperwing-coverts, primary coverts and flight-feathers black, heavily edged bluish-green; throat and underparts shining lime-green, centre of lower breast, centre of belly and undertail-coverts contrastingly rich cinnamon-rufous; iris dark brown; bill black; legs dark grey. Female is similar to male, but duller, and generally with cheek and ear-coverts straw-yellow (not coppery gold). Juvenile is much duller above and below, and without sharply contrasting black-and-green pattern. Voice. Call "tsuck", somewhat lower-pitched than calls of congeners; also a strong, doubled "tsuck-seet", varied to "chuk-eet", and variety of thin high notes. Captive males sing a hissing, piping song or series of high rattling notes while raising ear-tufts.
Habitat. Humid and wet pre-montane and montane forest, forest borders, and older second-growth woodland. Occurs in narrow elevational band on E slope of Andes: c. 1100–2400 m in Colombia, 1100–1700 (once down to 850 m) in Ecuador, 1100–2300 in Peru, and 1150–1750 m in Bolivia; old (presumed 19th-century) Bolivian records ranging from 760 m to 2100 m.
Food and Feeding. Fruits, some arthropods. One stomach contained small worms (Oligochaeta) and plant material. Eats many small fruits, especially melastome (*Miconia*) berries. Typically singly and in pairs, much less infrequently groups of three or four individuals, and generally with large mixed-species flocks containing other members of genus. Forages mostly from middle heights to canopy of trees; in Bolivia c. 10–30 m above ground, median distance to top of canopy was c. 1·5 m. Active, fast-moving and apt to spend only brief periods of time in a tree before flying ahead to another site nearby. Readily visits fruiting trees, especially when congeners present, but often remains for only a few moments. In Peru and Bolivia works rapidly along bare or mossy branches of 2·5–7·6 cm in diameter, gleaning insects partly by hopping and peering with head down on alternate sides of branches in stereotyped manner typical of many others of its genus; also checks dead leaves, and gleans insects from outer leaves. Erectile ear-tufts used in displays of aggression (possibly also in courtship), when bird may posture motionless with ear-tufts erected and head raised for up to several minutes.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon. Generally less numerous than other members of genus with which it occurs. Found in a few protected areas, including Cayambe-Coca Ecological Reserve and Sangay and Podocarpus National Parks (Ecuador), Tingo Maria and Manu



National Parks (Peru) and Madidi National Park (Bolivia). Confined to a narrow band of humid forest on E Andean slope where considerable intact forest still remains, but this is a region of increasing human activity and settlement, and deforestation may eventually put this species at risk.
Bibliography. Burns & Naoki (2004), Hilty & Brown (1986), Ingels (1974b), Isler & Isler (1999), Lysinger *et al.* (2005), Norgaard-Olesen (1973), Parker & Parker (1982), Remsen (1984), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010), Weske (1972), Zimmer (1943b).

122. **Flame-faced Tanager**

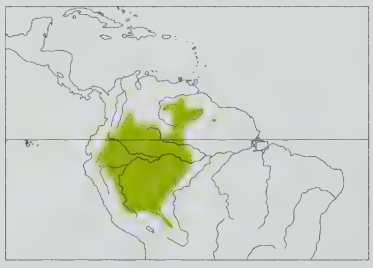
Tangara parzudakii

French: Calliste à face rouge **German**: Rotstirntangare **Spanish**: Tangara Carafuego
Other common names: Yellow-faced Tanager (*lunigera*)

Taxonomy. *Tanagra Parzudakii* Lafresnaye, 1843, environs of Santa Fé de Bogotá, Colombia.
Genetic data indicate that this species is part of a monophyletic group that includes also *T. johannae*, *T. schrankii*, *T. florida*, *T. arthus*, *T. icterocephala*, *T. xanthocephala* and *T. chrysotis*. Three subspecies recognized.
Subspecies and Distribution.
T. p. lunigera (P. L. Sclater, 1851) – Pacific slope of W Andes from Colombia (S from Risaralda) S to W slope in Ecuador (S to El Oro).
T. p. parzudakii (Lafresnaye, 1843) – SW Venezuela (Andes of SE Táchira); E Andes of Colombia (W slope from Santander to Cundinamarca and head of Magdalena Valley in Huila; E slope probably throughout, but recorded only Meta, Caquetá, Putumayo and Nariño) and E slope in Ecuador.
T. p. urubambae J. T. Zimmer, 1943 – E slope of Andes in Peru (S to Cuzco and Ayacucho).

Descriptive notes. 14–15 cm (nominate), c. 13–14 cm (*lunigera*); 25–31 g. Boldly coloured tanager with flame-red to orange on face. Nominate race has lowermost forehead, lores, ocular ring, chin, throat and broad bar extending across side of neck black (sometimes a narrow black line behind eye extending to meet top of neck band); cheek and malar region deep flame-red, upper forehead and forecrown deep flame-red, becoming bright silky yellow on hindcrown and nape; mantle and upper back black, lower back and rump opalescent to golden-straw, often with bluish tinge, and feathers of uppertail-coverts usually showing more bluish; tail black; lesser and median upperwing-coverts shining opalescent bluish to greenish opalescent, greater coverts jet-black, broadly edged shining pale blue (varying with light to slightly greenish); flight-feathers jet-black, secondaries and tertials narrowly and inconspicuously edged bluish; underparts shining opalescent silvery green mixed with buff (colour highly variable depending upon light), centre of belly pale cinnamon-buff, becoming darker on flanks and undertail-coverts; iris dark brown; bill black; legs dark grey. Sexes similar. Immature has red areas of head replaced by dull yellow, throat dingy pale buffy grey, other black areas of plumage dull dusky, black of lores and ocular ring obscure, and plumage overall much duller and lacking shining aspect, below dull pale greyish-buff (sometimes hint of greenish), lower underparts dull buff, turning cinnamon on undertail-coverts. Race *lunigera* is slightly smaller than nominate, has forecrown and cheek orange-red (not red) and malar area yellow, shoulder and tips of median and greater wing-coverts more silvery green (less blue), lower back to uppertail-coverts with stronger greenish-opalescent tinge, chest to mid-breast brighter silvery opalescent green, and central lower underparts darker cinnamon-buff; *urubambae* is much like nominate, differing in shorter bill, slightly darker and duller red forehead, top of head on average slightly lighter yellow, underparts with dusky subterminal area of feathers more pronounced, belly paler tawny and with hint of streaking. Voice. Calls include a notably high-pitched, slightly buzzy "seeet" note; also a sharp, forceful, smacking "chit!" or "tsuk!", and a series of "ti" notes, especially in flight. Song not certainly described, possibly a series of "chit" notes accelerating into twittering trill.
Habitat. Humid and wet montane forest, and adjacent older second growth. Less at forest borders than many congeners. At 1000–2600 m (once to 700 m on Pacific slope) in Colombia, 1100–2400 m (once to 700 m) in Ecuador, and 1500–2500 m in Peru; in all areas most numerous at c. 1800 m.
Food and Feeding. Fruits, also arthropods. Eight stomachs contained vegetable matter, including fruit and seeds. Like its congeners, seems to eat variety of small fruits and berries, especially of *Miconia*, larger-sized melastome fruits, and *Cecropia* catkins. Most often seen singly or in pairs, much less often in groups of 3–7 individuals, and usually with mixed-species flocks containing other members of genus. Active bouts of foraging regularly interrupted by periods of quiet, when it perches in canopy for up to 10–15 minutes. Most often searches mossy limbs, where it employs diagonal-lean or head-down method, peering first on one side of branch and then on other, as do many others of genus. Also regularly hangs head downwards on sides of mossy branches, peers beneath mossy limbs, often in rather methodical and deliberate manner, and probes and pecks at moss; rarely forages in outer foliage.
Breeding. Nest-building in Feb and nest with chick found in Jun in NW Ecuador; nest-building, courtship feeding and birds in breeding condition in Feb–Jun in Colombia. Following details from two nests at 1800 m, in Inti Llacta Reserve, NW Ecuador. One nest being built by female, accompanied for most of time by male, construction work continued for six days; placed 20 m up in isolated *Ceroxylon* palm; incubation by female, seen to be fed once by male; nest attempt apparently failed. Second nest, made from leaf fragments, moss, tiny twigs, pieces of orchid stems, bits of *Chusquea* bamboo leaves and similar, placed 3 m up in *Cinchona* shrub (close to failed Feb nest in palm); contained one nestling, also one egg, white with red-brown spots.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Distribution in Colombian E Andes not fully known: probably found throughout, at least formerly, on W slope; on E slope recorded only from Meta, Caquetá, Putumayo and Nariño but, again, likely to be present throughout. Occurs in a few protected areas, including Las Orquídeas, Tatamá, Farallones de Cali and Cueva de los Guácharos National Parks and Tambito Nature Reserve (Colombia), Cayambe-Coca Ecological Reserve and Sangay and Podocarpus National Parks (Ecuador) and Tingo Maria National Park (Peru). Confined to a narrow band of humid forest on E Andean slope, where considerable unprotected intact forest still remains; increasing human settlement and deforestation in this area, however, may eventually put this species at risk.
Bibliography. Álvarez-Rebolledo *et al.* (2007), Arcos-Torres & Solano-Ugalde (2007), Athanas (2010a), Burns & Naoki (2004), Clements & Shany (2001), Donegan & Dávalos (1999), Donegan *et al.* (2007), Fjeldså & Krabbe (1990), Hesse (1980b), Hilty (2009a), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1964, 1966, 1970a), Moore *et al.* (1999), Naoki (2007), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schulenberg *et al.* (2007), Sedano & Burns (2010), Walker (2001), Zimmer (1943b).

PLATE 13 ➤



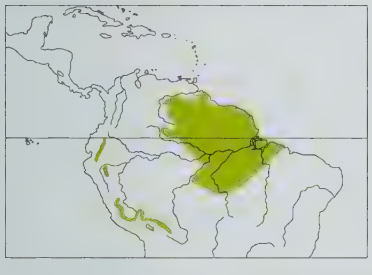
123. **Yellow-bellied Tanager**

Tangara xanthogastra

French: Calliste à ventre jaune **German**: Gelbbauchtangare **Spanish**: Tangara Ventriamarilla

Taxonomy. *Calliste xanthogastra* P. L. Sclater, 1851, Río Negro, Peru.
Genetic data indicate that this species and *T. punctata*, *T. guttata*, *T. varia* and *T. rufigula* form a species group. Highland race *phelpsi* differs in numerous ways from nominate, and may merit separate species status. Two subspecies recognized.
Subspecies and Distribution.
T. x. xanthogastra (P. L. Sclater, 1851) – E Colombia (from Meta and Vaupés) E to S Venezuela (S Amazonas and SW Bolívar), S to E Ecuador, E Peru, W Brazil (E to R Negro, middle R Juruá and upper R Purús), and N Bolivia (S to Cochabamba).
T. x. phelpsi J. T. Zimmer, 1943 – S Venezuela in N Amazonas and N & E Bolívar (from lower R Caura E to Uei-tepui, on Brazilian border); also E Guyana.
Descriptive notes. 11 cm; 13–18 g. Small, green, heavily spotted tanager with bright yellow along central abdomen; bill rather thin. Nominate race has lores black, ocular ring bright green, rest of

head and neck mainly bright emerald-green, spotted black (feathers black with rounded green edges); upperparts black, rounded feather edges broadly pale greenish-blue (imparting spotted appearance), rump greenish, vaguely mottled with black; rectrices dusky with bright bluish-green edges; upperwing-coverts black, broadly edged and tipped greenish-blue, primary coverts and flight-feathers black, edged greenish-blue, tertials more broadly and roundly edged greenish-blue; below mainly green, speckled with black and mixed yellow, and becoming mostly bright unspotted yellow on centre of lower breast and belly; sides and flanks mainly green, mixed yellow; iris dark brown; bill black; legs dark grey. Sexes similar. Juvenile undescribed. Race *phelpsi* is similar to nominate, but has slightly longer wing and tail, heavier bill, more yellowish-green head, duller flanks, and more yellow on underparts, including belly. VOICE. Weak "chit" and "seet" notes, much like those of many congeners.



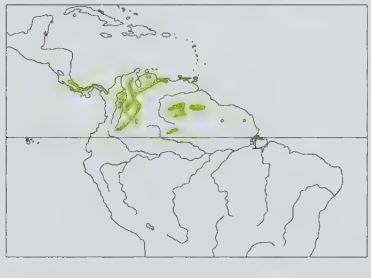
Song a series of descending, buzzy trills, "tic tic'Zzzzzzzzeeeer", shrill, fairly high-pitched and repeated at maximum rate of about one song every 2–3 seconds; possible song, in Peru, a high, buzzy "tik tik-tik dzheeweew".
Habitat. Primarily occurs in high canopy and emergent trees of humid *várzea* and *terra firme* forest; mainly found at elevations of 100–750 m. In contrast, highland race *phelpsi* inhabits humid and wet montane forest, forest borders, and stunted or disturbed melastome-dominated second-growth forest on both white sand and other soil types, in tepui highlands at elevations of c. 1000–1800 m.
Food and Feeding. Diet includes small fruits and insects. Recorded fruits are *Miconia* species and other melastome berries, *Cecropia* catkins, and mistletoe berries (Loranthaceae). Of 13 stomachs of nominate race examined, nine contained only vegetable matter and four only animal matter; contents included fruit and caterpillars (one of latter measuring 4 cm). Notably social, usually seen in small groups that forage with mixed-species flocks containing other members of its genus; regularly visits fruiting trees and shrubs with other species. Early in morning, lowland birds often perch in open atop high emergent trees, regularly gathering with other members of genus and *Dacnis* and *Cyanerpes* species before setting off to forage. Nominate race in lowlands forages mainly high in canopy and emergent treetops, and rarely seen lower; those in Andean foothills, however, behave more like tepuis race (*phelpsi*), foraging from middle heights to canopy and regularly coming down to eye level along forest borders to visit fruiting shrubs. Insect-hunting somewhat generalized, includes some lean-down branch-searching (like that of e.g. *T. arthus*), and acrobatic searching of foliage in outer perimeter of trees (much like that of *T. guttata*).
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon, and at rather low density across lowlands; race *phelpsi* perhaps locally more numerous in tepui highlands. Occurs in numerous protected areas. Highland *phelpsi* found in Canaima, Jaua-Sarisariñama and Serranía de la Neblina National Parks, in Venezuela, and probably also Pico da Neblina National Park, in adjacent N Brazil; lowland nominate race occurs in almost all national parks in Amazonian lowlands of SE Colombia, E Ecuador and E Peru S to Madidi National Park, in Bolivia, as well as in Serra do Divisor National Park (and probably others), in Brazil. In addition, extensive unprotected habitat exists within this species' range, and it appears unlikely to be faced with any serious threats even in the long term.
Bibliography. Burns & Naoki (2004), Dunning (1982), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Moore *et al.* (2009), O'Neill (1974), Phelps & Phelps (1963), Remsen & Traylor (1983), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010), Snethlage (1914), Souza (2002), Zimmer (1943b).

124. Spotted Tanager

Tangara punctata

French: Calliste syacou **German**: Drosseltangare **Spanish**: Tangara Puntosa

Taxonomy. *Tanagra punctata* Linnaeus, 1766, Suriname.
Genetic data indicate that this species and *T. xanthogastra*, *T. guttata*, *T. varia* and *T. rufigula* form a species group. Despite significant geographical separation, as well as differences in habitat elevation, the possibility that western and eastern populations may represent two distinct species has not yet been investigated in detail. Five subspecies currently recognized.
Subspecies and Distribution.
T. p. zamorae Chapman, 1925 – E slope of Andes in Ecuador (Sucumbíos) and N Peru (Moyobamba).
T. p. perenensis Chapman, 1925 – E slope of Andes in C Peru (Junín, mainly in Chanchamayo area).
T. p. annectens J. T. Zimmer, 1943 – E slope in SE Peru (Inambari region).
T. p. punctulata (P. L. Sclater & Salvin, 1876) – E slope in N Bolivia (La Paz and Cochabamba).
T. p. punctata (Linnaeus, 1766) – S Venezuela (S of R Orinoco), the Guianas, and N Brazil (R Negro E to Amapá and, S of Amazon, in Pará).



Descriptive notes. 11–12 cm; 13–17 g. Small, mostly green tanager with dark-spotted appearance. Nominate race on entire front half of body, above and below, has dark feathers broadly fringed yellowish-green, palest on face to lower breast, crown to back edged green, crown more strongly tinged greenish-blue; rump and uppertail-coverts unspotted green; tail blackish, edged green; upperwing and its coverts blackish, feathers edged blue-green to green, usually greenest on lesser coverts, tertials broadly edged greenish; below spotted breast, the sides, flanks and undertail-coverts are yellowish-green, centre of belly white; iris brown; bill black; legs slate-coloured. Female is similar to male, but black spotting above and below somewhat duller. Immature is considerably duller than adult, with spotting dull brownish-grey (not black) and not well defined, and lower underparts dull whitish with traces of darker feather tips. Races differ mainly in darkness of plumage coloration: *zamorae* is slightly larger than nominate, with wing-coverts and flight-feathers edged green; *perenensis* has the least spotted underparts of any race, and lower underparts more broadly pure white, female spots especially dull; *punctulata* differs from previous in stronger yellow tinge on mantle and wing-coverts, paler rump and flanks, and even more spotting below; *annectens* is intermediate between preceding two races, being more heavily spotted above and below than *perenensis* but less sharply marked than *punctulata* and, compared with latter, has less white above lores, darker rump and flanks, less yellowish on margins of mantle feathers and upperwing-coverts, and less extensive spotting below. Voice. Call a sharp "tsuu" and extremely high "chip" or "tsick", usually in rapidly repeated staccato series, sometimes accelerating into a trill, and sometimes diminishing at end. Some of these series may constitute a song.
Habitat. Mainly humid and wet pre-montane forest, forest borders and second-growth woodland in Andes, often where forest fairly mossy; c. 500–2000 m. Lowland nominate race in humid forest, forest borders, and scrubbier savanna forest, second growth and shady plantations; from lowlands to 1600 m.
Food and Feeding. Diet consists of fruits and arthropods. Of five stomachs examined, four contained only vegetable matter and one only animal matter; contents included fruit pulp, seeds, berries, and a snout beetle (Curculionidae). Most often seen in pairs or in groups of 3–4, although occasionally up to eight individuals. In Andes generally found with mixed-species flocks, as is also the case in E Venezuelan lowlands; around Manaus, in Brazil, however, recorded only sporadically with mixed flocks; in all parts of range readily joins groups of small birds at fruiting trees. Forages high, mostly 15–50 m up, occasionally lower in small trees or tall shrubs at forest edge. Forages for insects mainly in outer foliage, where it hops and peers actively in outermost leaves, sometimes walking or standing atop foliage. May take prey about equally from top and bottom surfaces of leaves.
Breeding. No information.
Movements. Probably resident. No movements verified but, if they occur, likely confined to local shifts in response to fruit abundance.
Status and Conservation. Not globally threatened. Uncommon in Guianan and E Amazonian lowlands; fairly common to locally common in Andes. The four Andean races occur in several large protected areas, among them Cayambe-Coca Ecological Reserve and Sangay and Podocarpus National Parks (Ecuador), Manu National Park (Peru) and Madidi National Park (Bolivia). Single E race (nominate) can be found in Canaima National Park (Venezuela), Kaieteur National Park (Guyana), Brownsberg Nature Park and the Central Suriname Nature Reserve (Suriname), and Montanhas do Tumucumaque National Park (Brazil), among others. This species' Andean range includes considerable intact but unprotected forest that is subject to deforestation from various human activities, but is probably secure in the short term. E population faces few, if any, current or imminent threats.

125. Speckled Tanager

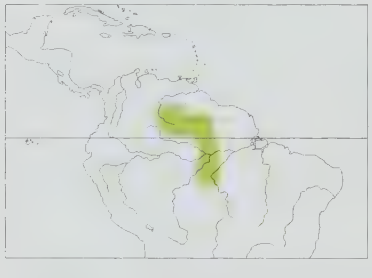
Tangara guttata

French: Calliste tiqueté **German**: Fleckentangare **Spanish**: Tangara Pintoja

Taxonomy. *C.*[*allispiza*] *guttata* Cabanis, 1851, Cerro Roraima, Bolívar, Venezuela.
Genetic data indicate that this species and *T. xanthogastra*, *T. punctata*, *T. varia* and *T. rufigula* form a species group. Nominate race isolated; the possibility that the other races might merit treatment as a separate species may be worth investigating; taxonomic status of *chrysophrys* may likewise deserve research. Six subspecies recognized.
Subspecies and Distribution.
T. g. eusticta Todd, 1912 – Costa Rica (from Alajuela and, on Pacific slope, from San José) E to Panama (Caribbean slope) and extreme W Colombia (Cerro Tacarcuna, in extreme NW Chocó).
T. g. tolimae Chapman, 1914 – E slope of C Andes of Colombia (S to Tolima).
T. g. bogotensis Hellmayr & Seilern, 1912 – Sierra de Perijá, Andes of Venezuela (from Lara S to Táchira), and adjacent E Andes of Colombia (W slope from Norte de Santander S to Cundinamarca, Macarena Mts, and to W Caquetá and E Cauca, possibly also Nariño; probably throughout E slope, but records sparse).
T. g. chrysophrys (P. L. Sclater, 1851) – N & S Venezuela (Sierra San Luis, in Falcón, and coastal cordilleras from Yaracuy E to Sucre and Monagas; also locally in mountains of Amazonas and Bolívar) and extreme NW Brazil (Sierra de Curupira).
T. g. trinitatis Todd, 1912 – N Trinidad.
T. g. guttata (Cabanis, 1851) – SE Venezuela (SE Bolívar E of R Caroní), adjacent extreme N Brazil (Cerro Uei-tepui), and locally in the Guianas.

Descriptive notes. 12 cm; 15–20·5 g. Small, mostly green tanager with yellow-tinged face and dense black spotting. Nominate race has lores black, forehead, eyebrow and orbital area bright yellowish; rest of head and upperparts mainly green, spotted and scaled with black (feathers with black centres and broad rounded greenish edges), rump and uppertail-coverts dull unspotted greenish or with indistinct blackish mottling; tail dusky green, edged green, brightest on margins and fading toward centre of each feather; upperwing-coverts black, broadly edged and tipped pale opalescent blue, primary coverts dusky, faintly edged greenish-blue, flight-feathers including tertials black, basal half of primaries edged green, secondaries edged bluish, tertials edged pale bluish and tipped greenish; throat, breast and sides white, spotted black (spots tiny on throat, becoming progressively larger on breast), centre of lower breast and belly unspotted white, flanks and undertail-coverts yellow-green; bend of wing and underwing-coverts white; iris dark brown; bill black; legs dark grey. Sexes similar. Juvenile is like adult, but back and breast less speckled and yellow superciliary obscure or lacking. Race *tolimae* has crown and side of head mainly yellowish-green (little yellow on head), lower breast, belly and undertail-coverts olive-yellow, flanks bright grass-green; *bogotensis* is similar to previous, but upperwing-coverts and secondaries more extensively edged blue and flanks duller green; *eusticta* has rump bright yellowish-green, and undertail-coverts yellowish with black spots; *trinitatis* has more extensive yellowish on forehead, eyebrow and facial area than all preceding races, and yellow colour relatively rich; *chrysophrys* is much like last, but forehead paler yellow and upperparts brighter yellow-green. Voice. More vocal than many congeners, often almost constantly uttering high-pitched "chit, chip" and "tsit" notes, often in fast stream when about to take flight, or in flight. Some notes clear, almost bell-like. No definite song yet described.
Habitat. Humid foothill forest and mountain forest, forest borders, second growth and adjacent shady tree-scattered clearings; also sometimes in disturbed vegetation around human dwellings. In some areas, such as Trinidad, appears to be confined to tall forest and old second growth. Re-

On following pages: 126. Dotted Tanager (*Tangara varia*); 127. Rufous-throated Tanager (*Tangara rufigula*); 128. Bay-headed Tanager (*Tangara gyrola*); 129. Rufous-winged Tanager (*Tangara lavinia*).



corded at 300–2000 m; in Costa Rica, mainly 400–1000 m on Caribbean side and 300–1400 m on Pacific side; c. 450–1350 m in Panama; mostly 700–1500 m in Andes.
Food and Feeding. Small and large fruits, also some arthropods. Of three stomachs examined, two contained only vegetable matter and one contained both vegetable and animal matter; contents included fruit and a beetle (Coleoptera). In Trinidad, recorded as eating 14 species of fruit, which comprised 74% of 96 foraging records; *Miconia* berries accounted for 53% of all fruit taken; other common species exploited included species of Euphorbiaceae and Ulmaceae (36% of fruit taken). In Costa Rica six species of arillate fruit taken, especially *Souroubea guianensis* (Marcgraviaceae) and *Dipterodendron elegans* (Sapindaceae). Also readily comes to feeding trays, where it eats a variety of cultivated fruits. Notably social, outside breeding period almost always seen in lively little family parties or groups of up to eight or so individuals, and often with mixed-species canopy flocks, especially those containing other members of its genus; some evidence suggests that amount of time spent with mixed-species flocks varies geographically; regularly with other small frugivores at fruiting trees. Forages mostly in canopy, but will descend low to fruiting shrubs; in Trinidad, rarely below 3·5 m above ground. Small berries swallowed whole; pecks pieces from large fruits. Seeks insects in high foliage near tips of branches; often rather acrobatic as it scrambles out through foliage, peers up, leans out or down, hang downwards, or clings beneath leaves to check leaf surfaces, all of this behaviour typical of genus.
Breeding. Recorded in Apr–Jun in Costa Rica; birds in breeding condition in May–Jun in NE Colombia. In Costa Rica, helpers observed to attend nests. Nest built by both sexes, a tight open cup of leaves, leaf fragments and rootlets; in Costa Rica five nests were 3–8 m up in foliage, four in isolated trees. Clutch 2 eggs, mottled brown, especially at larger end; incubation by female, occasionally fed by male, period 13 days; nestling period c. 15 days; family-members may remain together for up to a year.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in various protected areas, including Braulio Carrillo, Tapantí and Chirripó/La Amistad National Parks (Costa Rica), La Amistad, Santa Fé and Darién National Parks (Panama), Los Katíos National Park and Reinita Cielo Azul, Arrierito Antioqueña, Bavaria and Río Blanco de Manizales Reserves (Colombia), and Yacambú, Henri Pittier, Paria and Canaima National Parks (Venezuela). The ability of this species to use older second growth, coffee plantations and other disturbed sites provides an important buffer against habitat loss, although it also will be vulnerable to extensive deforestation and fragmentation of habitat in longer term.

126. **Dotted Tanager**

Tangara varia

French: Calliste tacheté **German**: Tüpfeltangare **Spanish**: Tangara Manchada

Taxonomy. *Tanagra varia* Statius Müller, 1776, Cayenne, French Guiana.
Genetic data indicate that this species and *T. xanthogastra*, *T. punctata*, *T. guttata* and *T. rufigula* form a species group. Monotypic.
Distribution. S Venezuela (E & S Amazonas E of R Orinoco, and S Bolívar), SW Guyana and N Brazil (N of R Amazon, from R Negro E to C Pará; S of R Amazon, from lower and middle R Tapajós E to E of R Xingu); old records from SW Suriname and E French Guiana; recent records NE Peru (local) and E Colombia (sight record near Inírida, in Guainía).

Descriptive notes. 11 cm; one bird 10 g. Small tanager, essentially uniformly green, and can easily be confused with immatures of several congeners. Male is mostly bright green above and below; lores black; upperwing-coverts edged dull greenish-blue, outer primaries dusky with minimal edging, inner primaries, secondaries and tail are dusky, edged dull greenish-blue, tertials mostly greenish-blue with dusky inner webs; throat, side of head and chest, sometimes also forecrown, weakly dotted with black, or with black feather bases showing through here and there (inconspicuous at distance); iris dark brown; bill black; legs dark grey. Female is similar to male, but lores green (not black), few or no black dots on foreparts, and throat and underparts slightly paler, more yellowish-green; wing-coverts and flight-feathers dusky, narrowly edged green (not blue). Juvenile undescribed. Voice. Song, in Peru, a high, hissing series of descending, melancholy notes, "tsip... tsee-tseee-tsee-tsee-tsee". Call a high "tsip".
Habitat. Humid forest and forest edge, second growth, trees in clearings adjacent to forest, and shady plantations; lowlands to c. 300 m.
Food and Feeding. Poorly known. Diet insects and fruit. Singles and pairs reported as regularly associated with mixed-species canopy flocks. Forages from middle levels to tree crown, 15–50 m above ground; searches small branches and foliage for food items.
Breeding. No information.
Movements. Presumably resident.
Status and Conservation. Not globally threatened. Rare. Poorly known, and perhaps often overlooked because of great height at which it normally occurs in forest. Recently recorded at one locality in E Colombia (Guainía), but probably more widespread in that region. Status in Suriname and French Guiana uncertain; scattered 19th-century records from both countries, but no known recent records. Found in a few parks, among them Jaua-Sarisariñama National Park and possibly Canaima National Park, in Venezuela; may occur also in Montanhas do Tumucumaque National Park, in Brazil. Although local and thinly spread across Guianan and NE Amazonian region, this species has a range encompassing vast amounts of unprotected but intact forest that is unlikely to be facing any serious threats in the immediate future.
Bibliography. Braun *et al.* (2000), Burns & Naoki (2004), Haverschmidt & Mees (1994), Hellmayr (1936), Hilty (2003), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Moore *et al.* (2009), Oren & Parker (1997), Phelps & Phelps (1963), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sick (1985, 1993), Souza (2002), Tostain *et al.* (1992), Willis (1977).

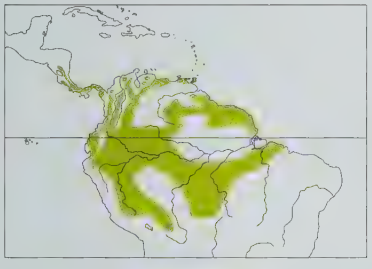
127. **Rufous-throated Tanager**

Tangara rufigula

French: Calliste à gorge rousse **German**: Rostkehltangare **Spanish**: Tangara Golirrufa

Taxonomy. *T.*[*anagrella*] *Rufigula* Bonaparte, 1851, Calacali, 12 miles [c. 20 km] north of Quito, Ecuador.
Genetic data indicate that this species and *T. xanthogastra*, *T. punctata*, *T. guttata* and *T. varia* form a species group. Monotypic.
Distribution. Pacific slope of Colombia (from below Cerro Tatamá, in Risaralda) S to W Ecuador (locally S to El Oro).

Descriptive notes. 12 cm; mean 19·1 g. Small, modestly patterned tanager with mostly black head and spotted underparts. Crown to nape and side of head to below eye are dusky black; lower nape and mantle to upper back black, heavily scaled greenish-buff to tawny, lower back and rump mostly unspotted glistening opalescent green to pale buff, with some black mottling; upperwing-coverts black, heavily edged and tipped pale blue-green to buff, primary coverts faintly edged bluish-green, basal half of outer 3–4 flight-feathers narrowly edged opalescent bluish-green, entire length of rest of inner primaries, secondaries and tertials narrowly edged pale bluish-green; chin and throat contrastingly dull rufous, wash of rufous spreading slightly onto chest; otherwise, chest, breast, sides and flanks opalescent green (often looking whitish), spotted and scaled black (centres of feathers black, rounded tips edged opalescent green-ish), centre of belly and undertail-coverts pale salmon-buff to whitish; iris dark brown; bill black, base of lower mandible greyish-horn; legs black. Sexes alike. Immature is duller than adult, but soon acquires some spotting and scaling. Voice. Relatively noisy and vocal for its genus, often uttering excited bursts of ticking and twittering notes, "tic-ti-ti-ti-ti-ti-ti-ti...", especially as pair flies back and forth across small clearing. Bursts of ticking notes may constitute a song.
Habitat. Humid to very wet pre-montane forest borders (mossy forest), and trees in small forest clearings; most numerous in broken or irregular forest on steep slopes, and usually not found in forest interior. At 400–2100 m.
Food and Feeding. Fruits and arthropods. Animal prey items identified include caterpillars, other larvae, and flying termites (Isoptera). In W Valle del Cauca, in Colombia, fruit comprised 73% of all foraging records, at least 24 species of fruit recorded in diet, and two-thirds of all fruits taken were *Miconia* berries, eaten green and ripe; *Cecropia* catkins comprised an additional 7% of fruit taken; flower parts and flower buds comprised 4% of diet, buds of *Topobea brachyura* (Melastomataceae) representing 67% of all flowers eaten. Occurs in pairs and in family groups of three or four individuals, independently of mixed-species flocks as often as with them; eagerly joins feeding assemblages at fruiting trees such as *Miconia*. From 1100 observations of foraging in W Valle del Cauca, median foraging height was c. 9 m, rarely (5% of records) less than 3 m; fruit taken, on average, at lower heights (8·5 m) than were insects (13·7 m). Takes fruit normally from a perched position, somewhat less often while hanging downwards; fruit items typically mashed and swallowed whole. Most insect-hunting was on surfaces of leaves in perimeter of canopy, where the species commonly employed acrobatic movements, including stretching upwards or outwards, and hanging downwards; also stood or hopped on upper surfaces of large leaves, and frequently sallied short distances (26% of all insect-searching records) to air or hovered at leaf surfaces (10% of insect captures).
Breeding. All data from Colombia. Breeding activities recorded Aug–Jan, with nests found in Aug and Sept, single individuals and pairs carrying nest material and building in mid-Oct and late Jan, and pair feeding young in mid-Dec. In upper R Anchicayá Valley (W slope of W Andes in Valle), two cup-nests made from moss found, one 10 m and the other 18 m above ground, one in epiphyte suspended (like hanging basket) by vine beneath large limb; a pair and one helper, presumed offspring from earlier brood, attended the higher nest, which later failed. No other information.
Movements. Resident. No movement recorded during 16-month observation of colour-ringed birds in Anchicayá Valley (1050 m), in Colombia.
Status and Conservation. Not globally threatened. Fairly common to locally common. Occurs in a few protected areas, notably Tatamá, Farallones de Cali and Cerro Munchique National Parks and Tambito and probably El Pangan Nature Reserves (Colombia), and probably also in Cotacachi-Cayapas Ecological Reserve (Ecuador). This species is vulnerable to deforestation within its narrowly prescribed range, but in the short term is secure as considerable intact habitat remains at present.
Bibliography. Burns & Naoki (2004), Donegan & Dávalos (1999), Dunning (1982), Hilty (1997, 2009a), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Moore *et al.* (1999), Naoki (2007), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sedano & Burns (2010).



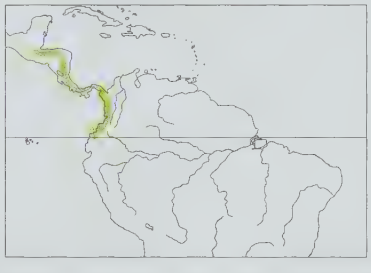
128. **Bay-headed Tanager**

Tangara gyrola

French: Calliste rouverdin **German**: Grüntangare **Spanish**: Tangara Cabecibaya
Other common names: Green Tanager; Bay-and-blue Tanager ("*albertinae* group"); Bay-and-green Tanager ("*viridissima* group")

Taxonomy. *Fringilla Gyrola* Linnaeus, 1758, Suriname.
Forms a superspecies with *T. lavinia*; replaced by latter in wet Chocó–Pacific lowlands. Races probably constitute more than a single species; morphological differences between some races as great as those between present species and *T. lavinia*. Races appear to form three plumage groups: "*albertinae* group" (including *bangsi*, *deleticia*, *nupera*, *catharinae* and *parva*), with blue underparts; "*viridissima* group" (including *toddi*), with green underparts; and monotypic "*gyrola* group", with mixed underparts; these have in the past been treated as three separate species. Name "*gyroloides*", dating to 1847, was in the past applied variously to birds of races *deleticia*, *albertinae* or *catherinae*; however, it is a replacement name for the preoccupied "*Aglaïa Peruviana*", which is itself unidentifiable due to contradictory features in the description. Nine subspecies recognized.
Subspecies and Distribution.
T. g. bangsi (Hellmayr, 1911) – E Nicaragua, Costa Rica and W Panama (E to Panamá).
T. g. deleticia (Bangs, 1908) – E Panama (Darién) and generally in W Colombia (E to W slope of E Andes, S to Patía Valley, in Nariño).

T. g. nupera Bangs, 1917 – SW Colombia (Nariño S of Patía Valley), W Ecuador and NW Peru (Tumbes).
T. g. toddi Bangs & T. E. Penard, 1921 – N Colombia (Sierra de Santa Marta, Sierra de Perijá, and E slope of E Andes in Norte de Santander and N Boyacá) and mountains of W & N Venezuela (E to Miranda).
T. g. viridissima (Lafresnaye, 1847) – mountains of NE Venezuela and Trinidad.
T. g. catharinae (Hellmayr, 1911) – E base of E Andes of Colombia (from Meta and Macarena Mts) S to E Ecuador, E Peru and Bolivia (S to Cochabamba and W Santa Cruz).
T. g. parva J. T. Zimmer, 1943 – S Venezuela (SW Amazonas), adjacent E Colombia, and mountains of adjacent N Brazil (upper R Negro).
T. g. gyrola (Linnaeus, 1758) – S Venezuela (from N Amazonas and NW Bolívar) E across the Guianas and extreme N Brazil (headwaters of R Uraricoera E to C & S Amapá).
T. g. albertinae (Pelzeln, 1877) – NE Peru (Loreto) and Brazil S of R Amazon (from R Purús E to NE Pará and S to N Mato Grosso).



Descriptive notes. 12 cm; 17·5–26·5 g. Small rufous-headed tanager, highly variable in plumage. Nominate race has entire head to hindcrown, chin and upper throat brownish-rufous, narrow golden-yellow nape band; upperparts entirely green, upper surface of tail green; lesser upperwing-coverts yellowish-green, median and greater coverts pale green, slightly tinged yellowish, flight-feathers dusky, basal half of outermost narrowly edged green, inner ones more broadly edged green, tertials mostly green with dusky inner webs; underparts green, narrow band of blue in centre of breast and belly, thigh fawn to buff; undertail-coverts green, undertail dark neutral grey; iris dark brown; bill dusky horn; legs dark grey. Sexes similar, female sometimes slightly duller than male. Juvenile is almost entirely dull greyish-brown to dull greenish above, paler below, generally with dingy brownish-grey area on forecrown and side of head, later with hint of brownish-rufous on head; immature much duller than adult, but gradually acquires hint of blue and green in plumage and usually shows contrasting, although dull, head colour. Races differ principally in colour of underparts, colour of rump, colour of lesser wing-coverts, and intensity (or absence) of yellow nape band: *bangsi* differs from nominate in having orange-yellow lesser wing-coverts, blue rump, and throat and entire underparts all blue; *deleticia* is bright blue from throat to vent, has obscure yellow nuchal collar, partly green lesser wing-coverts, blue rump; *nupera* is pale blue from throat to vent, lacks yellow nuchal collar, has only faint yellow on lesser wing-coverts; *toddi* is all green above (including rump) and below, yellow nuchal collar faint or lacking, wing-coverts tinged yellowish-green; *viridissima* is much like previous (including green rump), but duller green to bluish-green below; *albertinae* is almost entirely blue from throat to vent (sides and flanks very narrowly green), has bright yellow on nape reaching smoothly down onto mantle and scapulars, chestnut-brown lesser wing-coverts, light blue rump; *catharinae* resembles last, but entirely blue from lower throat to vent (no green on sides); *parva* is slightly smaller, entirely blue from throat to vent, with prominent yellow nuchal collar. Voice. Call, one of the most distinctive among this vocally undistinguished group, a buzzy "seeaawee", middle part slurred down and then up, typically given at well-separated intervals. Other, less distinctive calls include short scratchy "tssit", also coarse "shree", often given in flight. Song in Trinidad of 5 notes, "seee, seee, seee, tsou tsooy", last 2 notes lower in pitch; in Costa Rica described as 4–6 thin notes descending in pitch and with whining twang.
Habitat. Wide range of humid and wet forest habitats, including tall lowland forest, mossy cloudforest, forest borders, forest clearings with scattered trees, shady coffee plantations and older second growth. Elevational distribution complex: races *bangsi* and *deleticia* mostly at 500–1600 m in E Costa Rica, down to lowlands on Pacific slope from Costa Rica to Canal Zone (Panama), and mainly 500–2100 m on Pacific slope of N Colombia (where replaced at lower elevations by *T. lavinia*); other races occur from lowlands to as high as c. 1800 m. In general more numerous in highlands than in lowlands.
Food and Feeding. Fruits, some arthropods. Of twelve stomachs examined, ten contained only vegetable matter and two contained vegetable and animal matter, including fruit, large seeds, and insects. Fruit accounted for 70% of 564 observations of foraging in Trinidad and 60% of 188 observations in Colombia; combined total of 43 species of fruit recorded at two sites. Fruit of *Miconia*, *Cecropia*, and figs (*Ficus*) predominate in diet. In Costa Rica, arillate fruit of seven species, including the epiphytic vine *Souroubea guianensis* (Marcgraviaceae), were taken. More solitary than most other members of genus. Typically seen singly and in pairs, or for short periods with accompanying juvenile, otherwise not in groups; regularly follows mixed-species flocks, especially those with others of its genus, and joins other birds at fruiting trees. Forages mostly at middle level to canopy heights inside forest, lower at edges and in second growth; in Trinidad and Colombia (W Valle) most foraging heights were above 7·5 m, rarely below 3 m; median foraging height in Colombia 12·2 m. Typically perches upright to take fruits, which swallowed whole, or mashed to remove seed or skin; observed also to snatch berries while in flight, and to peck pieces from large fruits. Readily hangs head downwards to eat catkins of *Cecropia*, and takes tiny protein corpuscles from petioles of *Cecropia*. About 90% of all insect-hunting done on branches (bare or partly mossy) of 5 cm or less in diameter. Forages by leaning head downwards, first on one side and then on other, in stereotyped series of movements as it progresses outwards along branches; gleans prey from sides or beneath live or dead branches; also inspects flowerheads, moss, seed stalks and hanging dead leaves, and occasionally even clings to tree trunks to search bark. Regularly clings to side of hanging vines, but rarely sallies to air for flying prey.
Breeding. In Costa Rica breeding Feb–Sept, sometimes three broods attempted; in Colombia 13 birds in breeding condition Apr–Sept, begging juvenile in Aug, and juveniles in Nov and Mar. In Costa Rica, cup-nest covered on outside with green moss, rootlets, rhizomes and the like, finer material on inside, placed 2–8 m up in foliage; clutch 2 eggs, dull white, spotted with brown, especially in wreath at large end. No other information.
Movements. Resident. Some short seasonal movements, apparently in response to fruit availability, reported in C Panama.
Status and Conservation. Not globally threatened. Locally common to uncommon; widespread. Abundance varies, generally uncommon in lowlands, locally quite common in highlands. Some races apparently secure, with few real threats (e.g. Guianan and Amazonian populations), whereas some montane races have declined considerably and ranges are fragmented because of past and current deforestation. Populations at greatest risk are those in Central America (both in highlands and in lowlands), W Ecuador (especially at lower elevations), and locally throughout Andes of Colombia. The species does occur in most major parks and reserves in lower Central America and throughout its Andean and N Venezuelan range.
Bibliography. 129. Rufous-winged Tanager

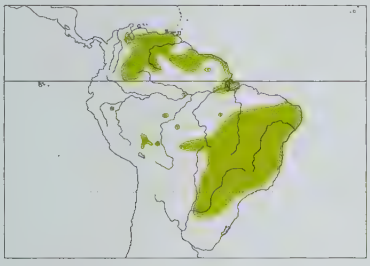
Tangara lavinia

French: Calliste à ailes rousses **German**: Goldflügeltangare **Spanish**: Tangara Alirrufa
Other common names: Lavinia's Tanager

Taxonomy. *Calliste Lavinia* Cassin, 1858, Isthmus of Darién, Panama.
Forms a superspecies with *T. gyrola*; replaces latter in lowlands of wet Chocó–Pacific region. Three subspecies recognized.
Subspecies and Distribution.
T. l. cara (Bangs, 1905) – extreme E Guatemala (Puerto Barrios), Honduras, Nicaragua and Costa Rica S to Panama (to San Blas).
T. l. dalmasi (Hellmayr, 1910) – locally on Pacific slope of Panama (Chiriquí and Veraguas E to E Panamá).
T. l. lavinia (Cassin, 1858) – extreme E Panama (E Darién) and S along Pacific slope of Colombia (from N Chocó), including Gorgona I, to W Ecuador (Pichincha).

Descriptive notes. 12 cm; mean 24 g. Male nominate race has head to well below eye rich glossy chestnut, nape and upper back bright shining golden-yellow, becoming bright glossy green on lower back, rump and upper-tail-coverts; central pair of tail feathers green, remainder dusky with green outer webs; upperwing-coverts and outer primaries bright reddish-chestnut, inner primaries, secondaries dusky, strongly tinged greenish, tertials green with variable dusky tinge, especially on inner webs; mostly bright glossy green below, with central throat and narrow median stripe down centre of breast and centre of belly to vent blue, undertail-coverts green, thigh fawn; undertail dull neutral grey, underwing-coverts greyish; iris dark brown; bill black; legs dark grey. Differs from similar *T. gyrola* in having rufous wings and brighter and more extensive golden on upperparts. Female is duller than male, with head golden-bronze and wing patch olive-bronze, colouring of these areas sometimes reduced in extent, little or no golden-yellow shine on upper back, blue of abdomen paler. Juvenile is rather pale dull green above and below, with head tinged pale yellowish to yellowish-brown (only slight contrast with rest of plumage), wing-coverts and outer flight-feathers pale yellowish-brown, tips of primaries and secondaries dull brown, tail like that of adult; immature similar to juvenile, but flight-feathers more obviously rufous and head dull brownish with tinge of green. Races vary mainly in extent of blue on underparts of male: *cara* is similar to nominate, but only centre of belly blue, rest of underparts green; *dalmasi* is like nominate, but only central throat blue, rest of underparts green, has upper mandible and tip of lower mandible dusky brown, rest of lower mandible mostly neutral grey, base paler; legs neutral grey, undersides of toes honey-yellow. Voice. Not especially vocal. Calls mostly weak, "tseeup" or "tseep", and sharp piercing "zeek"; a thin tittering in flight. In Costa Rica, short wiry song described as "seet-sir tsir-tsir tsir-tsir".
Habitat. Inhabits humid forest and wet forest, and tall second-growth woodland and borders. Lowlands to 750 m in N of range (from Guatemala S to Nicaragua); 400–800 m, occasionally descending lower, in Costa Rica; c. 500–1000 m in Panama; lowlands to c. 500 m (rarely to 1000 m) in Colombia.
Food and Feeding. Fruits and arthropods. Recorded as eating fruits of figs (*Ficus*), *Cecropia* and melastomes in W Colombia. Behaviour not so well known as that of *T. gyrola*. Usually seen singly or in pairs, or with a dependent juvenile, less often in small groups. Regularly forages with mixed-species flocks, at middle heights or higher in forest, but lower along edges. Searches for insects on bare or moss-covered branches, often dead ones, by using a stereotyped lean-down foraging movement typical of many members of genus, inspecting first one side of branch and then the other as it progresses outwards.
Breeding. Few records. Nesting in May in Costa Rica; individual building nest in Jul in Colombia (W Valle). A cup-nest in Costa Rica was composed of mosses mixed with fine rootlets and grass stems, lined with fine black fungal fibres, placed c. 2 m up in a citrus tree near edge of forest. Clutch 3 eggs, white, spotted and speckled with shades of brown, especially on larger end. No other information.
Movements. Largely resident. Some seasonal elevational movements reported on Caribbean slope in Costa Rica, where may descend nearly to sea-level during wet season.
Status and Conservation. Not globally threatened. Uncommon over most of range; absent or quite local in most of E Panama. Generally scarce and local in Central American portion of range; more numerous in Chocó-Pacific lowlands of W Colombia. Occurs in a few protected areas, including Braulio Carrillo National Park (Costa Rica), probably Santa Fé National Park (Panama), and lower end of Farallones de Cali National Park (Colombia). Within this tanager's mostly lowland and foothill range extensive deforestation has taken place and, while intact habitat remains, the species seems vulnerable to continuing fragmentation of its habitat and continued population declines over the longer term.
Bibliography. Burns & Naoki (2004), Carriker (1910), Davis (1972), Dunning (1982), Garrigues & Dean (2007), Haffer (1967b, 1975), Hallinan (1924), Hilty (1997), Hilty & Brown (1986), Isler & Isler (1999), Jahn *et al.* (2002), Land (1970), Marín & Schmitt (1991), Meyer de Schauensee (1964, 1966, 1970a), Naoki (2003c), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Salvin & Godman (1883), Sedano & Burns (2010), Slud (1964), Stiles & Skutch (1989), Wetmore *et al.* (1984).



130. Burnished-buff Tanager

Tangara cayana

French: Calliste passevert **German**: Isabelltangare **Spanish**: Tangara Isabel
Other common names: Rufous-crowned Tanager; Stripe-bellied/Ochre Tanager ("*flava* group"); Arnault's Tanager ("*T. arnaulti*")

Taxonomy. *Tanagra cayana* Linnaeus, 1766, Cayenne, French Guiana.
Forms a superspecies with *T. cucullata*, *T. peruviana*, *T. preciosa*, *T. vitriolina* and *T. meyerdeschauenseei*. An aviary specimen, originally described as *T. arnaulti*, is now believed to be a hybrid between present species and *T. preciosa*. Races form two markedly different populations, in N of range nominate and *fulvescens* ("*cayana* group"), which are predominantly buff below, and mainly S of R Amazon in E Brazil *flava*, *sincipitalis*, *margaritae* and *chloroptera* ("*flava* group"), which are predominantly black below; it has been suggested that the two may represent separate species, but they appear to be united by poorly known intermediate race *huberi*, from Marajó I (at mouth of Amazon). Seven subspecies recognized.

Subspecies and Distribution.
T. c. fulvescens Todd, 1922 – Colombia on both slopes of E Andes at N end (S from Norte de Santander).
T. c. cayana (Linnaeus, 1766) – E Colombia (S to Meta and Vaupés) and Venezuela (S to Cerro Yapacana, in C Amazonas, and Bolívar), locally through the Guianas to coastal NC Brazil (Amapá); isolated populations in NE Peru, SE Peru and adjacent N Bolivia, and C Brazil (R Madeira; R Negro).
T. c. huberi (Hellmayr, 1910) – Marajó I (NE Pará), in N Brazil.
T. c. flava (J. F. Gmelin, 1789) – NE Brazil (EC Pará; C Maranhão and N Ceará S to N Goiás and S Bahia).
T. c. sincipitalis (Berlepsch, 1907) – Goiás (except N), in EC Brazil.
T. c. margaritae (J. A. Allen, 1891) – C Brazil (Mato Grosso).
T. c. chloroptera (Vieillot, 1819) – SE Brazil (Minas Gerais, São Paulo and Paraná to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).
Descriptive notes. 13–14 cm; 15·2–22·5 g. Colourful tanager with two distinctive plumage types, colours of both varying with angle of light. Male nominate race has crown rufous (varying to coppery or golden-rufous), lowermost forehead, lores, area through eye and back to rear ear-coverts

black, forming prominent mask; upperparts, including uppertail-coverts, shining burnished buff (greenish-gold to straw-gold); tail dusky blue, central feathers mostly dull bluish, outermost pairs edged dull pale greenish-blue; lesser upperwing-coverts mainly pale blue-green, median and greater coverts dusky, broadly edged and tipped pale blue-green, primary coverts black, narrowly edged pale blue-green; flight-feathers blackish, edged pale bluish-green, tertials black with outer half of each feather pale blue-green; below mostly shiny buff, sometimes with strong to weak violet-grey tinge on throat and median underparts; iris dark brown; bill blackish; legs dark grey. Female is much duller than male, crown dull coppery rufous, mask duller black, mantle and back dull smoky greyish-green, rump paler smoky yellowish-green; tail tinged dull greenish (not blue); wing and its coverts like those of male, but pale greenish (not bluish); throat and breast dingy greyish, becoming dull smoky greyish to greenish-buff on lower underparts, undertail-coverts mainly buff. Juvenile is very dull smoky greyish with green tinge above, paler below, with greenish edgings on wings and tail, slight brownish-rufous tinge on forecrown, no mask; immature male has dull rufous crown (can be obscure) and dusky mask reminiscent of adult, but much duller. Races differ mainly in colour and pattern of male underparts: *fulvescens* is like nominate, but slightly larger and overall slightly paler, with more silvery (less buffy) body plumage; *chloroptera* differs in having black on side of face extending down across throat and entire median underparts to belly, sharply contrasting with deep buff of rest of underparts, also has underwing-coverts black, female much duller, often with little more than tinge of rufescent on crown, mask faint, throat dull whitish, underparts dull pale greyish-buff with greenish tinge, undertail-coverts buff; *sincipitalis* and *margaritae* are similar to previous, but with black below slightly less extensive and underwing-coverts paler, deep brownish-buff; *flava* also closely resembles *chloroptera*, but black below less extensive and underwing-coverts buffy white; *huberi* is intermediate between N & S races, underparts nearest to *chloroptera*, but with black duller and less well defined, and back, flanks and undertail-coverts paler buff, like nominate. Voice. At times fairly vocal, especially for its genus. Call a buzzy "tzzit", given when perched or in flight. Infrequently heard song a rather long, echo-like (or pulsating), buzzy trill, "sizza' sizza'sizza...", 10 or more notes in c. 2–3 seconds, which sounds like two birds singing simultaneously; reminiscent of songs of *T. heinei* and *T. vitriolina*.

Habitat. Drier open habitats, including ranchland, borders of gallery and savanna woodland, and scrubby wasteland; regularly in gardens and trees around ranch buildings. In Venezuela, lowlands to 2500 m N of R Orinoco and to c. 1800 m S of Orinoco; elsewhere, mainly in lowlands to c. 1000 m; at 1000–1150 m in Peru.

Food and Feeding. Fruits, some arthropods; overall, appears to eat mostly fruit and seems not to capture many insects. Of 19 stomachs examined, 18 contained only vegetable matter and one only animal matter; contents included berries, fruit, seeds of *Michelia champaca* (Magnoliaceae), *Schinus* (Anacardiaceae), guava (Myrtaceae), loquat (*Eriobotrya japonica*), and wasps (Hymenoptera). Mistletoe berries (Loranthaceae) found in other stomachs. Observed to consume termites (Isoptera), *Cecropia* catkins, and fruits of palms, and often pecks pieces from large fruits, including papayas (*Carica papaya*) and bananas; in C Brazil also *Hamelia* fruit. In Venezuela and Suriname seen to take a variety of fruit (and rice) from birdfeeders, and fruit from hotel dining rooms. An "open-country" tanager encountered singly, in pairs and in small family groups about equally; does not follow mixed-species flocks (few of which form in areas inhabited by this species), but does sometimes gather with other birds in fruiting trees and at feeding trays. Forages from low in bushes to treetops. Often seen as it flies by, travelling to some distant shrub or tree, where it eats small fruits and berries and sometimes leans down a few times to inspect alternate sides of branches for insects.

Breeding. Breeding reported Dec–May In Venezuela, Jan–Apr, Jul and Nov in Suriname, and Oct and Nov in S Brazil. Open cup-nest of rootlets, leaves and grass, lined with finer material, placed amid leaves 1·5–2·5 m up in isolated tree. Clutch 2 eggs, whitish, pale blue, lavender or brownish-white, marked with brown, especially around larger end. No other information.

Movements. Resident. Some local movements in response to availability of fruit.

Status and Conservation. Not globally threatened. Common and widespread across much of range. Occurs in many parks and other protected areas over its vast range, thrives in degraded areas, and has profited, at least locally, from conversion of forest into open or semi-open areas with scattered trees. Given the increasing amount of drier open habitat available to this species, it is unlikely to face any risks in the near future or the longer term.

Bibliography. Allen (1891), Bond (1951b), de Brito & Pereira (2006), Burns & Naoki (2004), Cherrie (1916), Contreras (1979a), Descourtilz (1852), Diamond & Lovejoy (1985), Dunning (1982), Erickson & Mumford (1976), Forbes (1881), Friedmann & Smith (1950), Fry (1970), Ginés *et al.* (1951), Haverschmidt (1952, 1955, 1968, 1970a, 1975), Haverschmidt & Mees (1994), Hellmayr (1936), Hilty (2003), Hilty & Brown (1986), Ingels (1971b), Isler & Isler (1999), McCarthy (2006), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Mitchell (1957), Moojen *et al.* (1941), Naoki (2003c), Narosky & Di Giacomo (1993), Ogilvie-Grant (1912), Parker & Goerck (1997), de la Peña & Rumboll (1998), Ramo & Busto (1984), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Santos (1948), Sazima (2008), Schäfer & Phelps (1954), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sick (1985, 1993), Snethlage (1927, 1928a), Snyder (1966), Souza (2002), Thomas (1982), Tostain *et al.* (1992), Vandieken (2008), Willis & Oniki (2003), Zimmer (1943c).

131. Lesser Antillean Tanager

Tangara cucullata

French: Calliste dos-bleu **German**: Rotkappentangare **Spanish**: Tangara Antillana
Other common names: Hooded Tanager!

Taxonomy. *A.[glaia] Cucullata* Swainson, 1834, no locality = Grenada.
Forms a superspecies with *T. cayana*, *T. peruviana*, *T. preciosa*, *T. vitriolina* and *T. meyerdeschauensei*. Two subspecies recognized.

Subspecies and Distribution.
T. c. versicolor (Lawrence, 1878) – St Vincent, in S Lesser Antilles.
T. c. cucullata (Swainson, 1834) – Grenada, in S Lesser Antilles.

Descriptive notes. 14–15 cm; 25·7–30·3 g (*versicolor*). Male nominate race has crown dark maroon-chestnut, barely contradting with blackish mask from lores to behind eye, tinged blue-green on rear ear-coverts; hindneck to uppertail-coverts pale yellowish-buff with slight greenish tinge; upperwing and its coverts, tertials and tail blackish, heavily edged bluish-green; underparts lavender mixed with some buff, dark spotting on chin and throat, undertail-coverts tawny-buff; iris dark brown; bill black; legs dark horn-grey. Female is much duller than male, with strong greenish tinge in upperparts, and greenish-grey underparts. Juvenile like adult but much duller, with only hint of dark mask; may show little or no rufous on crown. Race *versicolor* is slightly larger than nominate, crown paler (more contrast with mask), and overall plumage brighter. Voice. Call a simple "chirp"; song a series of clear whistles ending in a twitter, "weet-weet-weet-witwitwitwit".

Habitat. Dry and moist forest, wooded borders, second growth, parks and gardens, and montane thickets throughout; also arid scrub on Grenada and also montane rainforest on St Vincent. Occurs at all elevations, but more numerous at higher levels.

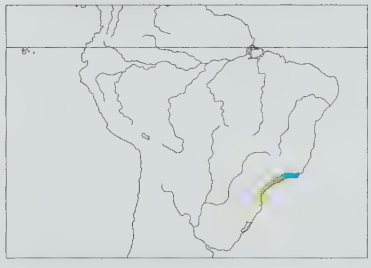
Food and Feeding. Fruits and arthropods. Variety of fruit taken, including figs (*Ficus*) and mangos (*Mangifera*), and apparently particularly fond of sour-sop (*Annona*). Occurs in pairs and small flocks, frequently gathering at fruiting trees. Forages from low shrubs to treetops. Gleans arthropods from leaves; also sallies short distances to air.

Breeding. Season Apr–Jul. Reported as stealing material from nests of other birds; open cup-shaped nest built c. 1·8–6 m up in fork of bush or tree, often near human dwelling. Clutch 2 eggs, white to bluish with brown and grey markings, especially in ring at larger end. No further information available.

Movements. None reported.

Status and Conservation. Not globally threatened. Restricted-range species: present in Lesser Antilles EBA. Uncommon on both islands on which it occurs. Has extremely small global range, but believed not to be declining significantly. Like allied *T. cayana*, this species utilizes scrub and disturbed and settled areas; may profit from or, at least, not be adversely affected by many of the environmental changes that result from human activities.

Bibliography. Anon. (1998), Bond (1928b, 1961), Burns & Naoki (2004), Clark (1905), Devas (1954), Isler & Isler (1999), Lack & Lack (1973), Oberle (2008), Ogilvie-Grant (1912), Raffaele *et al.* (1998), Sedano & Burns (2010), Wells (1886).



132. Black-backed Tanager

Tangara peruviana

French: Calliste à dos noir **German**: Schwarzmanteltangare **Spanish**: Tangara Dorsinegra
Other common names: Polymorphic Tanager (when treated as conspecific with *T. preciosa*)

Taxonomy. *Tanagra peruviana* Desmarest, 1806, Peru; error = Rio de Janeiro, Brazil.
Forms a superspecies with *T. cayana*, *T. cucullata*, *T. preciosa*, *T. vitriolina* and *T. meyerdeschauenseei*. Has been considered conspecific with *T. preciosa*, the two then being regarded as partially localized morphs of a single species, differing in colour of mantle and back; polymorphism, however, not known to occur in any other member of genus and, further, differences in breeding distribution and habitat suggest that the two are best regarded as separate species. Monotypic.

Distribution. SE Brazil from Espírito Santo S along coast to NE Rio Grande do Sul.

Descriptive notes. 14 cm; 18·5–25·5 g. Male has crown, nape and side of head rufous-chestnut, small dark mask around lores and eye, mantle black, scapulars and back to rump opalescent coppery-straw to pale straw-yellow, often with greenish tinge; lesser and median upperwing-coverts opalescent straw (conspicuous), greater coverts dusky green, broadly edged and tipped opalescent straw; flight-feathers and tail dusky, heavily edged blue-green to blue, tertials mostly blue-green with dusky inner webs, and often with straw-yellow edging; short, inconspicuous straw-coloured malar mark, merging into shining bluish-green on throat, breast, sides and flanks; centre of belly pale yellowish-opal, undertail-coverts dull rufous; iris dark brown; bill black; legs grey. Female is considerably duller than male, has crown and nape pale cinnamon-rufous, mask less clearly marked, upperparts dusky-olive, wing, including coverts, and tail dusky with greenish edgings, underparts dingy silvery green, paler than upperparts, undertail-coverts tinged orange-cinnamon; very much like female of *T. preciosa*. Juvenile like adult but much duller, initially with little of adult pattern or colour evident. Voice. Call a high thin "seeeeek", clear and notably drawn out; also brief high "ti" or "tic" notes, much like those of many congeners. No song described; like many members of genus, either rarely sings or song is brief and easily overlooked.

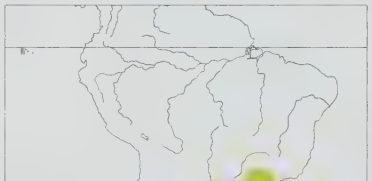
Habitat. Coastal sandy-soil forest and scrub (*restinga*), also woodland borders, secondary forest, trees and brush at edges of pastures, gardens, orchards and vegetation along streams. From coast and lowlands to foothills, to c. 700 m. Apparently mainly coastal when breeding.

Food and Feeding. Reported feeding on berries and other fruits, including those of *Schinus*; also as eating sweet excretions of plant lice. Faecal analyses indicate diet of 67% fruit (by frequency), mixed with insects and spiders (Araneae). Occurs alone, in pairs and in families or small groups. Alternates active foraging with periods of relative quiet, when it perches atop shrubs and small trees. Behaviour much like that of *T. preciosa*.

Breeding. Reported occasionally to occupy remains of bulky nests of Monk Parakeet (*Myiopsitta monachus*). No other information.

Movements. Apparently largely migratory. Occurs in Espírito Santo and Rio de Janeiro primarily as austral winter visitor in Apr–Sept; very few records to S in Paraná, Santa Catarina and Rio

On following pages: 133. Chestnut-backed Tanager (*Tangara preciosa*); 134. Scrub Tanager (*Tangara vitriolina*); 135. Green-capped Tanager (*Tangara meyerdeschauenseei*); 136. Rufous-cheeked Tanager (*Tangara rufigenis*).



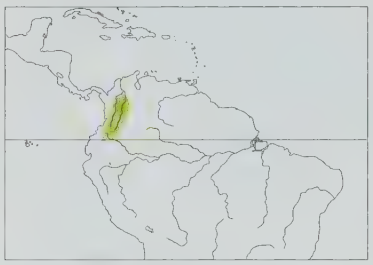
Grande do Sul, however, and movements need confirmation. Local fluctuations in numbers, apparently due to seasonal movements, reported in Rio de Janeiro and around São Paulo.
Status and Conservation. VULNERABLE. Restricted-range species: present in Atlantic Forest Lowlands EBA. Rare and local. Total population estimated at fewer than 10,000 individuals, and declining. No definite records from Santa Catarina since 1930s; first recorded in Rio Grande do Sul in 1999, and only a couple of known records since then. An important threat is loss of *restinga* habitat to beachfront real-estate development and other tourist facilities. Suitable habitat in Rio de Janeiro and Paraná now largely destroyed. Trapping for cagebird trade a minor threat, but could become important as habitat continues to disappear and populations decline further. Occurs in six small protected areas, although enforcement of protection laws in these areas is ineffective. A more comprehensive understanding of this species' seasonal distribution and population trends is urgently required.
Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Descourtilz (1852), Hellmayr (1936), Isler & Isler (1999), McCarthy (2006), Meyer de Schauensee (1966, 1970a), Moraes & Krul (1997), Novaes (1950), Palanqué (2005), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Rosa & Agne (2010), Sick (1985, 1993), Sick & Pabst (1968), Souza (2002), Stattersfield & Capper (2000).

133. Chestnut-backed Tanager

Tangara preciosa

French: Calliste à dos marron **German**: Prachttangare **Spanish**: Tangara Preciosa
Other common names: Polymorphic Tanager (when treated as conspecific with *T. peruviana*); Arnault's Tanager ("*T. arnaulti*")

Taxonomy. *C.[allispiza] preciosa* Cabanis, 1851, Rio Grande do Sul, Brazil.
Species has sometimes been referred to as *T. castanonota*, but present name has priority. Forms a superspecies with *T. cayana*, *T. cucullata*, *T. peruviana*, *T. vitriolina* and *T. meyerdeschauenseei*. Has been considered conspecific with *T. peruviana*, the two then being regarded as partially localized morphs of a single species, differing in colour of mantle and back; polymorphism, however, not known to occur in any other member of genus and, further, differences in breeding distribution and habitat suggest that the two are best regarded as separate species. An aviary specimen, originally described as *T. arnaulti*, is now believed to be a hybrid between present species and *T. cayana*. Monotypic.
Distribution. SE Paraguay, NE Argentina (Misiones S to Entre Ríos, and at least formerly to mouth of R La Plata and N Buenos Aires), coastal SE Brazil (São Paulo S to Rio Grande do Sul) and Uruguay.



Descriptive notes. 14 cm; 22–24 g. Male has entire crown, nape, side of head, mantle and back rich golden-rufous, scapulars, rump and uppertail-coverts yellowish-opal, longest uppertail-coverts tinged green; upperwing-coverts shining yellow-buff, flight-feathers and tail black, edged greenish-blue; inconspicuous straw-coloured malar stripe merging into shining blue-green on throat and underparts, including breast, sides and flanks; centre of belly pale yellowish-opal, undertail-coverts rufous; iris dark brown; bill black; legs grey. Female is much duller than male, has crown and nape rufescent, otherwise dull greyish-green above, wing, including wing-coverts, and tail dusky with greenish edgings, throat and underparts dingy silvery green, paler than above, undertail-coverts tinged cinnamon; essentially identical to female of *T. peruviana*. Juvenile like adult but much duller. VOICE. Call a squeaky "zeeek!" or "zurk". Song 4–5 high, lisping notes, "seeeee seeeee seeeee seeeee seeeee", all on same pitch.
Habitat. Forest borders, especially where *Araucaria* trees occur, and in woodlots, gardens, and shrubby areas in otherwise partly open areas. Lowlands to c. 1000 m.
Food and Feeding. Fruits and arthropods. Takes a variety of fruit, such as *Schinus* and loquat (*Eriobotyra japonica*), also cultivated fruits. Found in pairs and in small groups, often with mixed-species flocks. Feeds from low down to high up; searches for insects in tree foliage.
Breeding. One nest-site in Rio Grande do Sul was 10 m up in thick fronds of an araucaria tree. No other information.
Movements. Some local seasonal movements, apparently in response to shifting food supplies. Those in extreme S of Brazilian range in Rio Grande do Sul, as well as all of Uruguay, N Argentina and Paraguay, are thought to be almost entirely migratory, moving N for coldest months.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Most numerous in Rio Grande do Sul, e.g. in Aparados da Serra National Park. Occurs also in a number of other protected areas in SE Brazil, and as far W as Iguazú National Park, in Argentina. Because this species is able to utilize a variety of forest-edge and disturbed habitats, it is unlikely to become at risk, at least in the short term. Can cause some damage locally to cultivated fruits.
Bibliography. 134. Scrub Tanager

Tangara vitriolina

French: Calliste vitriolin **German**: Rotscheiteltangare **Spanish**: Tangara Matorralera

Taxonomy. *C.[allispiza] vitriolina* Cabanis, 1850, Colombia.
Forms a superspecies with *T. cayana*, *T. cucullata*, *T. peruviana*, *T. preciosa* and *T. meyerdeschauenseei*. Monotypic.
Distribution. Colombia from Pacific slope of W Andes E to W slope of E Andes (Norte de Santander) and E slope of E Andes (E Cauca), S to NW Ecuador.
Descriptive notes. 14 cm; 18·4–26·8 g. Relatively dull tanager, with dingier plumage than that of congeners. Male has crown rufous, lores, ocular area and postocular area dusky, forming fairly conspicuous blackish mask; upperparts mainly shining greyish-green to shining silvery green, rump paler opalescent green, uppertail-coverts shining greyish-green (like back); central tail feathers dull greyish-blue, outer feathers dusky with outer half dull greyish-blue, outermost pair with faint blue-green edges; upperwing-coverts dusky, lesser and median coverts broadly tipped dull pale

green, greater coverts with distal half of each feather dull pale green, primary coverts, flight-feathers and tertials blackish, prominently edged pale blue-green; throat, chest, breast and sides shining pale bluish-grey to greenish-grey (varies with light, but typically with bluish tinge), centre of lower breast and belly pale glaucous, tinged buff, undertail-coverts buff to whitish-buff; iris brown; bill greyish-horn; legs dusky horn. Female is generally similar to male, but duller, with back and rump dull pale greyish-green (not bluish), tail tinged greenish, wing-coverts and flight-feathers edged paler glaucous-green (not blue-green), throat and underparts dull greyish with only hint of greenish-blue, and lower breast lacking bluish tinge, belly and undertail-coverts more extensively buffy. Juvenile is almost completely dingy pale brownish-grey and devoid of markings; immature much duller than adult, but typically some rufous coloration on crown and indication of darker face mask, sometimes weak greenish tinge on back, wing-coverts and flight-feathers, and throat buffy white, underparts dull. VOICE. Call a shrill, buzzy "ziit". Song lisping and buzzy, beginning slowly, then accelerating quickly into buzzing or pulsating trill, "slip...slip, slip slip-sit'sit'it'it'it'it'it'it'it'iiiiiiii'i'it'it", typically repeated a few times at short intervals, then not heard again for long periods.
Habitat. Dry scrubby or cultivated areas, overgrown pastures, agricultural areas, brushy fence rows, and arid intermontane valleys; often around human habitations. Mostly 500–2200 m (recorded 300–3000 m) in Colombia; 800–2500 m, occasionally higher, in Ecuador.
Food and Feeding. Fruits and arthropods. May take more insects than fruit; recorded taking melastome berries. One stomach contained insects. Usually seen singly, in pairs and in families; commonly comes to fruiting trees, often when other birds present, but rarely found with mixed-species flocks. Forages from low in shrubs to tops of tall trees and. Forages by hopping and peering, behaviour somewhat like that of a vireo (Vireonidae); occasionally also peers head down on alternate sides of branches, as do many congeners. Also peers in outer foliage, epiphytes, flowers and seedheads.
Breeding. May breed most of year: in Colombia, fledglings in Feb and juvenile with adult in Mar in Cauca, fledglings in May in Cundinamarca, adults carrying food in mid-Aug in W Valle, and four birds in breeding condition Jun–Aug at N end of W & C Andes, one in Jan in upper Magdalena Valley, two in Mar near Cali and one in Nov in upper Patía Valley. Open cup-nest of moss and fine fibres, near Bogotá placed 3–6 m above ground near end of branch. Clutch 2 eggs, white or tinged blue, green or cream, and boldly marked with lilac and/or brown, especially at large end. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Common. Has expanded its range as a result of deforestation and increased disturbance, and is now found in wetter regions and at higher elevations than in the past. Believed to have arrived in 1960s on Sabana de Bogotá (2600 m), where remained rare until 1990s, but now well established. Similarly, following deforestation, has extended locally into wet Chocó–Pacific slope, a locality where formerly did not occur; more recently still, has been found on E slope of E Andes in E Cauca, where it has followed clearings and settlement. Does not face any significant threats in immediate or longer term.

135. Green-capped Tanager

Tangara meyerdeschauenseei

French: Calliste de Schauensee **German**: Grünkappentangare **Spanish**: Tangara Coroniverde

Taxonomy. *Tangara meyerdeschauenseei* Schulenberg and Binford, 1985, 2 km north-east of Sandia, c. 2175 m, Puno, Peru.
Forms a superspecies with *T. cayana*, *T. cucullata*, *T. peruviana*, *T. preciosa* and *T. vitriolina*. Monotypic.
Distribution. SE Peru (E Puno); probably also W Bolivia (Madidi National Park, in La Paz).

Descriptive notes. 14 cm; one male 26·5 g, one female 25·4 g. Dull tanager with little plumage contrast, looking mainly opalescent buff with greenish wings and tail in field; colours vary with angle of light, blues and green predominating when light behind observer, otherwise buff or straw predominant. Crown is opalescent greenish-straw to ochre, with forehead and obscure eyebrow shading to dull bluish-green; lores and ocular area dark grey, forming ill-defined mask; mantle and back pale mealy green with buff tinge, sides of back (near scapulars) somewhat bluer than centre of back, and entire region can appear coppery to creamy buff; scapulars greenish, varying to greyish-turquoise; rump and uppertail-coverts greenish-straw to bluish-green; central pair of tail feathers dark grey near shaft, otherwise glossed with blue-green, outer feathers (except outermost pair) grey on inner web and near shaft, with outer webs blue-green (varying to coppery cream-buff), outermost pair grey, very narrowly and faintly edged with blue-green on outer third of outer web; lesser and median upperwing-coverts glaucous green, greater coverts dusky, broadly edged and tipped light green to greyish-turquoise, primary coverts, flight-feathers and tertials dusky, edged light green to greyish-turquoise; throat and underparts dull cream with faint lavender tinge, undertail-coverts tinged cinnamon; iris brown; upper mandible blackish, lower mandible grey with blackish tip; legs plumbeous grey. Sexes similar, but female greener overall, with crown tinged tawny, pale greenish-straw below. Juvenile undescribed. VOICE. Call a rather dull, heavy "chup". No song has been recorded.
Habitat. Forest edges, gardens and partly cleared slopes that may formerly have been covered with scrub or dry forest; recorded at 1750–2200 m. Believed originally to have been confined to arid, semi-open, intermontane scrub.

Food and Feeding. Reported as taking small fruits and arthropods. Usually seen in pairs or in groups of 3–4 individuals. Observed to forage in fruiting trees; probably also takes fallen fruit on ground. No other information.
Breeding. Two birds with enlarged gonads in Nov. No other information.
Movements. No information; possibility of some seasonal movement between arid scrub and more humid sites has been suggested.
Status and Conservation. VULNERABLE. Restricted-range species: present in Upper Inambari Valley Secondary Area. Fairly common to locally common. Has extremely small known global range, estimated at c. 380 km². In SE Peru, known to occur at three sites in Puno, including head of R Inambari near Sandia, and W side of Abra de Maruncunca. In Bolivia, a published sight record of a pair in Nov 2001 near Tokoaque (at 2150 m), in Madidi National Park, c. 50 km E of R Inambari; as habitat very unlike that utilized by this species in Peru, validity of record is subject to verification. While some doubt remains about original habitat occupied by this species, its presence in semi-arid habitats and settled areas in dry regions of extreme SE Peru (Sandia region) suggests that it probably has always occurred in drier, semi-open terrain; thus, it is able to utilize highly modified habitats. Population trends undocumented, but recent observations suggest the species is increasing in numbers, and may be expanding in conjunction with local habitat degradation.
Bibliography. Anon. (1986, 2010a), Burns & Naoki (2004), Butchart & Stattersfield (2004), Clements & Shany (2001), Fjeldså & Krabbe (1990), Hennessey & Gomez (2003), Hesse (2006), Isler & Isler (1999), Naoki (2003b), Parker & Bailey (1991), Remsen *et al.* (2010), Robbins (2010), Schulenberg & Binford (1985), Schulenberg *et al.* (2007), Ridgely & Tudor (1989, 2009), Sedano & Burns (2010), Stattersfield & Capper (2000).

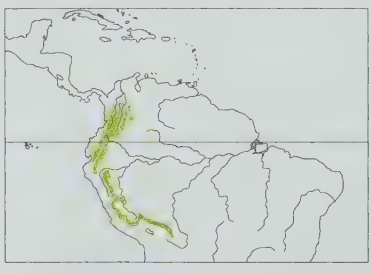
136. **Rufous-cheeked Tanager**

Tangara rufigenis

French: Calliste à joues rousses **German**: Rotwangentangare **Spanish**: Tangara Carirrufa

Taxonomy. *Calliste rufigenis* P. L. Sclater, 1857, Caracas, Venezuela.
Monotypic.
Distribution. N Venezuela: N end of Andes in S Lara, mountains of Yaracuy (Sierra de Aroa), coastal cordillera from Carabobo E to Miranda, and interior cordillera in S Aragua (Cerro Golfo Triste).
Descriptive notes. 13 cm; 16–17·4 g. Rather small bluish-green tanager with small rufous mask. Has lores and chin back to rear ear-coverts rufous; rest of head to nape, mantle and back smoky bluish-green, rump and uppertail-coverts pale blue (not contrasting strongly with rest of plumage); tail blackish, feathers edged dull blue-green; upperwing and its coverts dusky, lesser coverts edged pale blue, greater coverts edged pale greenish-blue, flight-feathers edged cinnamon-brown, edging becoming pale greenish on tertials; shining bluish-green below, slightly paler on throat, with centre of belly and undertail-coverts cinnamon-rufous to pale rufous; iris dark brown; bill blackish; legs dark grey. Sexes similar. Immature is much duller than adult, but usually with hint of rufous on cheek. VOICE. Contact or foraging call a weak "tsit", sometimes in rapid series. No song described.

Habitat. Humid and wet forest, forest borders, and second growth or disturbed vegetation in small forest openings; also landslides on steep slopes, especially where there are many *Miconia* trees and other melastomes. At 900–2050 m.
Food and Feeding. Fruits, also arthropods. Takes variety of small berries from species of melastome. Occurs alone or, more often, in pairs or small groups, occasionally of up to eight individuals, regularly with mixed-species flocks containing other members of its genus. Active and lively, foraging mostly in outer foliage, primarily in middle and upper levels of trees, also sometimes down to eye level in smaller trees and shrubs along forest borders. Generally energetic and fast-moving, hopping quickly along small terminal limbs; peers at twigs and especially at foliage in restless manner, almost like a New World warbler (Parulidae).
Breeding. No information.
Movements. Some downslope movement during rainier months, May–Sept, in Henri Pittier National Park.
Status and Conservation. Not globally threatened. Restricted-range species: present in Cordillera de la Costa Central EBA. Uncommon; generally at low density. Suitable habitat for this species preserved in a few parks and watersheds, notably Henri Pittier National Park (in Aragua), Palmichal Reserve (in Carabobo), and possibly Terepaima National Park (in Lara). It is known to occur in Sierra de Aroa, a large forested area that does not include any protected sites. Population estimates for this tanager require clarification; the species may well require listing as Near-threatened or even Vulnerable.
Bibliography. Hilty (2003), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1963), Ridgely & Tudor (1989, 2009), Schäfer & Phelps (1954), Wetmore (1939).



137. **Golden-naped Tanager**

Tangara ruficervix

French: Calliste à nuque d'or **German**: Rotnackentangare **Spanish**: Tangara Nuquirrufa
Other common names: Orange-rumped Tanager; Orange-naped/Yungas Tanager (*fulvicervix*)

Taxonomy. *Tanagra ruficervix* Prévost and Des Murs, 1846, no locality = Bogotá, Colombia.
S race *fulvicervix* sometimes treated as a separate species. The three N races differ markedly in plumage from S ones, and more than one species may be involved. Race *amabilis* may intergrade with *inca* in C Peru. Six subspecies recognized.

Subspecies and Distribution.
T. r. ruficervix (Prévost & Des Murs, 1846) – Andes of Colombia on both slopes of W & C ranges (from Antioquia) and E range (W slope S from Santander, and E slope from Cundinamarca–Meta border S to Cauca and Nariño).
T. r. leucotis (P. L. Sclater, 1851) – W Ecuador (S to El Oro).
T. r. taylori (Taczanowski & Berlepsch, 1885) – E Ecuador (S to W Loja) and extreme N Peru (N of R Marañon, in vicinity of Cajamarca).
T. r. amabilis J. T. Zimmer, 1943 – E slope of Andes in N Peru (S at least to Huánuco).
T. r. inca Parkes, 1969 – S Peru (Junín S to Puno).
T. r. fulvicervix (P. L. Sclater & Salvin, 1876) – E slope of Andes in extreme SE Peru (near Bolivian border) and Bolivia (La Paz and Cochabamba).

Descriptive notes. 13 cm; 16–22·2 g. Small, mostly blue tanager, two populations differing distinctly in plumage. Male nominate race is mainly turquoise-blue; lores, chin, forecrown and ocular area black, small reddish-golden band on rear crown extending around in an arc and almost reaching eye from behind, this band bordered above and below with violet, ear-coverts turquoise-blue, the upper ones with conspicuous whitish or golden tips; mantle and back mainly black, feathers rather narrowly scaled with blue (imparting streaked appearance), lower back, rump and uppertail-coverts bright unspotted blue, or occasionally with

obscure blackish mottling; tail dark blue, feathers narrowly edged light blue; lesser upperwing-coverts mostly bright blue (often hidden), median coverts black, edged and tipped blue, greater coverts black, edged blue, primary coverts blackish, flight-feathers and tertials black, basal half of flight-feathers and entire length of all secondaries and tertials narrowly edged pale blue; throat, breast, sides and flanks mostly bright blue, sides and flanks somewhat mottled greyish-black, centre of lower breast and belly contrastingly buff, becoming darker cinnamon-buff on undertail-coverts; iris dark brown; bill black; legs dusky. Female is similar to male, but slightly duller, with marginally smaller rear crown patch. Juvenile is mainly sooty grey to brownish-grey, including entire head, has back faintly tinged bluish, wing-coverts, flight-feathers and tail sooty with dull blue edgings, below is dingy grey, paler than above, and becoming dull buff on belly and undertail-coverts. Races differ mainly in plumage coloration, three races in S much darker: *leucotis* is much like nominate, but slightly darker blue above and below, forecrown tinged blue, hindcrown slightly darker, more golden-rufous, also has longer bill and shorter wing and tail than nominate; *taylori* differs from previous in having blue colours slighter greener, forecrown patch ultramarine, hindcrown patch slightly paler golden-yellow and reaches down to upper edge of ear-coverts, which are fringed whitish and sometimes with orange-rufous; *amabilis* is darker blue than preceding N races but palest of S races, has blackish forecrown, greenish tinge on back, with buff to fawn lower underparts (darker than N races but palest of S races); *inca* is dark blue, darker than previous, black of face mainly confined to lores and ocular area, and band on nape rufous (not golden-buff) and without violet borders; *fulvicervix* is darkest race, differs from last in having distinctly darker, richer and more purplish-tinged blue on underparts. Voice. During foraging gives weak "chip" or "tic" notes, often in rapid, excited bursts. No song has been described.

Habitat. Humid and wet forest borders, older second growth and sometimes shrubby pastures; less often inside wet mossy forest. At c. 1100–2500 m, but in most areas above 1500 m; reported as low as 900 m in Ecuador and as high as 2500 m in Peru.

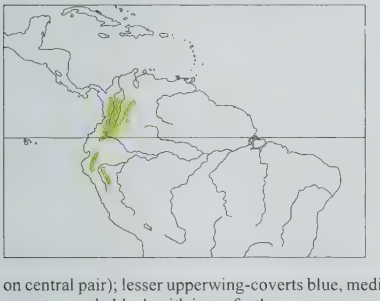
Food and Feeding. Takes variety of small fruits and berries, including those of melastomes, figs (*Ficus*), *Morus*, and *Cecropia*; also arthropods. One stomach contained vegetable matter, another both vegetable and animal matter, including fruit pulp, seeds, berries and insects. Occurs in lively pairs, somewhat less often in small groups of 3–5 individuals, about equally with mixed-species flocks and independently of them. Forages at c. 5–25 m up, generally fairly high (median 12 m in W Valle del Cauca, in Colombia). Searches for insects with classic head-down peering along alternate sides of bare to partly mossy branches; also flutters and sallies short distances to foliage for insects.

Breeding. In Colombia, nest found in Apr in W Valle, and dependent juvenile in Sept and seven birds in breeding condition in Feb–Jun in C Andes. Cup-nest; clutch 2 eggs, apparently not described. In captivity, incubation c. 14 days, and adults reportedly fed some food to chicks by regurgitation (needs verification). No other information.

Movements. Presumably resident.

Status and Conservation. Not globally threatened. Uncommon to fairly common. Perhaps more numerous locally in S portions of range. Occurs in a number of protected areas, including Tatamá, Farallones de Cali and Cueva de los Guácharos National Parks and Río Blanco de Manizales, Tambito and El Pangan Nature Reserves (Colombia), and probably Cotocachi-Cayapas, Sangay, El Cajas and Podocarpus National Parks (Ecuador); also Manu National Park (Peru) and Madidi National Park (Bolivia). The species is vulnerable to extensive deforestation, which is occurring almost throughout its range. Within its range, however, considerable amount of intact unprotected habitat exists and, at least in the short term, risks to this species appear small.

Bibliography. Berlepsch (1911), Burns & Naoki (2004), Chapman (1926), Donegan & Dávalos (1999), Donegan *et al.* (2007), Dunning (1982), Fjeldså & Krabbe (1990), Hellmayr (1936), Hilty (2009a), Hilty & Brown (1986), Isler & Isler (1999), Kleefisch (1995), Lysinger *et al.* (2005), Mee *et al.* (2002), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Miller (1963), Moore *et al.* (1999), Murray (1970), Naoki (2007), Parkes (1969b), Remsen *et al.* (2010), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schulenberg *et al.* (2007), Sedano & Burns (2010), Walker (2001), Weske (1972), Zimmer (1943b, 1943c).



138. Metallic-green Tanager

Tangara labradorides

French: Calliste vert **German**: Schwarznackentangare **Spanish**: Tangara Verdinegra

Taxonomy. *Tanagra* (*Aglaia*) *labradorides* Boissonneau, 1840, Santa Fé de Bogotá, Colombia.
Two subspecies recognized.

Subspecies and Distribution.
T. l. labradorides (Boissonneau, 1840) – Andes of Colombia (both slopes of W & C Andes in Antioquia; W slope of E range S from Cundinamarca, also one record on E slope at Guaicaramo; both slopes in Cauca and Nariño) and Ecuador (W slope S to Pichincha, and very locally E slope S to Loja and Zamora Chinchipe).
T. l. chaupensis Chapman, 1925 – N Peru (E slope of Andes in Amazonas and N San Martín).

Descriptive notes. 12 cm; 13–16·4 g. Small tanager, plumage colour varying with angle of light; relatively long bill. Male nominate race is mostly shining opalescent bluish-green; forehead and broad eyebrow pale opalescent to straw with hint of greenish (especially from above eye rearwards); lores and small area surrounding bill (lowermost forehead and chin) black, broad black central crownstripe extending to nape; scapulars black, mantle and back black, variably mixed with shining opalescent green, lower back, rump and uppertail-coverts mostly shining green with opalescent tinge; tail black, feathers narrowly edged green (obscure on central pair); lesser upperwing-coverts blue, median coverts dusky, broadly tipped bluish, greater coverts mostly black with inner feathers very narrowly edged bluish-green, all flight-feathers dusky, narrowly edged bluish-green; throat and underparts mostly shining opalescent green (weak bluish tinge from lower side of head to chest), becoming rich cinnamon-buff to tawny-buff on centre of belly and undertail-coverts; iris dark brown; bill black; legs grey. Female is similar to male, but head to chest uniformly shining opalescent green, without bluish tinge. Juvenile is mostly dull dark greyish-brown, some weak buff spotting on broad eyebrow, has wings and tail dusky brown, median coverts tipped dull buff, flight-feathers and tertials narrowly edged pale blue, tail feathers dusky with obscure blue-green edgings, feathers of underparts buff, tipped dull dusky brown (imparting freckled and finely spotted appearance), central part of lower breast and belly more extensively buff, undertail-coverts plain dull brownish-buff; immature gradually acquires shining plumage of adult. Race *chaupensis* differs from nominate in having much more opalescent green (less opalescent blue) on foreneck and lesser wing-coverts. Voice. Calls include coarse "jitt", squeaky "eeek", and lower-pitched "chup", sometimes doubled or given in longer series, and thin "sip" notes; rapid ticking twitter in flight. Apparently no song described; some of above-mentioned vocalizations may comprise song.

Habitat. Humid-forest edge, second growth and bushy overgrown pastures and clearings; less often in canopy of humid forest. At 1300–2400 m (to 900 m on Pacific slope) in Colombia; mainly 900–2000 m in Ecuador; 1350–2200 m in Peru. One report from as high as 2750 m.

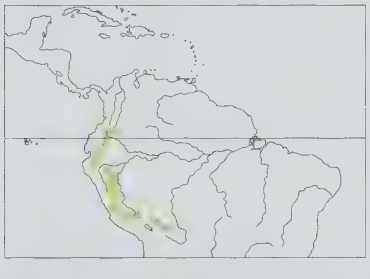
Food and Feeding. Fruits and arthropods. In study in Valle del Cauca, in Colombia, 68% of observed instances of foraging involved insect-seeking. Recorded fruit items include *Miconia* berries and *Cecropia* catkins. Occurs in pairs or in small groups of 3–5 individuals, often with mixed-species flocks along forest borders, especially if other members of its genus present. In Valle del Cauca, median foraging height was 9 m (59 observations), but on average lower for fruit than for insects. Works actively through smaller branches and peers at outer foliage, much in manner of *T. guttata*. Occasionally checks twigs, and sometimes flutters or hangs downwards acrobatically; rarely peers head down at sides of branches in manner of *T. arthus* and many other congeners. Insects almost entirely gleaned from tops and bottoms of terminal foliage.

Breeding. All details from Colombia: one nest in Jul and stub-tailed juveniles seen in Jun, Aug and Nov in Valle; juveniles with adults in Jul in Cundinamarca and Huila and in Aug and Oct in Cauca; 14 birds in breeding condition in Mar–Jul in W Andes and N end of C Andes. No other information.

Movements. Apparently resident.

Status and Conservation. Not globally threatened. Rare to locally fairly common. More numerous in Colombia than elsewhere. Occurs in a number of protected areas, including Farallones de Cali and Cueva de los Guacharos National Parks and Río Blanco de Manizales, Reinita Cielo Azul, Tambito and probably El Pangan Nature Reserves (Colombia), Podocarpus National Park (Ecuador), and possibly one or more parks in N Peru. Although the bulk of this species' range lies in Colombia, where deforestation has been extensive, it does utilize second growth and forest borders, and is not believed to be at risk in the immediate future.

Bibliography. Burns & Naoki (2004), Donegan & Dávalos (1999), Dunning (1982), Fjeldså & Krabbe (1990), Hilty (2009a), Hilty & Brown (1986), Isler & Isler (1999), Lysinger *et al.* (2005), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Miller (1963), Moore *et al.* (1999), Naoki (2003c, 2007), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010), Spencer (2008a), Willis (1966a), Zimmer (1943b).



139. Blue-browed Tanager

Tangara cyanotis

French: Calliste à sourcils bleus **German**: Silberbrauentangare **Spanish**: Tangara Cejiazul
Other common names: Black-cheeked Tanager (*lutleyi*)

Taxonomy. *Calliste cyanotis* P. L. Sclater, 1858, no locality = Peru–Bolivia border region, possibly La Paz (Bolivia).
Two subspecies recognized.

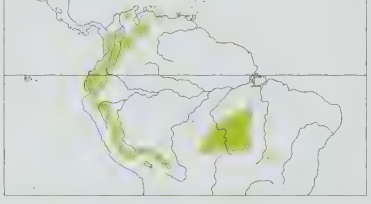
Subspecies and Distribution.
T. c. lutleyi Hellmayr, 1917 – S Colombia (head of Magdalena Valley in Huila, and E slope of Andes from W Putumayo) S through Ecuador and Peru (to Cuzco).
T. c. cyanotis (P. L. Sclater, 1858) – Bolivia (E slope of Andes in La Paz and Cochabamba).

Descriptive notes. 12 cm; 12·5–17 g. Scarce tanager with conspicuous bluish eyebrow. Nominate race has crown blackish, bordered by broad pale cream to greenish-blue supercilium extending from above lores back to side of nape; broad mask from bill and chin rearwards to area around eye, separated from black rear ear-coverts by blue patch on anterior ear-coverts; mantle and back dusky greenish-blue, rump shining silvery bluish to silvery green, becoming darker medium blue on uppertail-coverts; scapulars black, lesser and median upperwing-coverts opalescent blue to pale chartreuse-yellow, greater coverts black narrowly edged and broadly tipped greenish-blue; primary coverts, flight-feathers, tertials and tail black, the feathers of each narrowly edged greenish-blue; throat to middle of breast, also sides and flanks, cream to light blue, slightly tinged greenish, centre of lower breast and belly pale cinnamon-buff, undertail-coverts tinged richer yellow, flanks sometimes slightly mottled with black; iris dark brown; bill black; legs dark grey. Sexes similar. Juvenile like adult but much duller; initially may show little or no blue in plumage. Race *lutleyi* differs from nominate in having side of head black, including rear cheek and ear-coverts, and upper back black (not dusky). Voice. Dawn song a spirited and rather distinctly three-part "tsip'sit'ch't'"t't' zuit-zuit-zuit- zuit, ti, ti, ti, ti", the first phrase complex, middle one lower and slower. Calls rather hard, sharp "tsik" notes resembling those of many others of genus, especially *T. arthus*.

Habitat. Humid and wet montane forest and forest borders, also older second growth. Mostly 1300–2200 m, but reported to 2600 m; 1400–1900 m in Ecuador and 900–1950 m in Peru.

Food and Feeding. Fruits and arthropods. Nineteen stomachs all contained vegetable matter, including fruit pulp and seeds. Forages singly and in pairs, occasionally in family parties of three individuals, regularly with mixed-species flocks containing others of genus; also sometimes independent of mixed-species flocks. In Bolivia foraging heights were at 3–24 m, in crowns of shrubs and trees; for 16 observations, median height c. 7 m and median distance to canopy top c. 1·5 m. Versatile foraging behaviour includes perching upright, occasionally hanging downwards, taking insects from branches and leaf tops, and perhaps most often employing lean-down behaviour to obtain prey from sides of branches and from moss. In Peru searched for insects mostly in canopy,

On following pages: 140. Blue-necked Tanager (*Tangara cyanicollis*); 141. Golden-hooded Tanager (*Tangara larvata*); 142. Masked Tanager (*Tangara nigrocincta*); 143. Beryl-spangled Tanager (*Tangara nigroviridis*); 144. Spangle-cheeked Tanager (*Tangara dowii*); 145. Green-naped Tanager (*Tangara fucosa*).



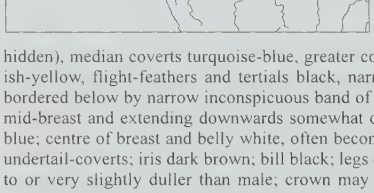
took fruit from melastome shrubs, and mostly examined sides and undersides of bare or sparsely moss-covered branches (mean 1·4 cm in diameter) by using lean-down method on first one side of branch and then other side. Also gleaned prey from undersides of small leaves.
Breeding. Juvenile with adult in Nov, in C Peru (Junín).
Movements. No information.
Status and Conservation. Not globally threatened. Rare to uncommon over most of range; very locally fairly common in Ecuador, and may be more numerous in S portion of range. Regarded as fairly common above San Rafael Falls, in Ecuador. Occurs in a few protected areas, including Tingo Maria National Park (Peru), and possibly Cayambe-Coca Ecological Reserve and Sangay and Podocarpus National Parks (Ecuador). Deforestation an important threat within narrow elevational limits of this low-density species. Its range does, however, include sufficient intact habitat to ensure its survival in at least the immediate future.
Bibliography. Burns & Naoki (2004), Clements & Shany (2001), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Isler & Isler (1999), Lysinger *et al.* (2005), Mee *et al.* (2002), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sedano & Burns (2010), Taczanowski (1884), Zimmer (1943b).

140. Blue-necked Tanager

Tangara cyanicollis

French: Calliste à cou bleu **German**: Azurkopftangare **Spanish**: Tangara Cabeciazul

Taxonomy. *A.[glaia] cyanicollis* d'Orbigny and Lafresnaye, 1837, Yuracares, Bolivia.
Molecular-genetic data indicate that this species is most closely related to *T. larvata*, which is sister-species to both present species and *T. nigrocincta*. Taxonomic status of isolated lowland races *melanogaster* and *albotibialis* may be worthy of investigation. Seven subspecies currently recognized.
Subspecies and Distribution.
T. c. hannahiae (Cassin, 1864) – N Colombia (Sierra de Perijá and N end of E Andes in Norte de Santander) and mountains of Venezuela (Andes from S Lara S to Táchira, Sierra de Aroa, in Yaracuy, coastal cordillera in Carabobo and Aragua, and interior cordillera in N Guárico).
T. c. granadensis (Berlepsch, 1884) – Andes of Colombia (W range S to Munchique area of Cauca, C range and W slope of E range from Santander S to NW Cundinamarca).
T. c. caeruleocephala (Swainson, 1838) – Colombia (head of Magdalena Valley in Huila, and E Andes in Boyacá and Cundinamarca and, on E slope, S to Nariño) S on E slope to N Peru (S to La Libertad and, Huallaga Valley, in N San Martín).
T. c. cyanopygia (Berlepsch & Taczanowski, 1884) – entire W slope of Andes in Ecuador.
T. c. cyanicollis (d'Orbigny & Lafresnaye, 1837) – E slope of Andes in Peru (from Huánuco) S to Bolivia (to Cochabamba).
T. c. melanogaster Cherrie & Reichenberger, 1923 – isolated population in lowlands of Amazon drainage in C Brazil (N Mato Grosso and S Pará); recorded also in C Bolivia (Santa Cruz).
T. c. albotibialis Traylor, 1950 – Veadeiros (Goiás), in EC Brazil.



Descriptive notes. 12 cm; 14–18·8 g. Stunning little tanager with blue head and burnished-gold shoulders. Nominate race has entire head and throat turquoise-blue with black lores and ocular ring; mantle black, becoming turquoise on lower back, opalescent yellow on rump and tinged greenish opalescent on uppertail-coverts; tail blackish, edged yellowish-green; upperwing-coverts opalescent yellow, flight-feathers black, primaries only narrowly and obscurely edged greenish-blue (look blackish), secondaries edged blue, tertials more broadly edged bluish-green or often golden-green; blackish below, flanks and belly violet-blue mixed with black, undertail-coverts black with bluish-green scaling; iris dark brown; bill black; legs dark greyish-horn. Sexes similar, but female tends to have head paler blue, with more visible black feather bases on crown and nape. Juvenile is dull, undistinguished and almost without markings, largely dull grey to sooty grey above and paler buffy grey below, head usually slightly paler, shoulders and wing-coverts buff, secondaries edged greenish, tail sooty with faint bluish edges; older individuals may show some blue flecking on head, as well as pale greenish edgings on wing-coverts and flight-feathers, and dull greenish-tinged rump; immature has darker grey head with blue showing, back dull black, underparts with black mottling, wings sooty black with greenish feather edgings. Race *caeruleocephala* is much like nominate, but throat deep violaceous blue, anterior border of forecrown usually violaceous blue, also rump opalescent yellow; *melanogaster* has belly all black (not mixed with dark blue); *hannahiae* is similar to previous, but with more greenish tinge on shoulder, wing-coverts and rump; *cyanopygia* differs from nominate in having only median wing-coverts burnished opalescent yellow, with greater coverts dusky, edged blue-green, scapulars fringed turquoise-blue, rump and uppertail-coverts, as well as flanks and belly, shining dark opalescent blue; *granadensis* differs in strongly opalescent-green rump and uppertail-coverts, greater coverts tinged greenish or bluish-green, outer primaries very obscurely edged opalescent green, inner primaries edged bluish, secondaries edged opalescent green, and tertials prominently edged opalescent bluish-green (overall wing-coverts greener than on nominate), belly bluer; *albotibialis* resembles nominate, but with paler belly. Voice. Calls include rather low-pitched, penetrating "tzup" notes; also higher "tsip'tsip" and "seep" and lisping, slightly disyllabic "sibit"; also rapid chattery streams of "ti" or "tic" notes, especially when birds excited or about to fly. Presumed song a rapid series of chittery notes followed by several strained, rising notes, e.g. "chit-t-t't't't't't't't', suezzz, suezzz, suezzz".
Habitat. Borders of humid forest, second growth, and overgrown pastures and clearings with scattered trees and shrubs, even in isolated trees; rarely in canopy of mature forest, although does travel across top of forest canopy and is sometimes seen at small openings inside forest. Brazilian race *melanogaster* occurs in drier habitats than others, in palm groves, gallery-forest borders, dry forest and scrub. At 300–2400 m, mostly above c. 500 m, in Andes; isolated C Brazilian population in lowlands at c. 200–500 m.
Food and Feeding. Fruits and arthropods. In Colombia study, fruit comprised 86% of all foraging records, insects 13% and flower buds 1%; recorded as eating at least 24 species of fruit, *Miconia* species comprising 51% of all fruit consumed and *Cecropia* catkins 19%. Of ten stomachs examined, nine contained only vegetable matter and one contained both vegetable and animal matter; items included fruit, berries, seeds and insects. Most often seen in pairs or in small family groups; not regularly with mixed-species flocks, although occasionally around them for short periods of time along forest borders; regularly joins congeners and other species at fruiting trees. In W Colombia forages mostly at middle heights or lower, especially in top of bushes and small trees; median foraging height c. 8 m, infrequently more than 15 m (6% of records). Takes fruit from upright and perched positions, less often when hanging head down for items harder to reach. Most insects captured in short fluttery sallies to air (ten observations) and to leaves (three observations); observed also to search flowerheads and fruiting stalk of a palm. In Peru, foraged in canopy foliage and on bare limbs, two seen on lichen-covered branches but none on mossy limbs.
Breeding. In Colombia, six breeding records Jan–Aug (including two nests in Feb) and seven birds in breeding condition in Jun–Aug. A mossy cup-nest found at moderate height in tree in clearing. One clutch contained 2 eggs. In captivity, 2 eggs, white with brown spots; incubation period 15 days; fledglings independent within three weeks. No other information.
Movements. Presumed resident.
Status and Conservation. Not globally threatened. Widespread, and common to locally common. Brazilian race *albotibialis* known only from one site (Veadeiros, in Goiás). Occurs in numerous protected areas, among them Henri Pittier and Yacambú National Parks (Venezuela), Farallones de Cali and Cueva de los Guácharos National Parks, Arrierito Antioqueña Reserve, Reinita Cielo Azul Natural Reserve, Halcón Colorado Bird Reserve and Tambito Nature Reserve (all in Colombia), Cayambe-Coca Ecological Reserve (Ecuador), Tingo Maria and Manu National Parks (Peru) and Madidi National Park (Bolivia). The species' range also includes much suitable habitat that, although unprotected, is at little immediate risk, and it is further advantaged by the fact that it uses primarily edge habitats and variety of disturbed and regrowth habitats.

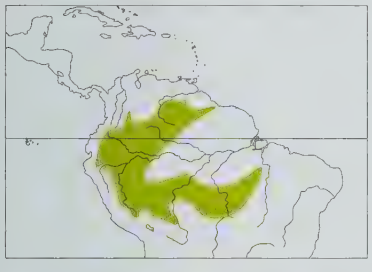
141. Golden-hooded Tanager

Tangara larvata

French: Calliste à coiffe d'or **German**: Purpurmaskentangare **Spanish**: Tangara Cabecidorada
Other common names: Golden-headed/Golden-masked Tanager, Hooded Tanager(!)

Taxonomy. *Calliste larvata* du Bus de Gisignies, 1846, Tabasco, Mexico.
Molecular-genetic data indicate that this species is sister-species to both *T. cyanicollis* and *T. nigrocincta*, and that it is more closely related to former, although it has been treated as conspecific with latter. Geographical variation partly clinal. Four subspecies recognized.
Subspecies and Distribution.
T. l. larvata (du Bus de Gisignies, 1846) – Caribbean slope of SE Mexico (from Tabasco, N Oaxaca and N Chiapas), Belize and E Guatemala S to extreme N Costa Rica.
T. l. centralis (Berlepsch, 1912) – Caribbean slope of Costa Rica and W Panama (Bocas del Toro, N Veraguas and N Coclé).
T. l. franciscae (P. L. Sclater, 1856) – Pacific slope of Costa Rica and W Panama (E to Veraguas).
T. l. fanny (Lafresnaye, 1847) – E Panama (from Colón on Caribbean slope, and from Canal Zone on Pacific slope) E to Colombia (N base of W & C Andes, lower Cauca Valley, middle Magdalena Valley, and Pacific lowlands and slope from Chocó) S to W Ecuador (Manabí and Los Ríos).

Descriptive notes. 12 cm; 17·1–23·9 g. Small, colourful tanager with white belly. Male nominate race has most of head cream to deep golden, turning to rufous on throat; black lores and orbital ring form small mask reaching down onto chin; forecrown violet-blue, this colour extending as smudge of violet-blue surrounding mask and becoming deep blue on cheek; mantle and back black, lower back, rump and uppertail-coverts turquoise-blue, longer uppertail-coverts black, edged light blue; tail black, feathers narrowly edged greenish-blue; shoulder (bend of wing) and lesser upperwing-coverts violet-blue (usually hidden), median coverts turquoise-blue, greater coverts black, prominently edged green to greenish-yellow, flight-feathers and tertials black, narrowly edged pale green; deep rufous of throat bordered below by narrow inconspicuous band of turquoise, and broad black band across chest to mid-breast and extending downwards somewhat onto side of body, rest of sides and flanks deep blue; centre of breast and belly white, often becoming tinged with yellowish to buff on thigh and undertail-coverts; iris dark brown; bill black; legs dusky neutral grey. Female is essentially similar to or very slightly duller than male; crown may show dusky flecking, and white of underparts slightly more extensive. Juvenile is very dull and featureless, above mostly smoky green to grey with greenish tinge, below dingy whitish, throat sometimes tinged with yellow, sides and flanks greyish-buff to olive. Race *centralis* differs from nominate in having cheek, except posterior border, deep blue; *franciscae* is very like previous, but violet-blue of cheek paler; *fanny* differs from nominate in having back of crown, hindneck and throat paler, similar to last in cheek colour, but with pale edging on primaries and wing-coverts reduced or absent, and flanks turquoise (not deep blue). Voice. Calls include high, sharp "tsit" and "chik" notes with hard metallic or gravelly quality, much like those of *T. nigrocincta*; these notes often given in bursts of ticking notes or in accelerating trills and twitters. At dawn a rapid series of dry "tick" notes repeated for a few seconds or up to several minutes, appears to comprise song.
Habitat. Inhabits humid-forest borders, second growth of various ages, and clearings and pastures with scattered trees and shrubs; primarily an edge species in forested regions, occasionally in top of canopy of tall humid forest. Lowlands up to c. 750 m from Mexico to Nicaragua; up to 1200 m, to occasionally 1500 m, in Costa Rica and Panama; up to 1100 m, occasionally 1800 m, in Colombia.
Food and Feeding. Fruits and arthropods. In W Colombia study, fruit accounted for 68% of 180 foraging observations; more than 19 species of fruit eaten, and 62% of all fruit taken were of melastome species, while other important fruit in diet included 13% *Cecropia* catkins, and 10% figs (*Ficus*); seen also to peck at flowers and possibly to eat petals (or immature ovaries). Other fruit items included five species of arillate fruit in Costa Rica and mistletoes berries (Loranthaceae) in Panama. Contents of a single stomach seeds and plant matter. Occurs mainly in scattered pairs or small family parties foraging alone in Colombia, although reported in groups in Costa Rica; infrequently or only transitory in mixed-species flocks along wooded borders, but regularly joins feeding assemblages at fruiting trees. Mostly at middle levels or higher, but may descend as low as eye level to small fruiting shrubs. In W Colombia foraged lower for fruit than for insects, on average



13·7 m up; 12% of all recorded foraging attempts were below 3 m. Single individuals or pairs often sit in treetops, where flutter in foliage or sally awkwardly short distances (less than 0·5 m) for flying insects, including termites (Isoptera), or sometimes reach up and snap nearby flying insects without leaving perch, then fly off to distant fruiting tree or shrub to fill up on fruit; 73% of 52 insect-foraging records involved sallying. Takes fruit mostly while perched upright, but seen to hang downwards from some larger fruits to remove pieces, and clung to catkins.
Breeding. Season Mar–Sept in Costa Rica, Feb–Aug in Panama and Jan–May in W Colombia; two, rarely three, broods sometimes attempted in a season. Occasionally (at least in Costa Rica) one or two helpers from earlier brood attend active nest. Compact open cup-nest of fibres, dry leaves, spider webs and black fungal fibres, in Costa Rica placed 1·5–28 m above ground in fork of tree or bush, sometimes near large trunk; nests reported also as placed among stalk of bananas, in dried corn plant, even in old nest of oropendola (*Psarocolius*). Clutch 2 eggs, dull white or pale grey, thickly flecked with brown, especially at large end; incubation by female alone, may be fed irregularly by male, period 13–15 days; chicks fed by both sexes, sometimes accompanied by one or two helpers, nestling period 14–15 days. Success rate: c. 29% of nests produced at least one fledgling.
Movements. Resident. Minor local movements may occur in response to varying fruit availability.
Status and Conservation. Not globally threatened. Fairly common to common. Widespread on Caribbean slope of Middle America and Pacific slope of Colombia and NW Ecuador. In Ecuador, recent records S only to Pichincha. Occurs in numerous parks and reserves throughout its range; tolerates, and may even profit from, moderate forest disturbance. Range has contracted in face of extensive deforestation in lowland Middle America, but this species is unlikely to face any immediate risks.

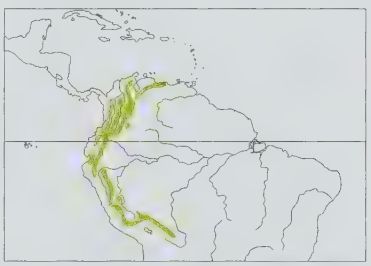
142. Masked Tanager

Tangara nigrocincta

French: Calliste masqué **German**: Schwarzbrusttangare **Spanish**: Tangara Pechinegra
Other common names: Blue-headed/Black-banded Tanager

Taxonomy. *Aglaia nigro-cincta* Bonaparte, 1838, locality uncertain, north-eastern Peru.
Formerly regarded as conspecific with *T. larvata*, but molecular-genetic data indicate that latter is more closely related to *T. cyanicollis* than to present species; *T. larvata* is sister-species to both present species and *T. cyanicollis*. Monotypic.
Distribution. SE Colombia (from Meta and E Vichada) S to E Peru and N & E Bolivia (to NW Santa Cruz) and E to S Venezuela (S of R Orinoco), Guyana and N Brazil (N & W Roraima) and, S of R Amazon, to SC Pará and W Mato Grosso.



Descriptive notes. 12 cm; 15–17·8 g. Small, mostly bluish and black tanager with plumage that looks somewhat faded. Male has head, neck and throat mostly pale lavender-blue, black lores and black ocular ring forming small mask, bluish-green patch on ear-coverts, often extending onto malar area and upper throat; mantle and upper back black, lower back, rump and uppertail-coverts glistening pale turquoise-blue; tail black, faint blue edgings on most of feathers; shoulder (bend of wing) and lesser upperwing-coverts violet-blue (often partially or completely hidden), median coverts edged and broadly tipped greenish to bluish-green, greater coverts blackish, narrowly edged and more broadly tipped bluish-green; primary coverts mostly black (or with faint blue edges), flight-feathers blackish, primaries narrowly edged greenish and secondaries and tertials narrowly edged greenish to bluish-green; broad black band across chest continuing narrowly across lower side of neck to black of mantle; sides and flanks bright blue, centre of breast, belly and undertail-coverts white; iris dark brown; bill black; legs dusky. Female is similar to male, but duller, with breast dusky (not black), and sides and flanks dusky bluish-grey (not black). Juvenile is almost featureless and with little evidence of adult pattern, mainly smoky grey to greyish-olive above, paler below, whitish on median underparts, may have slightly paler head; immature resembles adult but much duller, acquires black first on back (may be mottled) and chest, and has obviously paler head tinged blue. Voice. Calls include bursts of high, staccato ticking notes, also "tsit" or "chit", with hard, gravelly quality; excited birds in E Ecuador emitted a series of "chit" notes accelerating into a chattery trill (possibly song). Song heard infrequently, in SE Venezuela (900 m) a weak complex of jumbled notes followed by a very high-pitched buzzy or sibilant trill, not far-carrying; in Peru described as a high "tseeew-tseeew", similar to double-buzz of song of Pectoral Sparrow (*Arremon taciturnus*) but not so lisping and without introductory "tik" note; song possibly often overlooked, because it is so weak and brief.
Habitat. Humid-forest borders, patches of forest, overgrown clearings with scattered trees and shrubs, and edges of riverine forest; in Amazonian lowlands found also across top of canopy (uses canopy top as horizontal "edge" habitat) in both *várzea* and *terra firme* forest. Lowlands locally to c. 1400 m (most records below c. 600 m) in foothills along base of Andes; to 950 m in Venezuela, 500 m in Colombia, 1000 m in E Ecuador and 1350 m in Peru.
Food and Feeding. Diet mostly fruit (especially small berries) from wide variety of melastomes and other forest-edge species; also arthropods. Five stomachs contained only fruit pulp and seeds. Occurs mainly in pairs or in family groups of 3–4 individuals, which travel and forage alone; associates only infrequently and for short periods of time with mixed-species flocks at forest borders, but readily gathers briefly with congeners and other tanagers and manakins (Pipridae) at fruiting trees. Forages mainly in canopy, occasionally dropping low to feed at fruiting shrubs. Spends relatively little time searching for arthropods, but does often sit on high exposed perches and sallies or flutters short distances upwards after flying insects.
Breeding. Two birds in breeding condition in Jan in NW Brazil. In captivity: built cup-nest; eggs white, heavily spotted brown; incubation by female alone, period 13 days; young fledged in 17 days. No data on breeding in the wild.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon, generally found in small numbers; widespread across W Amazonia. Occurs in Canaima, Duida-Marahuaca, Jaua-Sarisariñama and Yapacana National Parks (Venezuela), Nakuk Natural Reserve and Cahuinarí, Chiribiquete, La Puya and Amacayacu National Parks (Colombia), Cuyabeno Wildlife Reserve, Limoncocha Biological Reserve and Yasuni National Park (Ecuador), Pacaya-Samiria National Reserve and probably Cordillera Azul National Park (Peru) and Serra do Divisor National Park (Brazil). Most of the Venezuelan parks have little protection, but are in largely unpopulated areas. This species is unlikely to face any risks in the near future, being buffered from forest loss, to some extent, by its preference for edge habitat.
Bibliography. Bertagnolio (1968), Burns & Naoki (2004), Dunning (1982), Gilliard (1941), Hellmayr (1910, 1936), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Mee *et al.* (2002), Meyer de Schauensee (1964, 1966, 1970a), Miller (1973), Moore *et al.* (2009), Naoki (2003c), Norgaard-Olesen (1973), O'Neill & Pearson (1974), Phelps & Phelps (1963), Remsen & Traylor (1983), Remsen, Cadena *et al.* (2010), Remsen, Traylor & Parkes (1987), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010), Snethlage (1914), Snyder (1966), Souza (2002), Terborgh & Weske (1969, 1975), Willis (1976a), Zimmer (1943b).

143. Beryl-spangled Tanager

Tangara nigroviridis

French: Calliste béryl **German**: Silberfleckentangare **Spanish**: Tangara de Lentejuelas

Taxonomy. *T.[anagra] nigro viridis* Lafresnaye, 1843, "Bogotá".
Molecular-genetic data indicate that this species, *T. dowii*, *T. fucosa* and *T. vassorii* form a species group, with last-mentioned basal to the other three. Races rather weakly differentiated; *lozanoana*, in particular, seems barely distinguishable from *cyanescens* and should perhaps be synonymized with latter. Proposed race *consobrina* (described from San Pablo, Túquerres, in SW Colombia) is synonymized with *cyanescens*. Four subspecies tentatively recognized.
Subspecies and Distribution.
T. n. cyanescens (P. L. Sclater, 1857) – N & W Colombia (W & C Andes, and W slope of E Andes S from Norte de Santander) and W & SW Ecuador (W slope S to Pichincha; also El Oro and W Loja); also N Venezuela (Sierra de Aroa, in Yaracuy, and coastal cordillera from Carabobo E to Miranda).
T. n. lozanoana Aveledo & Pérez, 1994 – Sierra de Perijá (Colombia–Venezuela border) and Andes of NW Venezuela (S Lara S to Táchira).
T. n. nigroviridis (Lafresnaye, 1843) – E slope of E Andes of Colombia (from Casanare and Boyacá S to Nariño) and entire E slope in Ecuador.
T. n. berlepschi (Taczanowski, 1884) – E slope of Andes in Peru (S from Amazonas) and Bolivia (S to Cochabamba).

Descriptive notes. 12 cm; 14–19·5 g. Small tanager with heavily spotted (spangled) appearance. Nominate race has forehead, chin and lores black, forming rather narrow black mask extending back through and behind eye to a blunt point on nape side; crown and nape shining opal, tinged bluish-green, often some black feather bases showing (especially on rear crown and nape); mantle and back black, rump and uppertail-coverts shining opalescent greenish-blue; tail black, all feathers narrowly edged blue (blue of central pair often obscure); shoulder deep cobalt-blue (usually hidden), lesser upperwing-coverts bright shining medium blue, median coverts tipped shining pale greenish-blue, greater coverts blackish, edged and tipped pale blue to greenish-blue, flight-feathers black, narrowly but sharply edged dark blue, tertials very narrowly edged pale greenish-blue; feathers of side of head broadly tipped pale greenish-blue with black bases, the black often showing prominently and lending spotted appearance to side of head and neck; throat black mixed with shining blue (darker than underparts), breast, belly and undertail-coverts black, heavily spotted opalescent bluish-green; iris dark brown; bill black; legs dark grey to black. Sexes similar. Juvenile is almost entirely dull brownish-grey with dusky wings, back somewhat darker, underparts obscurely mottled and spotted with black; immature and subadult gradually acquire adult plumage but much duller, both usually with dusky to dull blackish rear crown, mantle and back, wings black with at least greater coverts edged and tipped dull bluish (greenish in some races), flight-feathers and tertials narrowly edged blue (to greenish), feathers of rump and uppertail-coverts broadly edged pale opalescent blue (to bluish-green), tail with weak blue-green edging, facial mask as on adult but dusky (not black), side of head and entire underparts mainly dull yellowish-buff, heavily speckled with dusky (feather tips dusky) and with a few pale bluish to greenish spangles showing through on older birds. Race *cyanescens* differs from nominate in bluer upperparts, dull black (not deep cobalt-blue) shoulder, and bluer (less greenish) spangles on underparts; *lozanoana* differs from previous in having wing edgings bluish-green (not dark blue), shoulder deeper black (not dull black), lesser coverts more greenish (less blue), throat lighter blue, underparts slightly brighter greenish, somewhat more spotted on lower underparts; *berlepschi* differs from all others in being darker and more heavily tinged greenish, including on lesser and median wing-coverts and tail. Voice. Calls high-pitched "sit" and "chit" notes or "czee'czet", given in pairs or excited bursts, much as with many others of genus. Song a high, thin "see, sit-sit, see-ee, tzle'tzle'tzeet", weak, easily overlooked, and not heard often.
Habitat. Humid and wet montane forest, along forest borders, second growth and trees in overgrown pastures. At 900–3000 m; most numerous c. 1400–2500 m.
Food and Feeding. Takes wide variety of small fruits and berries, especially of melastomes, i.e. *Miconia*; also some arthropods. Of eight stomachs examined, seven contained only vegetable matter and one only animal matter; contents included fruit pulp, seeds, and beetles (Coleoptera). Of 92 observations of foraging in Valle del Cauca, in Colombia, 85% involved insect-seeking (although this probably overestimates importance of insects in diet). Strikingly social, occurs in pairs when breeding but otherwise usually in small to large groups, occasionally of up to 25 individuals, that forage with, and are often dominant in, mixed-species flocks; also regularly gathers with other small frugivores in fruiting trees and shrubs. Forages from about eye level to high in canopy, more often high, but occasionally even down amid ferns and plants near ground. Forages rapidly, almost running outwards along branches, then pausing for a few seconds to peer with head down, first at one side of branch and then at the other, behaviour similar to that of many congeners. Typically searches small to very small, bare outer branches and twigs, especially those that hang down; occasionally examines moss tufts on twigs, even ends of bare twigs.
Breeding. In Colombia, fledgling in Nov and three birds in breeding condition Mar–Jul in W Valle, and ten birds in breeding condition May–Jul in mountains of N; in Ecuador, nest construction in

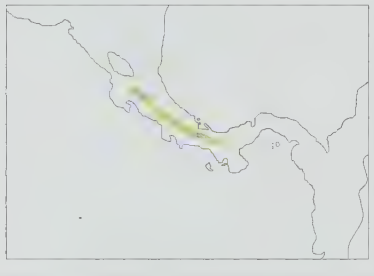
Jun, nestlings Jul and fledglings Sept in NW, and nest-building in SW (Tambo Negro, in Loja) in early Mar. One nest an open cup 10·5 cm wide and 6·5 cm tall, inner cup 5 cm wide and 5 cm deep, made from small fern leaves and rootlets, lined with dead *Chusquea* bamboo leaves and rootlets, placed 6·5 m above ground in moss atop a shaded diagonal branch. No information on clutch size; eggs creamy white or pale green, thickly marked with brown and lilac, especially at large end; no information on duration of incubation and nestling periods; at one nest, chicks fed by both adults, usually arriving more or less together, rate c. 7·2 feeds per nestling per hour, highest in morning (11·6 per hour during first hour), diurnal brooding ceased 6 days before departure from nest, nocturnal brooding may have continued throughout nestling period.

Movements. Largely resident. Minor seasonal or erratic movements to lower elevations reported in W Andes of Colombia, and almost certainly occur elsewhere.

Status and Conservation. Not globally threatened. Generally numerous, and widespread. Occurs in many protected areas, including Henri Pittier, Macarao, Yacambú, Guaramacal, Sierra Nevada and Tamá National Parks and the Palmichal Reserve (Venezuela), Chingaza, Cueva de los Guácharos and Farallones de Cali National Parks and Reinita Cielo Azul, Arrierito Antioqueña, Loro Orejiamarillo, Tambito and Río Blanco de Manizales Nature Reserves (Colombia), Cotocachi-Cayapas Ecological Reserve and Sangay and Podocarpus National Parks (Ecuador), Tingo María and Manu National Parks (Peru) and Madidi National Park (Bolivia). This species' range also includes considerable unprotected but suitable habitat that is at relatively low risk in the foreseeable future.

Bibliography. Álvarez-Rebolledo & Córdoba-Córdoba (2002), Anon. (2000), Aveledo Hostos & Pérez Chinchilla (1994), Best *et al.* (1996), Burns & Naoki (2004), Donegan & Dávalos (1999), Dunning (1982), Fjeldså & Krabbe (1990), Hilty (1997, 2003, 2009a), Hilty & Brown (1986), Isler & Isler (1999), Mee *et al.* (2002), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Miller (1963), Moore *et al.* (1999), Naoki (2007), Ogilvie-Grant (1912), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schäfer & Phelps (1954), Schulenberg *et al.* (2007), Sclater & Salvin (1879), Sedano & Burns (2010), Sheldon & Greeney (2007), Walker (2001), Willis (1966a), Zimmer (1943c).

144. Spangle-cheeked Tanager



Tangara dowii

French: Calliste pailleté **German**: Glanzfleckentangare **Spanish**: Tangara Caripinta

Taxonomy. *Calliste dowii* Salvin, 1863, San José, Costa Rica.

Molecular-genetic data indicate that this species, *T. nigroviridis*, *T. fucosa* and *T. vassorii* form a species group, with last-mentioned basal to the other three. Present species has been considered conspecific with *T. fucosa*, the two being similar in vocalizations, behaviour and habitat preference. Monotypic.

Distribution. Mountains of Costa Rica (from E Guanacaste and S Alajuela) E to W Panama (Chiriquí and Veraguas).

Descriptive notes. 12 cm; 20 g. Small tanager with rather "unkempt", spangled appearance. Male has head to throat and back dull black, with rufous spot on central hindcrown; nape, side of neck, and lower and rear ear-coverts thickly spangled with bluish-green, breast spotted bluish-green, spangles and spotting often more chartreuse-yellow or lime-green, sometimes buffy-white; small central crown spot golden-rufous; rump pale green, uppertail-coverts mixed tawny and light blue; upperwing-coverts, flight-feathers and tail black, feathers edged dark blue; lower breast and belly rich tawny, underwing-coverts buffy white; iris dark brown; bill black; legs dark grey. Female is similar to male, but slightly less spotted on neck and breast. Immature is much duller than adult, spotting less distinct, lacks crown patch. Voice. Calls include high, thin "tsip" or "seek", often accelerating into fast twitter. No song described.

Habitat. Mossy humid and wet forest, forest edges, and second growth and taller trees in clearings adjacent to forest. At 800–3000 m, most numerous at 1200–2750 m.

Food and Feeding. Fruits and insects. Observed to take wide variety of small fruits and berries, including *Gaiadendron* (Loranthaceae), several species of melastome, Ericaceae, *Urera* (Urticaceae) and *Fuchsia* (Onagraceae). Occurs in pairs or small groups throughout year, and often with small mixed-species flocks containing *Chlorospingus* species and other mostly fruit-eating birds. Forages from low to high, but more often at middle levels or higher. Rapidly works outwards along branches, often pausing to lean head down and examine first one side and then the other of mossy branches for insect prey.

Breeding. Breeding reported Apr–Aug in Costa Rica. Nest a bulky cup of green liverworts and mosses mixed with variety of dry fibres, sometimes decorated with pieces of fern, placed amid epiphytes 3·5–10 m up on stump, branch or fork of branch, often at or near forest edge. Clutch 2 eggs, apparently undescribed. No other information.

Movements. Resident. Some minor seasonal elevational movements may occur in response to fruit availability.

Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Fairly common to locally common in Costa Rica; decidedly less numerous and more local in W Panama. Occurs in several parks and other reserves, among them Arenal, Poas, Irazú, Braulio Carrillo and Chirripó/La Amistad National Parks and Monteverde Cloud Forest and Santa Elena Cloud Forest Reserves (Costa Rica) and La Amistad and probably Volcán Barú National Parks (Panama). Vulnerable to deforestation, which has substantially reduced the species' distributional range. At present only relatively small tracts of intact unprotected forest remain (mostly as fragmented patches) within its small range, a problem especially acute in W Panama.

Bibliography. Anon. (1998), Blake (1956), Burns & Naoki (2004), Buskirk (1976), Davis (1972), Eisenmann (1955), Garrigues & Dean (2007), Isler & Isler (1999), Powell (1979), Ridgely & Gwynne (1989), Salvin (1870), Sedano & Burns (2010), Slud (1964), Stiles & Hespenheide (1972), Stiles & Skutch (1989), Wetmore *et al.* (1984), Wheelwright *et al.* (1984), Wolf (1976).

145. Green-naped Tanager

Tangara fucosa

French: Calliste à nuque verte **German**: Grünnackentangare **Spanish**: Tangara Nuquiverde

Taxonomy. *Tangara fucosus* Nelson, 1912, Mount Pirre, 5000 feet [c. 1520 m], Panama.

Molecular-genetic data indicate that this species, *T. nigroviridis*, *T. dowii* and *T. vassorii* form a species group, with last-mentioned basal to the other three. Present species has been considered conspecific with *T. dowii*, the two being similar in vocalizations, behaviour and habitat preference. Monotypic.

Distribution. Mountains of E Panama on Cerro Pirre, the Serranía de Jungurudó, and Cerro Malí (near Cerro Tacarcuna), and Panama–Colombia border on Cerro Tacarcuna; one sight record in NW Colombia on Cerro Tacarcuna (R Tigre).

Descriptive notes. 12 cm; 18–23 g. Small tanager with "unkempt", spangled appearance. Plumage is mainly blackish above, with pale greenish spangles on crown and nape, small bluish-green central crown spot (inconspicuous); greenish rump, becoming light blue on uppertail-coverts; upperwing-coverts dusky, edged blue, flight-feathers dusky, edged paler blue; chin and throat dull black, feathers of foreneck with blue scaling, breast and sides with dull black spots, edged bluish-green to brownish-yellow, rest of underparts cinnamon-buff; iris dark brown; bill black; legs dark grey. Differs from very similar *T. dowii* in overall duller appearance, the blackish areas less intense, bluish-green (not rufous) crown patch, blue scaling on foreneck, black spots extending farther onto sides, and lower underparts paler and duller. Sexes similar. Juvenile undescribed. Voice. Calls high-pitched "tsit" notes and longer "tseet", uttered singly, in combination, or in rapid ticking series; apparently much like (if not identical to) those of *T. dowii*. Song apparently undescribed.

Habitat. Humid pre-montane and montane forest and forest borders. Mostly above 1350 m, but recorded down to 550 m near Cana, in Darién (E Panama).

Food and Feeding. Has been observed to take berries of *Miconia* and an epiphytic vine. Contents of three stomachs were fruit. Reported in groups of 3–4 individuals with mixed-species flocks, especially with *Chlorospingus inornatus*. Seen to forage in crowns of trees in elfin forest, inspecting small leaves and mosses on slender branches.

Breeding. One nest reported in Aug in Serranía de Jungurudó. Nest appeared ball-shaped, was located c. 15 m up between palm-frond leaflets and atop main palm vein; as all known nests of this genus are cup-nests (though sometimes built inside moss clump on side of branch, or suspended in moss beneath branch), further confirmation of nest structure of this species needed. No further information available.

Movements. No information.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Darién Highlands EBA. Fairly common within its extremely limited global range. Occurs in Darién National Park, in Panama. In Colombia, known from a single sight record that may fall within Los Katíos National Park, but status in Colombia uncertain. There is, at present, minimal human impact within its tiny range. Gold-mining at elevations below those at which this species occurs present a potential problem. More importantly, the possible extension and completion of the Pan-American highway link through Darién could be environmentally disastrous for this species because of the deforestation and human settlement that would inevitably follow.

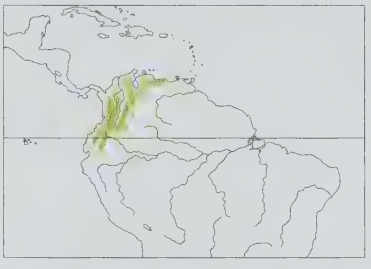
146. Blue-and-black Tanager

Tangara vassorii

French: Calliste bleu et noir **German**: Vassoritangare **Spanish**: Tangara Azulinegra
Other common names: Tamiapampa Tanager (*branickii*); Buff-naped Tanager (*atrocoerulea*)

Taxonomy. *Tanagra* (*Euphone*?) *Vassorii* Boissonneau, 1840, Santa Fé de Bogotá, Colombia.
Molecular-genetic data indicate that this species, *T. nigroviridis*, *T. dowii* and *T. fucosa* form a species group, with present species being basal to the other three. Taxonomic status of the two S races, which differ markedly from nominate N race, may merit investigation. Three subspecies currently recognized.
Subspecies and Distribution.
T. v. vassorii (Boissonneau, 1840) – Andes in Venezuela (Trujillo S to Táchira) and throughout Colombia S to Ecuador and E slope in N Peru (S to Piura and Cajamarca N of R Marañón).
T. v. branickii (Taczanowski, 1882) – E slope of Andes in Peru S of R Marañón (Amazonas and La Libertad).
T. v. atrocoerulea (Tschudi, 1844) – E slope in Peru (S from Huánuco) and Bolivia (S to W Santa Cruz).



Descriptive notes. 13 cm; 15–21 g. Beautiful dark blue high-elevation tanager with rather short bill and relatively short tail. Nominate race is mostly shining deep cobalt-blue; lores, very narrow line over bill and chin black; greater upperwing-coverts black, tipped cobalt-blue (forming single dark blue wingbar), flight-feathers, tertials and tail black, sometimes narrowly edged blue; bases of feathers of body plumage dusky, occasionally showing through as dusky mottling or faint barring (more prominent on younger birds); iris dark brown; bill black; legs greyish-black. Sexes similar. Juvenile is almost entirely grey to brownish-grey with contrasting dusky wings and tail, sometimes faint bluish tinge on mantle and back, bill dusky horn, gradually acquires more bluish in plumage with age; immature dull greyish, usually with blue tinge, and both upperparts and underparts mottled, and variably spotted and barred with dusky blue, upperwing-coverts as on adult but duller, loral area blackish as on adults but duller, wings and tail dull dusky black. Race *branickii* differs from nominate in having crown and side of head dull greenish-blue; *atrocoerulea* differs from nominate in having duller bluish head, conspicuous opalescent-buff patch on hindcrown, solidly black lower mantle and back, and underparts spotted and scaled black. Voice. Calls include high-pitched, thin "tsit" and "chip" notes, none very distinctive, during foraging. Infrequently heard song a notably high, thin "tsiit, tsiit, tsiit, tsiit", forceful but not loud or far-carrying; song in Colombia (Bogotá) a series of sharp notes that rise slightly and end in weak trill, "tseu, tseu, tseu ti'ti'ti'ti'ti'ti'ti'ti'ti".
Habitat. Humid and wet, often mossy montane forest, forest edges, second growth and trees and shrubs in partly cleared highland pastures. At 1800–3200 m (most records above 2000 m) in Venezuela, 1900–3400 m in Colombia, mostly 2000–3300 m (rarely to 3600 m) in Ecuador, and c. 2000–3400 m (once to 1580 m) in Peru; has been recorded as low as 1300 m in Bolivia. No congener regularly occurs at such high elevations; at many high-lying sites the only member of genus present.
Food and Feeding. Fruit; also, in far smaller quantity, arthropods. Of 17 stomachs examined, 14 contained only vegetable matter and three contained both vegetable and animal matter; contents included fruit pulp, seeds, berries, and insects. Other stomachs contained seeds of melastome fruits. Rather social, occurring in pairs or small groups up to about six individuals, infrequently more, and most often in association with highland mixed-species flocks of frugivores and insectivores such as woodpeckers (Picidae), ovenbirds (Furnariidae), *Conirostrum* conebills and mountain-tanagers; readily joins frugivores at fruiting trees and shrubs. Active and usually on the move. Foraging behaviour more variable than that of many congeners. Usually seen at middle levels or higher, hopping and peering in outer foliage and on small outer twigs, mostly for fruit; less often, works quickly outwards along branches, peering head down to inspect first one side and then the other. Also checks various epiphytes, including small bromeliads, and may hang downwards to examine substrates.
Breeding. In Colombia, two nests in Jun and begging juveniles in Jan in W Valle, fledglings in May in E Cauca, and nine birds in breeding condition in Feb–Aug in C & E Andes. Nest an open cup of plant fibres, located 3–6 m above ground near end of branch. Clutch 2 eggs, greenish with dark spots. No other information.
Movements. Generally resident. Some seasonal elevational movements may occur.
Status and Conservation. Not globally threatened. Uncommon to fairly common; seldom numerous. Occurs in a number of protected areas, among them Guaramacal, Sierra Nevada and Tamá National Parks (Venezuela), Chingaza, Cueva de los Guácharos, Las Orquídeas, Farallones de Cali and Puracé National Parks and Tambito, Río Blanco de Manizales and probably El Mirador Nature Reserves (Colombia), Cotocachi-Cayapas and Cayambe-Coca Ecological Reserves and Sangay, Las Cajas and Podocarpus National Parks (Ecuador), Tingo María and Manu National Parks (Peru) and Madidi National Park (Bolivia). Within this species' range substantial intact habitat exists outside protected areas, although deforestation continues to diminish the area available, especially in upper end of its range, where deforestation and firewood-cutting are severe.
Bibliography. Anon. (2000), Burns & Naoki (2004), Carriker (1941–1954), Donegan & Dávalos (1999), Dunning (1982), Fjeldså & Krabbe (1990), Goodfellow (1901), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Krabbe *et al.* (2001), Mazar Barnett *et al.* (2006), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Parker & O'Neill (1980), Phelps & Phelps (1963), Remsen *et al.* (1987), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010), Taczanowski (1884), Terborgh & Weske (1975), Walker (2001), Zimmer (1943c).

147. Black-capped Tanager

Tangara heinei

French: Calliste à calotte noire **German**: Heinetangare **Spanish**: Tangara Coroninegra

Taxonomy. *P.*[*rocnias*] *Heinei* Cabanis, 1851, Colombia.
Molecular-genetic data indicate that this species, *T. phillipsi*, *T. viridicollis* and *T. argyrofenges* form a species group, and that *T. cyanoptera* is sister to this group. Present species and *T. phillipsi* sometimes thought to form a superspecies; has been suggested that the two might be better treated as conspecific, but most authors argue that, because of the wide geographical distance between them, as well as plumage differences, they are best regarded as separate species. Monotypic.
Distribution. Colombia in Santa Marta Mts, all three Andean ranges (including E slope of E Andes), and on W slope in Ecuador, also Sierra de Perijá (Colombia–Venezuela border) and mountains of N Venezuela (including coastal cordillera E to Distrito Federal, interior cordillera in N Guárico, Cerro El Cerrón on Falcón–Zulia–Lara border, and Andes from S Lara S to Táchira).

Descriptive notes. 13 cm; 18–22·8 g. Bluish to greenish tanager, male with black cap. Male has forehead, crown and upper nape to loral area and below eye black, tailing down behind rear ear-coverts; upperparts, including upper-tail-coverts, shining silvery bluish-grey; upperwing-coverts dull bluish-grey, obscurely edged dull blue, primary coverts black with dull blue on outer edges, flight-feathers black, edged dull blue (edging paler than wing-coverts), tertials black with dull blue outer web; throat, side of head to eye, side of neck and chest shining aquamarine-green, feather tips lanceolate, with black bases showing at edges (imparting slightly streaked or scaled appearance); rest of underparts uniformly dull grey-blue, except undertail-coverts, which have blackish centres and broad white margins; iris dark brown; bill and legs black. Female has crown dusky green, each feather with dusky base and weak pale green edges (giving slightly scaled appearance), upperparts shining pale green, tail dull green to olive-green; lesser and median upperwing-coverts mainly greenish with dusky bases, greater coverts dusky with outer half of each feather dull green (wing-coverts look mainly green), primary coverts dusky with dull green on outer edges, flight-feathers dusky, edged blue-green, tertials with dull green outer half of feather; below, similar to male but much duller and greener, with throat, side of neck and chest dull glaucous green with slightly scaled or mottled appearance (due to dusky feather bases), lower breast and belly grey, sides and flanks olivaceous yellow-green, undertail-coverts similar to those of male. Juvenile male is essentially like female, but with pale blue primary edges; immature of both sexes like female but even duller, although usually with pattern of respective adult faintly indicated; subadult male resembles female, but with early stages of adult male plumage, including dull dusky-green crown mixed black, pale green mantle and back mixed silvery blue, greater coverts and secondaries strongly edged green, but flight-feathers edged blue-green, and throat showing shining green feathers mixed dusky and underparts mixed greyish and greenish. Voice. Calls include high, nasal "zheet" and high "tsit", neither especially distinctive. Unlike most congeners, does sing frequently, although song no more likely to be heard at dawn that at various times during day: song, from high and sometimes exposed position, rather low-pitched, remarkably long (up to 10 seconds), mechanical-sounding, and very fast "t'kling-t'kling-t'kling...", not loud but with peculiar ringing quality (as if two birds singing simultaneously), may be repeated a few times in space of a few minutes.
Habitat. Humid and wet forest, forest borders, older second growth, and trees and shrubs in clearings. At 1000–2800 m, most records c. 1500–2200 m; once down to 700 m in Colombia; 1100–1900 m in Ecuador.
Food and Feeding. Generally much fruit, especially melastome berries, in diet; some arthropods. Pairs and family groups wander along forest borders and disturbed areas, more often away from mixed-species flocks than with them; sometimes with other species in fruiting trees. Forages predominantly high up, seldom down to eye level. Inspects branches with stereotyped lean-down movement as it peers at alternate sides of mossy or bare branches; behaviour like that of numerous other members of genus, but movements shallower, briefer, and not likely to be long-sustained. Also hops and peers in outer foliage.
Breeding. In Colombia, nesting activity in Jan, Apr and Aug in Andes and 15 birds in breeding condition in Jan–Sept in N; nest in May in Venezuela; in Ecuador, season probably Jan–Jun, with peak Mar–Apr (rainiest months), in NE and breeding activity reported elsewhere in Dec and Jul. Nest built by both sexes (Colombia) or by female (Ecuador), or male reported as helping to rear-range nest material but not bringing it (Venezuela); nest a grassy cup with moss and lichens on outer surface, in Ecuador outer material lichens (c. 55–65%), pale rootlets (15–25%) and moss (less than 15%), external width c. 9·2 cm, height 7 cm, placed 1·2–8 m above ground (1–3 m in Colombia) and supported by three or more forking stems or *Chusquea* bamboo shoots, anchored with spider web, in second-growth vegetation (e.g. overgrown pasture, road cut). Clutch 1–2 eggs (generally 2), dull blue to pale greenish-white, heavily blotched and spotted reddish-brown; incubation by female alone, occasionally fed on nest by male, female sits for c. 63% of time (average 14·7 minutes per session), incubation period c. 13·5–14 days; chicks brooded only by female, fed by both parents, at one nest male made 53% of food deliveries and directly fed nestlings on 73·4% of occasions, at other times passed food to mate and she then fed chicks, each nestling fed 5·95 times per hour; no information on duration of nestling period. Of seven nests observed, only two produced fledged young.
Movements. Mainly resident. Some seasonal descent to lower elevations (as low as 1000 m) during rainiest months in N Venezuela; similar movements may occur elsewhere.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Usually found in low numbers. Occurs in numerous protected areas, including Henri Pittier, Guaramacal, Sierra Nevada and Tamá National Parks (Venezuela), Sierra Nevada de Santa Marta, Las Orquídeas, Tatamá and Farallones de Cali National Parks and Tambito Nature Reserve and others (Colombia), and possibly Cotocachi-Cayapas Reserve (Ecuador). The species' range also includes some intact habitat that is unprotected, but much has already been lost to deforestation. Ability of this species to utilize middle-age and older second growth buffers it somewhat from long-term risks.
Bibliography. Anon. (2000), Arcos-Torres & Solano-Ugalde (2007), Burns & Naoki (2004), Donegan & Dávalos (1999), Dunning (1982), Ewert (1975), Fjeldså & Krabbe (1990), Freeman & Greeney (2009), Freile (2004), Greeney & Nunnery (2006), Greeney, Freeman *et al.* (2008), Hilty (2003, 2009a), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Miller (1963), Moore *et al.* (1999), Ogilvie-Grant (1912), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Stiles *et al.* (2002), Schäfer & Phelps (1954), Sclater & Salvin (1879), Sedano & Burns (2010), Todd & Carriker (1922), Willis (1966a).

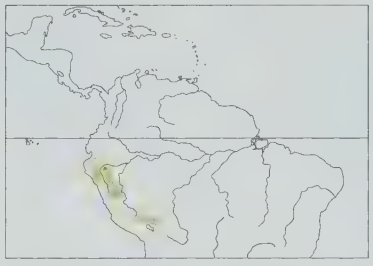
On following pages: 148. Sira Tanager (*Tangara phillipsi*); 149. Silver-backed Tanager (*Tangara viridicollis*); 150. Straw-backed Tanager (*Tangara argyrofenges*); 151. Black-headed Tanager (*Tangara cyanoptera*); 152. Opal-rumped Tanager (*Tangara velia*); 153. Opal-crowned Tanager (*Tangara callophrys*); 154. Swallow Tanager (*Tersina viridis*).

148. Sira Tanager

Tangara phillipsi

French: Calliste de Phillips **German**: Siratangare **Spanish**: Tangara del Sira
Other common names: Siara Tanager

Taxonomy. *Tangara phillipsi* G. R. Graves and Weske, 1987, Cerros del Sira, 1300 m, Huánuco, Peru.
Molecular-genetic data indicate that this species, *T. heinei*, *T. phillipsi*, *T. viridicollis* and *T. argyrofenges* form a species group, and that *T. cyanoptera* is sister to this group. Present species and *T. heinei* sometimes thought to form a superspecies; has been suggested that the two might be better treated as conspecific, but most authors argue that, because of the wide geographical distance between them, as well as plumage differences, they are best regarded as separate species. Monotypic.
Distribution. Cerros del Sira (E of E base of Andes in E Huánuco), in Peru.



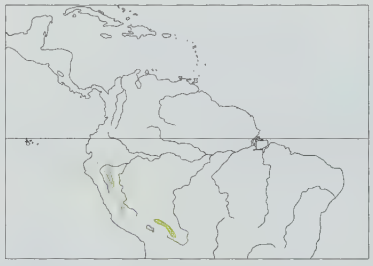
Descriptive notes. 13 cm; 16·8–21·7 g. Male has black crown to hindneck, black extending down behind ear-coverts onto rear side of neck and to chest, enclosing blue-green throat (throat feathers black with glossy, metallic bluish-green tips); lower nape, mantle, back and rump shining opalescent greenish-blue (colour varies with angle of light); tail black, outer feathers edged and tinged greyish-blue; upperwing-coverts and flight-feathers black, edged slate-blue; central area of breast and belly mostly black, with broad area of prominent opalescent blue (this can look green, depending on light) across sides and flanks; undertail-coverts bluish-grey, underwing-coverts white; iris dark brown; bill and legs black. Differs from *T. heinei* in having black of crown connecting to black central lower underparts, and central underparts black, not blue-grey. Female has top of head dusky green (feather bases dusky, with pale green edges); upperparts, including uppertail-coverts, shining pale green, upperwing-coverts mainly greenish with dusky bases, primary coverts dusky, flight-feathers dusky, edged blue-green, tertials dull green with dusky inner webs, tail dull green to olive-green; much duller than male below, has throat, side of neck and chest dull glaucous green with dusky feather bases and paler tips (slightly scaled and mottled appearance), breast, centre of belly and undertail-coverts dull greenish-grey to grey, brighter on sides and flanks, undertail-coverts dull pale greyish-white, tinged green; much like female of *T. heinei*, differing primarily in having breast and belly greyish, and throat feathers less bifurcated and more pointed. Juvenile undescribed. Voice. No information; apparently undescribed.
Habitat. Canopy and edges of tall, mossy, pre-montane wet forest on isolated outlying ridges; 1300–1570 m.
Food and Feeding. Not well known. Mixed diet of fruits and insects, apparently much like that of congeners. Regular member of canopy mixed-species flocks containing other members of genus and other tanagers, and also small frugivores and insectivores; often outnumbers congeners in mixed flocks. Observed in forest at heights of 11–25 m above ground, and commonly 3–10 m up in ridgetop scrub.
Breeding. No information. Birds in Jul were not in breeding condition.
Movements. Resident; some minor seasonal elevational movements possible.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Peruvian East Andean Foothills EBA. Locally fairly common to common. Because of its remote range, this species is believed not to be at any immediate risk; an expedition that visited this area in 2000 found its habitat to be largely untouched. Known global distribution, however, extremely small, estimated breeding range c. 720 km², and gold-mining and copper-mining, as well as small-scale logging operations, have been underway nearby at base of Cerros del Sira for some time. Logging operations possibly increasing along W base of the Sira in R Pachitea.
Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Clements & Shany (2001), Graves & Weske (1987), Mee *et al.* (2002), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Stattersfield & Capper (2000), Vuilleumier *et al.* (1992).

149. Silver-backed Tanager

Tangara viridicollis

French: Calliste argenté **German**: Silbertangare **Spanish**: Tangara Dorsiplateada
Other common names: Silvery(-backed) Tanager; Tambillo Tanager (*fulvigula*)

Taxonomy. *Calliste argentea viridicollis* Taczanowski, 1884, Huiro, 4800 feet [c. 1460 m], Cuzco, Peru.
Molecular-genetic data indicate that this species, *T. heinei*, *T. phillipsi* and *T. argyrofenges* form a species group, and that *T. cyanoptera* is sister to this group. Nominate race apparently intergrades with *fulvigula* in N Peru (vicinity of R Marañon) where examples tend to be intermediate in plumage. Two subspecies recognized.
Subspecies and Distribution.
T. v. fulvigula (Berlepsch & Stolzmann, 1906) – Andes in S Ecuador (W slope in El Oro and W Loja, also old record from Azuay; E slope in extreme S Zamora-Chinchipe) and N Peru (adjacent E slope in S to Lambayeque and Cajamarca, and on both slopes of dry W Andes).
T. v. viridicollis (Taczanowski, 1884) – E slope of Andes of Peru S of R Marañón (Amazonas S, discontinuously, to Puno) and W Bolivia (near Tokoaque, in La Paz).
Descriptive notes. 13 cm; c. 18–24 g. Sexually dimorphic tanager, male unusual in having most of underparts much darker than upperparts. Male nominate race has dark peach-coloured to golden throat and side of head, bordered by black crown and upper nape down to chin and below eye, black continuing narrowly around rear side of neck and forward onto breast and mid-belly; upperparts silvery blue-grey to silvery opal (varying with angle of light); tail black, edged blue-grey; lesser and median upperwing-coverts mostly black, variably edged greenish-blue, greater coverts black, narrowly edged greenish-blue; flight-feathers dusky, edged greenish-blue, tertials mostly dull greenish-blue with dusky inner webs; sides and flanks silvery blue-grey; iris dark brown; bill blackish; legs dark grey. Female has crown dusky brown, faintly tinged green, nape to uppertail-coverts shining light green, throat and side of head glistening straw-yellow with variable coppery sheen, slightly streaked greenish-copper, and becoming mixed dusky and pale aquamarine on chest



and pale green on breast; sides and flanks pale green, tinged yellowish, lower breast and median underparts dingy ash-grey with hint of greenish. Juveniles is extremely dull and dingy, and almost devoid of strong colour or pattern; immature resembles adult, but duller. Race *fulvigula* male is paler than nominate, back more silvery opaline to silvery green (depending upon light), and throat darker, female has more golden-brown crown and brighter, more copper-coloured throat than nominate. Voice. Weak "chit" and "tsit" notes, much like those of congeners but perhaps slightly more husky; also high wheezy, descending "tseer" and thin "pit". Song, in Peru, described as a series of rapid descending notes. True song heard only infrequently.
Habitat. Borders of humid and wet forest, woodlots, remnant forest patches and heavily cut-over second growth; in NW Peru occurs in fairly dry scrub (where may be the only member of genus present) and degraded habitats, including overgrown pastures, dry scrubby hillsides, and landslide regrowth. At 1450–3050 m; most common in lower third of this belt, at c. 1500–2000 m.
Food and Feeding. Of four stomachs examined, one contained only vegetable matter and one only animal matter and two contained both fruit and arthropods. Seen to feed on *Miconia* berries near Machu Picchu (S Peru), and regularly takes nectar (or possibly immature flower ovaries) from *Inga* flowers, often moving steadily from one to the other. Occurs mainly in pairs, less often in small family groups of 3–5 individuals, foraging alone or with mixed-species flocks contain other members of genus and other small frugivores; often gathers with other birds at fruiting trees and shrubs. Found from about eye level to canopy of tall trees, mostly at middle levels or higher. Foraging behaviour recalls that of *T. heinei*. Examines small (diameter less than 12 mm), mostly bare twigs within canopy by hopping from one to another, pausing to lean forwards and downwards to inspect sides of twigs; may spend considerable time insect-hunting in this manner.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common; generally occurs in low numbers. Present in Machu Picchu World Heritage Site and probably Cordillera de Colán and Tingo Maria National Parks, in Peru. Fairly common resident in Machu Picchu Pueblo Hotel grounds (outside Aguas Calientes), at a site that is heavily modified and includes second growth and horticultural plantings; fairly common locally in dry-scrub hillside habitat in the Piura and Cajamarca region, e.g. Abra de Porculla, in NW Peru. Because this species occurs mainly in, or is more easily seen in, forest fragments, second growth and dry scrub, rather than in undisturbed forest, it is protected somewhat from the risks of deforestation and human settlement.
Bibliography. Burns & Naoki (2004), Clements & Shany (2001), Coopmans *et al.* (2004), Fjeldså & Krabbe (1990), Hennessey & Gomez (2003), Hilty (2009a), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Rasmussen *et al.* (1996), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sibley & Monroe (1990), Taczanowski (1884), Walker (2001), Zimmer (1943c).

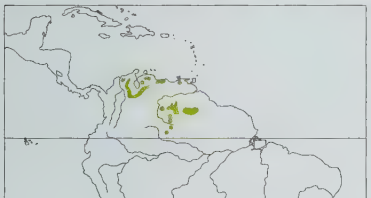
150. Straw-backed Tanager

Tangara argyrofenges

French: Calliste à gorge verte **German**: Grünkehltangare **Spanish**: Tangara Dorsipajiza
Other common names: Green-throated Tanager

Taxonomy. *Calliste argyrofenges* P. L. Sclater and Salvin, 1876, Yungas, La Paz, Bolivia.
Molecular-genetic data indicate that this species, *T. heinei*, *T. phillipsi* and *T. viridicollis* form a species group, and that *T. cyanoptera* is sister to this group. Sympatric with very similar *T. viridicollis* at Panguri, in S Ecuador. Most of the characters ascribed to race *caeruleigularis* appear to have little or no value, and species may be better treated as monotypic. Two subspecies tentatively recognized.
Subspecies and Distribution.
T. a. caeruleigularis Carriker, 1935 – extreme SE Ecuador (S Zamora-Chinchipe) and N & C Peru (E slope of Andes in Amazonas and San Martín, also a few scattered records Junín and Pasco).
T. a. argyrofenges (P. L. Sclater & Salvin, 1876) – E slope of Andes in Bolivia (La Paz, Cochabamba and W Santa Cruz).

Descriptive notes. 13 cm; 18–20 g. Male nominate race has throat, side of head and throat to foreneck shiny pale aquamarine to opalescent green, enclosed by black on rest of head to upper nape and wrapping narrowly around on rear side of neck and down to black breast, belly and undertail-coverts; upperparts, including most of uppertail-coverts, shining pale yellow-buff, longest uppertail-coverts black; tail and entire upperwing and its coverts jet-black; sides and flanks yellow-buff, like back; iris brown; bill black; legs dark grey. Female has throat, side of head and chest dull opalescent green, as on male but considerably duller; crown and nape dusky, mixed greenish, back and rump dull straw-yellow, tinged green, uppertail-coverts more strongly greenish-tinged, wing and tail blackish, feathers edged pale green; breast and lower underparts mostly grey to greenish-grey with yellow tinge, sides and flanks yellowish-green. Juvenile undescribed. Race *caeruleigularis* is very similar to nominate, male differing in having the yellowish feathers rather paler straw-yellow, and throat slightly bluer. Voice. Song, in Peru, described as a high, wheezy series of lisping notes and a long, even, *Chlorophonia*-like "weee". Calls include high, descending "tsew" and dry "tip".
Habitat. Humid montane forest and forest borders, less often in adjacent mature second growth. At 1350–1600 m in Ecuador and 1100–2200 m in Peru; 1200–2700 m, most numerous at 1600–1900 m, in Bolivia.
Food and Feeding. Fruit and insects; noted as eating *Cecropia* catkins. One stomach contained small berries. Pairs forage with mixed-species flocks, especially those containing other members of genus, and occasionally occur in same mixed flocks as does *T. viridicollis* (in N Peru). Forages mostly at middle levels or higher in trees, generally staying well hidden. Inspects leaves, bark and slender branches.



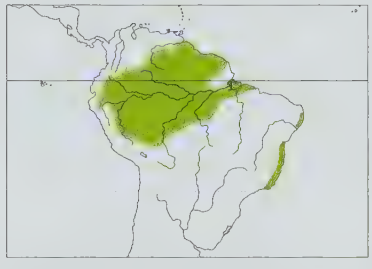
Breeding. No information.
Movements. No information.
Status and Conservation. Not globally threatened. Restricted-range species: present in Ecuador-Peru East Andes EBA, Peruvian East Andean Foothills EBA and Bolivian and Peruvian Lower Yungas EBA. Rare in Ecuador; uncommon and local in Peru. Throughout range found in small numbers. S population probably occurs in Madidi National Park, possibly also Isiboro Sécure and Amboró National Parks, in Bolivia; N population may occur in or near Podocarpus National Park, in Ecuador, and Cordillera de Colán in Amazonas, in Peru. Little information exists on the current status of any population of this species.
Bibliography. Burns & Naoki (2004), Clements & Shany (2001), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Niethammer (1956), Parker *et al.* (1982), Rasmussen *et al.* (1996), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Sedano & Burns (2010), Taczanowski (1884), Zimmer (1943c).

151. Black-headed Tanager

Tangara cyanoptera

French: Calliste à tête noire **German**: Blauflügeltangare **Spanish**: Tangara Cabecinegra
Other common names: Whitely's Tanager (*whitelyi*)

Taxonomy. *A.*[*glaia*] *cyanoptera* Swainson, 1834, no locality = Caracas, Venezuela.
Molecular-genetic data indicate that this species is sister to a species group formed by *T. heinei*, *T. phillipsi*, *T. viridicollis* and *T. argyrofenges*. Races are geographically isolated from each other and differ somewhat in plumage and habitat; possible separate species status merits investigation. Two subspecies currently recognized.
Subspecies and Distribution.
T. c. cyanoptera (Swainson, 1834) – N Colombia (Santa Marta Mts, and both slopes of E Andes at N end), Sierra de Perijá, and W & N Venezuela (Andes from Lara S to Táchira, mountains of C Falcón and Yaracuy, and N cordilleras from Carabobo E to Sucre and Monagas).
T. c. whitelyi (Salvin & Godman, 1884) – tepuis of S Venezuela (in Amazonas and Bolívar), and adjacent N Brazil (Uei-tepui) and Guyana (Twek-quay).



Descriptive notes. 13 cm, one female 18 g (nominate); 14 cm, 21·5–24·5 g (*whitelyi*); male 17·1–24·5 g and female 18–27·5 g (Venezuela, race unspecified). Male nominate race has head to upper nape and throat black, with narrow white feathering on lores, submoustachial area and chin, rest of plumage shining yellowish to greenish opal (depending on light), usually faint dusky mottling on chest; mantle generally more yellowish opal, rump faintly tinged with green, may show variable amount of blackish mottling (or none) on back and rump; upperwing-coverts black, greater coverts prominently edged blue, flight-feathers and rectrices blackish, narrowly edged bright blue; iris deep brown; bill blackish; legs dark grey. Female is very different from male, has crown and side of head greyish-green, fading to light greenish-yellow on lower mantle and rump, duller and darker olivaceous-green on uppertail-coverts, primary coverts dusky with narrow dull green edges, rest of upperwing-coverts dusky with broad and diffuse dull green edges, flight-feathers and rectrices dusky with blue-green edges, more olivaceous-green and broader on outer web of tertials; throat to mid-breast dingy greyish-white with obscure dusky streaking, lower underparts pale yellow, brightest yellow on centre of belly, greener on flanks, undertail-coverts dull olive. Juvenile is brownish-grey above, wing-coverts pale-edged, underparts dingy whitish with hint of diffuse streaking; immature male similar to adult but duller, with more dusky mottling and flecking above and below. Race *whitelyi* male differs from nominate in overall dark yellowish-opal coloration, underparts more obviously and extensively mottled with black, wing uniformly black with no blue edgings, female differs from nominate in having upperparts duller and darker, underparts with more ashy spotting. Voice. Variety of very high-pitched, buzzy and lisping notes, e.g. "djeet", during foraging, but otherwise not very vocal. Song (nominate race), seemingly given only infrequently, an extremely high-pitched "weeu-weeu-weeu-weeu", 3–5 notes, weak and easily overlooked. Another vocalization described as a quavering squeal lasting 1–2 seconds, repeated at intervals.
Habitat. Nominate race occurs in moist to moderately humid woodland, mainly along borders, scattered trees in clearings, shade trees in coffee plantations and lightly wooded areas. S race *whitelyi* in mossy, humid and wet forest borders, and especially stunted melastome-dominated second growth. At 600–2000 m in N Colombia; in Venezuela, 450–2200 m (mostly above 800 m) N of R Orinoco, and 1100–2250 m S of R Orinoco (on tepuis).
Food and Feeding. Variety of small fruits, e.g. recorded as taking melastome berries and *Cecropia* catkins; some arthropods. Usually seen singly or in pairs or families, seldom in groups of more than 3–5 individuals; associates with mixed-species flocks and forages independently of them about equally, and regularly gathers with other small frugivores at fruiting trees. Generally forages in canopy or remains fairly high; seldom descends low to fruiting shrubs. Foraging behaviour less structured (stereotyped) than that of many members of genus, and includes hopping and peering in outer foliage, and occasionally making short sallies or flutters for flying insects; may work outwards and peer, head downwards, at sides of branches, alternately on one side and then on other, but movements shallow and less persistent than those of many congeners. Race *whitelyi* may employ lean-down foraging motions more frequently than nominate. In moist park-like areas, nominate race frequently checks tufts of *Usnea* lichen on high branches, but seems not to dedicate much effort to searching for arthropods.
Breeding. Nine birds in breeding condition in Mar–Jun in N Colombia. Eggs white, marked with shades of brown and grey. No other information.
Movements. Predominantly resident. Some local movements, especially within drier habitats favoured by nominate race, seem likely.
Status and Conservation. Not globally threatened. Fairly common locally. Utilizes disturbed woodland, woodlots, small forest fragments, coffee plantations, and borders of more mature forest, which buffers this species, to some extent, from effects of deforestation. Occurs in, among others, Canaima, Henri Pittier, Guatopo, Yacambú, Terepaima, Dinira and Sierra Nevada National Parks (Venezuela); probably also in Perijá National Park (also Venezuela), although this does not receive significant protection. This species' range includes considerable suitable habitat that is not protected, but appears unlikely to face serious risks in the near future.
Bibliography. Ascanio (2009), Burns & Naoki (2004), Dunning (1982), Gilliard (1941, 1959), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Nehrkorn (1899), Ogilvie-Grant (1912), Phelps & Phelps (1963), Remsen *et al.* (2010), Restall *et al.* (2006), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schäfer & Phelps (1954), Sedano & Burns (2010), Snyder (1966), Souza (2002), Thomas (1982).

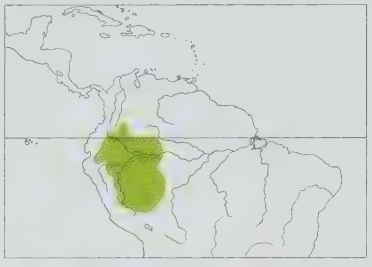
152. Opal-rumped Tanager

Tangara velia

French: Calliste varié **German**: Rotbauchtangare **Spanish**: Tangara Velia
Other common names: Silver(y)-breasted Tanager (*cyanomelas*)

Taxonomy. *Motacilla Velia* Linnaeus, 1758, Suriname.
Formerly placed with *T. callophrys* in a separate genus, *Tanagrella*. Molecular-genetic data indicate that the two are sister-species, and that *T. chilensis* is sister to both. Geographically isolated race *cyanomelas* differs somewhat from others in plumage, and may merit treatment as a separate species; review warranted. Four subspecies recognized.
Subspecies and Distribution.
T. v. iridina (Hartlaub, 1841) – E Colombia (from NW Meta and S Vichada) S to E Ecuador, E Peru and extreme N Bolivia (Beni), E to S Venezuela (Amazonas and Bolívar) and W Amazonian Brazil (E to R Negro, lower R Tapajós and NW Mato Grosso).
T. v. velia (Linnaeus, 1758) – the Guianas and N Brazil N of R Amazon (from R Negro E to Pará).
T. v. signata (Hellmayr, 1905) – NE Brazil (NE Pará).
T. v. cyanomelas (Wied, 1830) – coastal region of E Brazil from Pernambuco S to Rio de Janeiro.

Descriptive notes. 12–14 cm; 19–23 g. Dark tanager with marked geographical variation in plumage. Nominate race has crown and nape to back and scapulars deep velvety black, rump glistening opalescent yellowish to straw to greenish (varies with light), uppertail-coverts opalescent blue; tail black, feathers narrowly edged blue; lesser upperwing-coverts glistening pale greenish-blue, remaining wing-coverts and flight-feathers deep black, feathers of median coverts rounded and broadly tipped greenish-blue, greater coverts prominently edged greenish-blue, primary coverts, flight-feathers and tertials narrowly edged greenish-blue; forehead, side of head and side of neck medium blue, black band across throat and upper chest; mid-breast and sides shining violet-blue, lower breast, belly and undertail-coverts contrasting rich dark chestnut; iris dark brown; bill black; legs dark grey to blackish. Sexes similar, or female slightly duller than male. Juvenile dull and essentially featureless; immature recalls adult, but duller. Race *signata* is like nominate, but with small band of opal between blue forecrown and black of mid-crown; *iridina* has forecrown, side of head, side of neck and throat dark glistening violet-blue, much darker than nominate, rather ill-defined wreath of black spots mixed dark violet-blue across base of throat and upper chest, also wing edgings darker, dark cobalt-blue (not contrasting strongly); *cyanomelas* has silvery-green band across forehead (like *signata*) and face, throat and side of head deep blue, underparts silvery blue with irregular necklace of black spotting across chest, central lower underparts chestnut. Voice. Calls during foraging high, thin, rapid bursts of "sit" and "sit" and "tschip" notes, often c. 5–6 in a series. Weak song, in S Venezuela (Amazonas) a series of high, thin notes, quickly rising in pitch, then falling, "tiz-tiz-tiz-ti'ti'ti-é'é'ti-ti-ti-tz", c. 1–1·5 seconds in duration; song in E Peru described as a rising and falling broken series of high, wiry squeaks, "psi-psi-psi-psi-pis-psi"; song in E Ecuador a high-pitched, complex jumble of thin tinkling notes and then several high notes on same pitch, ending with slightly lower-pitched short jumble of notes, duration c. 3 seconds.
Habitat. Treetops in humid *terra firme* and *várzea* forest, less often forest borders, tall second growth, and trees in clearings. Lowlands to c. 500 m along E base of Andes; once to 1200 m in Venezuela; as high as 1075 m in Ecuador, and to 750 m (seldom higher) in Peru.
Food and Feeding. Fruits and arthropods; three stomachs contained only fruit. Pairs or small groups move in and out of canopy mixed-species flocks, often leaving to join faster-moving associations of *Cyanerpes* and other *Tangara* at fruiting trees, or to rest in emergent trees. May spend longer periods of time with mixed flocks containing insectivores during midday, then searching for arthropod prey by hopping along large canopy branches and peering, head down, first on one side and then on other in almost mechanical manner as it progresses outwards, or checking epiphytes or debris accumulated on limbs in canopy or subcanopy. Occasionally hitches around large canopy limbs and trunks, almost in manner of Black-and-white Warbler (*Mniotilta varia*). Rarely descends low to fruiting shrubs along forest borders (unlike many congeners). Single individuals, or sometimes two or three together, often perch on high open branches above canopy early in morning.
Breeding. Begging juvenile followed three adults on 18th Sept in Colombia (NE Guainía); eggs reported as being greyish-white, thickly dotted with darker shades of grey. No further information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common in Amazonia, where widespread; isolated E race *cyanomelas* uncommon and very localized. Occurs in numerous protected areas in Amazonia, where also extensive pristine habitat that is unprotected but at little immediate risk. In coastal E Brazil, *cyanomelas* reduced in numbers because of widespread deforestation; population confined largely to protected parks and reserves, e.g. Sooretama Biological Reserve, and may require listing as Near-threatened.
Bibliography. Athanas (2010a), Burns & Naoki (2004), David & Gosselin (2002a), Diamond & Lovejoy (1985), Gilliard (1941), Haverschmidt & Mees (1994), Hellmayr (1936), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Kleefisch (1991), McCarthy (2006), Mee *et al.* (2002), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Moore *et al.* (2009), Nehrkorn (1899), Pearson (1971), Penard & Penard (1910), Phelps & Phelps (1950), Pinto (1944a, 1944b), Remsen & Traylor (1983), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sick (1985, 1993), Snyder (1966), Souza (2002), Tostain *et al.* (1992), Willis (1977), Zimmer (1943a).



153. Opal-crowned Tanager

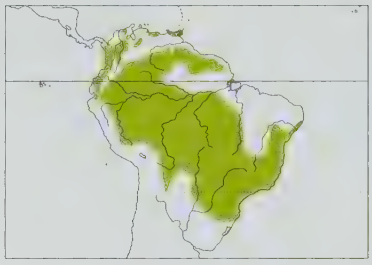
Tangara callophrys

French: Calliste à sourcils clairs **German**: Opalscheiteltangare **Spanish**: Tangara Opalina

Taxonomy. *H.*[*ypothlypis*] *callophrys* Cabanis, 1848, no locality = River Solimões, Brazil.

Formerly placed with *T. velia* in a separate genus, *Tanagrella*. Molecular-genetic data indicate that the two are sister-species, and that *T. chilensis* is sister to both. Monotypic.
Distribution. SE Colombia (E from lowlands of Caquetá and Putumayo) S through E Ecuador and E Peru (S to Puno), and W Brazil S of R Amazon (E to middle R Juruá and middle R Purús).

Descriptive notes. 14 cm; c. 21–24 g. Dark tanager with conspicuous opal brow. Has forecrown and broad supercilium glistening opal to opalescent yellow, hindcrown to back deep black, contrasting glistening opal to opalescent-yellow rump usually with tinge of bluish on some feathers; tail black, feathers obscurely edged dark blue; upperwing black, bend of wing and lesser and median coverts with feathers broadly tipped glistening dark blue, greater coverts broadly edged dark blue, flight-feathers and tertials narrowly edged dark blue; a band of black feathers around base of bill, side of head and underparts dark glistening blue with black feather bases (black showing through in a few places), centre of belly and undertail-coverts black; iris dark brown; bill black; legs black. Sexes similar. Immature undescribed. Voice. Call a high, thin "zit", often several times or accelerated into rapid twittering resembling that of *T. mexicana*. Song in E Ecuador a high-pitched, thin "sits-a-teak-a-te-te-te-te-te, seek, a", duration c. 1·5 seconds, slower and less complex than song of allied *T. velia*.
Habitat. Tall humid *várzea* and *terra firme* forest, and occasionally forest borders; infrequently in tall trees away from forest. Lowlands to c. 600 m at E base of Andes; locally (especially S Peru) to 1000 m.
Food and Feeding. Mixed diet of fruit and insects, probably not differing greatly from that of many others of genus. Three stomachs contained only fruit. Usually seen singly, in pairs or in trios, less often up to about seven together, associating with *Cyanerpes*, *Dacnis* and other *Tangara* in top of canopy and emergent trees early in morning, and may fly off to visit fruiting trees or vines. Later in morning and through midday often with canopy mixed-species flocks, foraging along large limbs, leaning down to inspect alternately one side and then the other in manner common to many congeners.
Breeding. No information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon; widely distributed across W Amazonia. Occurs in several large protected areas, including La Paya and probably Amacayacú National Parks (Colombia), Cuyabeno Wildlife Reserve, Limoncocha Biological Reserve and Sumaco Napo-Galeras and Yasuní National Parks (Ecuador), and Pacaya-Samiria National Reserve and Manu National Park (Peru); also in Serra do Divisor National Park (Brazil). Much of the habitat within this species' range is Amazonian lowlands is unprotected, but at little risk in near or intermediate term because of extremely low human population pressure.
Bibliography. de Bont (2003), Burns & Naoki (2004), Dunning (1982), Goodfellow (1901), Hellmayr (1936), Hilty & Brown (1986), Isler & Isler (1999), Moore *et al.* (2009), Munn (1985), O'Neill (1974), Pearson (1972), Phelps & Phelps (1950), Pinto (1944a), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sedano & Burns (2010), Sick (1985, 1993), Snethlage (1914), Souza (2002), Terborgh & Weske (1969), Zimmer (1943a).



Genus *TERSINA* Vieillot, 1819

154. Swallow Tanager

Tersina viridis

French: Tersine hirondelle **German**: Schwalbentangare **Spanish**: Tangara Golondrina

Taxonomy. *Hirundo viridis* Illiger, 1811, Sandwich Island; error = eastern Brazil.
This species has in the past been placed in its own family, Tersinidae, and in a subfamily Tersininae of present family. Molecular-genetic data indicate that it is embedded within present family, and forms a monophyletic group with *Dacnis* and *Cyanerpes*; all three genera have sexually dimorphic plumage, but present genus differs in broad flat bill, skeletal elements of palate and tongue, long wing, hole-nesting behaviour, and migratory habits. Three subspecies recognized.
Subspecies and Distribution.
T. v. grisescens Griscom, 1929 – Santa Marta Mts, in N Colombia.
T. v. occidentalis (P. L. Sclater, 1855) – E Panama (Darién), Colombia (except Santa Marta Mts), N Venezuela, Trinidad, the Guianas, W & E Ecuador, N & E Peru, N & W Brazil, NW & E Bolivia (except extreme SE) and NW Argentina.
T. v. viridis (Illiger, 1811) – E & S Brazil (from Pernambuco, Bahia, Goiás and S Mato Grosso S to Rio Grande do Sul), NE Bolivia, Paraguay and NE Argentina (Misiones).
Descriptive notes. 14 cm; 25·9–35 g. Short-tailed tanager with wide flat bill and short legs. Male nominate race has base of forehead, lores, ocular area (to just above eye) and throat black; rest of plumage mostly glistening bright turquoise-blue above and below, sometimes much bluer overall; primary coverts and flight-feathers black, narrowly edged turquoise-blue, tips of primaries black, tertials black, edged turquoise, tail feathers black with turquoise edges; centre of lower breast, belly and undertail-coverts white, turquoise flanks coarsely barred black, undersurface of tail greyish (turquoise edging visible); iris reddish-brown; bill black; legs dusky horn-grey. Female is mainly bright grass-green; base of forehead, face (to just above eye) and throat dingy grey, somewhat scaled and mottled with dusky brown, wing-coverts green, flight-feathers black, outer feathers narrowly edged green, inner ones and tertials more broadly edged and tinged green; centre of lower breast, belly and undertail-coverts pale yellow, sides and flanks yellow, coarsely barred green. Juvenile male is like female for first year, thereafter shows blue mottling in plumage but lacks black face mask; subadult male mainly blue above, with wing-coverts green, flight-feathers edged green, and

mostly green below, with yellowish lower underparts and dusky barring as on female; reports that male requires up to four years to acquire for full adult plumage need verification. Race *occidentalis* is essentially identical to nominate in plumage, but decidedly smaller (both wing and tail measurements); *grisescens* male is similar to previous, female differs in being mainly greyish-green (not bright grass-green). Voice. Often heard call a high, slightly blurred or buzzy and metallic "tza-link" or "tz'sink" (distinctive once learned), sometimes repeated at short intervals. Male's song is somewhat variable, in general a fairly rapid series of c. 10–15 shrill or squeaky notes and similar to that of *Thraupis episcopus*, e.g. in NE Peru "szuee, szuee, zoo-see-see-sue'le'ze-zoo-se-zu-weet", with rising and falling, sing-song pattern, and in Venezuela a more or less similar shrill series, "tzeet, whée-chee whée-chee whée-chee-zuwee".
Habitat. Dry, moist and humid forest borders, older second-growth woodland, shade trees over coffee, and partly cleared areas with scattered trees in clearings; also in or on top of canopy of humid forest and in tall riparian woodland. In NW parts of range occurs (or at least breeds) mainly in mountains, but farther S occurs widely across lowlands of S Amazonia S to N Argentina and SE Brazil. Sea-level to c. 1800 m in Venezuela, and mainly 50–1600 m (recorded to 2100 m) in Colombia; to 1400 m in Ecuador; and to 1500 m in Peru.
Food and Feeding. Fruits and arthropods; proportions of fruit and insect matter in diet believed to vary seasonally. Feeds heavily on fruit, especially fat-rich and protein-rich arils and larger ones, less often small berries but takes those of mistletoe (Loranthaceae), as well as some *Cecropia* catkins; frequently consumes *Michelia champaca* (Magnoliaceae) in S Brazil. Also reported eating moths (Lepidoptera) and larvae. Of 35 stomachs examined, 12 contained only vegetable matter and one only animal matter, and 22 contained both; contents mostly flying insects, e.g. flies (Diptera), ants (Formicidae), termites (Isoptera), and grasshoppers (Caelifera), also soft beetles (Coleoptera), seeds of Magnoliaceae and Araliaceae, and fruit pulp. Nestling diet insects for first few days, and again towards end of period (at 15–20 days, when feather growth occurs), otherwise up to 40% fruits. Notably sociable, occurring in small, loose single-species groups, even when breeding, and infrequently is loosely associated with mixed-species flocks or feeding associations around fruiting trees. Individuals or groups perch well up in trees, or in open on high exposed treetop perches, in distinctive upright posture, often for extended periods of time. Takes fruit while perched, or plucks fruit during short sallies followed by brief hovering; unlike *Tangara*, does not hang downward or upside-down to reach fruit. Most fruits, even large ones, swallowed whole, large seeds then discarded or regurgitated a short time later. Also sallies extensively for flying insects, especially swarming termites and ants, typically flying out 3–10 m in swift flight, often catching more than one insect, before returning to perch.
Breeding. Season mainly Feb–Jun in Colombia and Apr–May in Venezuela; in Brazil, Sept–Oct in Minas Gerais and various localities in SE, also birds in breeding condition in Jul, Aug and Oct in upper R Xingu and Mato Grosso. Solitary and loosely colonial, several pairs may nest in close proximity in favourable sites; male may defend small territory or guard nesting hole, but classic territoriality almost non-existent. Pair formation includes extended bowing, sometimes accompanied by bouncy hopping and chasing, with female believed to initiate pairing, male then accompanying her; breeding males also bow extensively to each other. Nest built by female, a weak shallow cup of various fibrous materials, apparently always lined with fine black palm fibres, placed in hole in old stone building, hole in cliff, riverbank or stone wall, cavity under bridge, or hole in tree or in dirt bank; uses existing hole, but can dig own hole in soft earth. Clutch typically 3 eggs, occasionally 4, white; incubation by female, period 13–17 days, nestling period c. 24 days; male largely ignores mate during incubation, but becomes attentive at hatching and sometimes helps with feeding of young. Male will breed while in subadult plumage.
Movements. Resident and short-distance migrant, possibly also nomadic. Local and seasonal in many regions, especially in N of range. Over much of its Amazonian range, may be either resident or nomadic when not breeding. N populations in Venezuela, Colombia and Ecuador undertake elevational migrations, some also moving considerable distances geographically, but timing and precise distances of movements unknown; how much of this movement represents wandering, as opposed to true migration, is not known. In Venezuela, present in N cordilleras Feb–Jul (breeding) and absent remainder of year, and present S of Orinoco mainly Jul–Feb but numbers erratic and somewhat inconstant; migratory (or possibly nomadic) flocks of 20–125 individuals seen in NE Venezuela in late Aug. In E lowlands of Ecuador, numbers highest in Oct–May and species scarce or absent during remainder of year. Those in extreme S of range, in N Argentina and S Brazil, also migratory, moving N during austral winter. Groups of 100 or more reported in Brazil, e.g. in Minas Gerais appearing in Mar–May/early Jun in Viçosa and in Jun–Aug in metropolitan centre of Belo Horizonte.
Status and Conservation. Not globally threatened. Widespread but local; in some areas seasonally common, although numbers highly variable. Possibly only a non-breeding visitor in E Panama. Occurs, at least seasonally, in numerous protected areas, among them Henri Pittier and Yacambú National Parks (Venezuela), and El Paujíl Reserve and Farallones de Cali, Sierra Nevada de Santa Marta (or close to it) and Chiribiquete National Parks (Colombia); also across much of Amazonia in both protected and unprotected areas, and in SE Brazil in Itatiaia and Iguaçu National Parks, among others. Only a few areas within its extensive range are threatened with deforestation, and the species appears to prosper in partially disturbed areas if fruit resources reliable and suitable holes or cavities for nesting available.

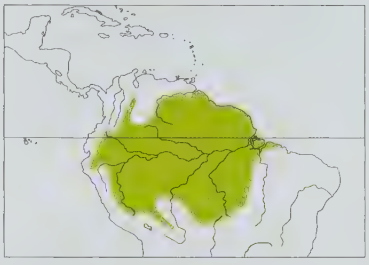
Genus *DACNIS* Cuvier, 1816

155. White-bellied Dacnis

Dacnis albiventris

French: Dacnis à ventre blanc **German**: Weißbauchpitpit **Spanish**: Dacnis Ventriblanco

Taxonomy. *Pipraeidea albiventris* P. L. Sclater, 1852, "Bogotá".
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Present species was formerly placed in a monotypic genus, *Hemidacnis*. Monotypic.
Distribution. Very locally from C & S Colombia (Meta, Guainía and Putumayo) and S Venezuela (Amazonas) S to E Ecuador (Napo and Pastaza) and NE Peru (Loreto and Ucayali); also SW Pará, in C Brazil.



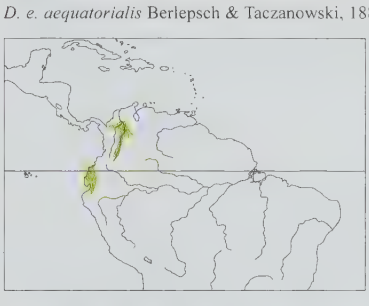
Descriptive notes. 11 cm; two birds 11 g and 11·5 g. Conical and pointed bill among the shortest of genus. Male has conspicuous broad black mask from base of forehead, lores and back through eye to rear ear-coverts, where it abruptly turns downwards slightly to sharp point (imparts distinctive appearance); otherwise mainly rich cobalt-blue above, scapulars and back with variable amount of black, tail black, outer feathers narrowly edged blue; lesser upperwing-coverts mostly cobalt-blue, median and greater coverts black, broadly edged and tipped dark cobalt-blue, primary coverts and flight-feathers black, edged blue, outer web of tertials blue, inner web mostly dusky; throat to mid-breast rich cobalt-blue like upperparts, rest of underparts white (sharply and squarely demarcated from blue of upper breast), flanks somewhat clouded and mottled bluish; iris golden-yellow; bill blackish; legs grey. Female is plain and rather confusing; brownish olive-green to yellowish olive-green above, including side of head to below eye, lores darker, with foreface and side of head slightly scaly; lower back, rump and uppertail-coverts strongly tinged olivaceous, flight-feathers and tail dusky brown; throat to belly dull yellowish, side of throat, side of breast, and flanks and undertail-coverts clouded greyish-brown; iris light brown to greyish-brown. Immature male is like female, but flight-feathers contrastingly blackish; older immature male also has greyish-yellow eyes and whitish belly, thus beginning to look like adult. Voice. In S Venezuela, gives a soft, silky "seeeee" in flight; in Peru, recorded calls include a high, descending "tseew", a rising "tee" and a thin "tu", often delivered in series. Song, noted in Peru, is a high, lisping "seee-suleee", mixed with a trilled "tip-tu'tee't't't't" and various call notes; it can alternatively be described as a rather slow series of short, high-pitched notes and phrases, "tzet tza'leet saleet..." and similar, these separated by intervals of 1–3 seconds.
Habitat. Canopy of tall humid *terra firme* forest and forest borders in Venezuela; has been reported in canopy of gallery forest in Brazil, and in forest and in trees and shrubs at lake edges and in clearings in E Peru. Its range, as well as scattered known localities, suggests an association with nutrient-poor soils and heavily weathered soils in *terra firme* forest. Lowlands to 400 m; to 200 m in Venezuela.
Food and Feeding. Not well known. Small berries taken; observed to return repeatedly to a medium-height *Miconia* tree at edge of forest in Venezuela. In Venezuela, pairs and small groups of 3–10 containing males, females and immatures follow rapidly moving mixed flocks of *Tangara* species and other forest-treetop birds. Gleans insects from high outer foliage, especially from pinnately compound foliage of large legume trees. Often hangs upside-down or uses acrobatics to glean and inspect foliage, then flies off in straggling groups or pairs to distant fruiting trees and shrubs, where associates briefly with manakins (Pipridae), small tyrant-flycatchers (Tyrannidae) and other tanagers as they forage for small berries.
Breeding. No information.
Movements. No information.
Status and Conservation. Not globally threatened. Rare and poorly known; possibly occurs mainly in regions of sandy-soil forests. Widely distributed, but presence recorded at only a small number of sites within its range. May occur in some protected areas, but is found also within vast area of intact but unprotected forest that is unlikely to be at risk.
Bibliography. Hellmayr (1936), Hilty (1999, 2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Moore *et al.* (2009), O'Neill & Pearson (1974), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sick (1960), Zimmer (1942a).

156. Black-faced Dacnis

Dacnis lineata

French: Dacnis à coiffe bleue **German**: Maskenpitpit **Spanish**: Dacnis Carinegro

Taxonomy. *Motacilla lineata* J. F. Gmelin, 1789, French Guiana.
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Present species often treated as conspecific with *D. egregia*, but the two differ in plumage and are geographically isolated from each other; further investigation required. Monotypic.
Distribution. E base of Venezuelan Andes (extreme SE tip of Táchira), E Colombia (Norte de Santander S along base of Andes to W Meta, then generally from C Meta and Guainía) S to E Ecuador, E Peru and N Bolivia (S to Beni and Cochabamba), E to S & SE Venezuela S of R Orinoco (S & C Amazonas; Bolívar except NE), the Guianas and most of Amazonian Brazil (E to NE Pará and EC Mato Grosso).



Descriptive notes. 11 cm; 9·5–13 g. Bill thin and sharply pointed. Male has crown turquoise-blue, broad, sharply defined black mask extending from forehead and lores through eye and straight back to hindneck, where continuous with black of nape and back (looking like "bandit's mask" tied around head); scapulars, rump, uppertail-coverts, and most of underparts bright turquoise; lesser upperwing-coverts turquoise, median and greater coverts black, flight-feathers and tertials black, tertials edged turquoise, tail black; centre of lower breast, belly, undertail-coverts and underwing-coverts white; iris yellow; bill black; legs blackish. Female is uniformly brownish-olive above, underparts similar but paler, becoming buffy white on belly; underwing-coverts white; iris yellow, like that of male. Juvenile undescribed. Voice. Call, in Ecuador, a thin, high "tzlip"; in Peru, call described as modulated, high "trree", distinctive once learned. Song, in Pará (Brazil), a rather feeble series of blurry trills, e.g. "bze'e-bu'u'u't, pzip, bz'e'e...tr'e'e'e, tzzz-teee...", and so on, delivered in rambling, irregular sequence.
Habitat. Canopy of tall, humid *terra firme* and *várzea* forest, at forest borders, scattered trees in forest clearings, and occasionally along gallery or riverine forest. Lowlands to c. 1100 m, smaller numbers to 1400 m.
Food and Feeding. Fruits and insects. Observed to eat small berries of melastomes, and to take bits of *Cecropia* catkin. Of 19 stomachs examined, 17 contained only vegetable matter and two contained both vegetable and animal matter, including fruit, seeds, berries, and insects. Usually occurs singly, in pairs or, less often, in small groups; rarely (or possibly seasonally), groups of up to 20 or so individuals reported in Brazil. Regularly follows mixed-species flocks for variable periods of time, then often flies off to rest with other tanagers and flock-members in high vine tangle; joins fruit-eating species at fruiting trees. Forages actively in canopy, only occasionally dropping lower, and rarely down to c. 10 m above ground. Forages for insects in outer foliage and in vine tangles, and may hang downwards or employ other acrobatics to obtain insects from undersurfaces of leaves. Seen to take pieces of *Cecropia* catkin by making short aerial sallies.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Fairly common to common. Occurs in many protected areas across vast Amazonian range, among them Nukak Natural Reserve and Cahuinarí, La Paya, Chiribiquete and Amacayacu National Parks (Colombia), Cuyabeno Wildlife Reserve and Yasuní National Park (Ecuador), Manu, Pacaya-Samiria and Tambopata National Reserves and Tingo Maria, Cordillera Azul and Manu National Parks (Peru), Madidi National Park (Bolivia), and Serra do Divisor and Pacaas Novos National Parks (Brazil). This species' range also includes vast areas of unprotected habitat that is considered to be at little risk.
Bibliography. Beebe (1916), Brosset (1964), Burns (1997a), Dick *et al.* (1984), Fry (1970), Haverschmidt & Mees (1994), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Mee *et al.* (2002), Meyer de Schauensee & Phelps (1978), Moore *et al.* (2009), Munn (1985), Naumburg (1930), Novaes (1969), Pacheco *et al.* (2007), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sick (1985, 1993), Snyder (1966), Souza (2002), Storer (1969), Terborgh & Weske (1975), Tostain *et al.* (1992), Willis (1977), Zimmer (1942a).

157. Yellow-tufted Dacnis

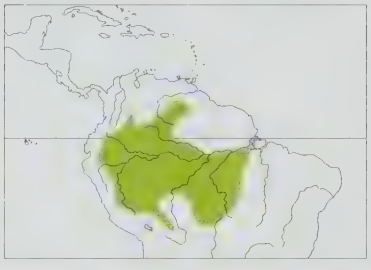
Dacnis egregia

French: Dacnis à plumets jaunes **German**: Gelbsteißpitpit **Spanish**: Dacnis Egregio

Taxonomy. *Dacnis egregia* P. L. Sclater, 1855, "Bogotá".
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Present species often treated as conspecific with *D. lineata*, but the two differ in plumage and are geographically isolated from each other; further investigation required. Two subspecies recognized.
Subspecies and Distribution.
D. e. egregia P. L. Sclater, 1855 – N Colombia in S Córdoba (upper R Sinú), Antioquia (lower R Cauca and Nechí Valley), and middle and upper Magdalena Valley from Santander S to Tolima and Huila.
D. e. aequatorialis Berlepsch & Taczanowski, 1884 – W Ecuador (Esmeraldas S to El Oro).

Descriptive notes. 11 cm. Bill sharply pointed. Male nominate race has crown turquoise-blue, conspicuous broad black mask extending from forehead and lores through eye and rearwards, where continuous with black of rear crown nape and back; lesser upperwing-coverts, rump and uppertail-coverts, as well as throat and most of underparts, turquoise with slightly greenish tinge; tail black; pectoral tuft and bend of wing bright yellow; mid-breast, middle of belly, undertail-coverts and underwing-coverts bright yellow; iris bright yellow to orange-yellow; bill black; legs blackish. Differs from similar *D. lineata* in having yellow pectoral tuft and bend of wing, centre of lower breast and belly bright yellow (not white), underwing-coverts yellow (not white), also blue areas slightly greenish-tinged, less blue. Female is uniformly greyish-olive above, sometimes with faint bluish tinge; throat and breast greyish-olive, rather well demarcated from rich deep yellow of centre of lower breast, belly and undertail-coverts; pectoral tuft (visible at bend of wing) bright yellow, underwing-coverts yellow; very like female of *D. lineata*, but more greyish and less brownish above, yellower below. Race *aequatorialis* has plumage more turquoise-green, less blue, than nominate, female differs in having slightly contrasting greyish head (uniform in nominate). Voice. Call, in W Ecuador, a thin, high-pitched "tsrrip". Song not described.

On following pages: 158. Yellow-bellied Dacnis (*Dacnis flaviventer*); 159. Turquoise Dacnis (*Dacnis hartlaubi*); 160. Black-legged Dacnis (*Dacnis nigripes*); 161. Scarlet-thighed Dacnis (*Dacnis venusta*); 162. Blue Dacnis (*Dacnis cayana*); 163. Viridian Dacnis (*Dacnis viguieri*); 164. Scarlet-breasted Dacnis (*Dacnis berlepschi*).



Habitat. Broken forest and hill forest, plantations, second growth, and scattered trees in gardens and overgrown clearings; to lesser extent in canopy of dry and humid forest. Lowlands to c. 900 m.
Food and Feeding. Fruits, presumably also some arthropods; seen especially at fruiting *Miconia* and trees with small berries. Occurs singly, in pairs, and occasionally in family groups, regularly with mixed-species flocks in forest canopy. Sometimes lower at fruiting trees and shrubs at forest edges and in clearings and gardens. Restless and active, foraging in canopy, occasionally lower; may hang downwards to reach insects on undersides of leaves. Foraging behaviour much like that of *D. lineata*.
Breeding. No information.
Movements. Apparently resident.
Status and Conservation. Not assessed. Probably not globally threatened. Both populations generally uncommon and somewhat local. Occurs in a few protected areas, including El Paujil Reserve (Magdalena Valley, in W Boyacá), in Colombia, and seen with some regularity near Tinalandia Eco-Lodge, in Ecuador; other protected sites where it possibly occurs include Cayapas-Mataje and Cotocachi-Cayapas Ecological Reserves, in NW Ecuador. Within this species' range deforestation is extensive, although it appears able to survive in broken habitat with patches of forest and second growth.
Bibliography. Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Storer (1969).

158. Yellow-bellied Dacnis

Dacnis flaviventer

French: Dacnis à ventre jaune **German**: Gelbbauchpitpit **Spanish**: Dacnis Ventriamarillo

Taxonomy. *D.[acnis] flaviventer* d'Orbigny and Lafresnaye, 1837, Yuracares, Bolivia.
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Monotypic.
Distribution. Lowlands of SE Colombia (from W Caquetá and Vaupés) S to E Ecuador, E Peru and Bolivia (W Santa Cruz), E to S Venezuela (Amazonas and W half of Bolívar) and W Brazil (E to approximately R Negro, SC & WC Pará and N half of Mato Grosso).

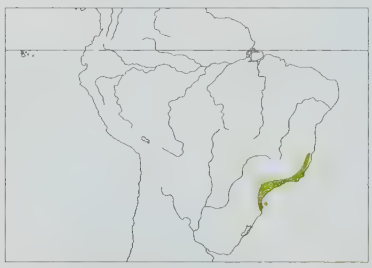
Descriptive notes. 11 cm; 12–14 g. Bill thin and sharply pointed, and iris bright red in both sexes. Male is distinctive, has narrow black mask extending from base of forehead and lores rearwards to meet black of nape and back, crown rather dark moss-green, small throat patch black; scapulars, side of back, rump and uppertail-coverts bright yellow; tail and upperwing-coverts, flight-feathers and tertials deep black; malar area to side of neck and underparts, including undertail-coverts, rich yellow; iris bright red; bill black; legs grey. Female is plain and undistinguished, except for red eyes; pale brownish-olive above, wing and tail darker, dusky brown; dingy yellowish-buff below, obscurely mottled olive on breast and sides and slightly more yellowish on lower underparts and undertail-coverts. Juvenile evidently undescribed. Voice. Calls high and thin, e.g. "zeet", and slightly more buzzy "zrret", also as "tzueEET", given frequently during foraging. A series of well-separated single "p'tzeeEEep" notes (about 3–4 seconds apart) may represent a type of song.
Habitat. Humid *várzea* and low-lying forest, forest borders and taller second growth, especially along river borders, on river islands, and in canopy and emergent crowns of trees in humid *terra firme* forest. Lowlands to c. 350 m in Venezuela; to 500 m (probably higher) in Colombia, to c. 700 m (smaller numbers to at least 1150 m) in Ecuador, and to c. 1000 m in Peru.
Food and Feeding. Fruit and arthropods; also nectar. Of nine stomachs examined, two contained only vegetable matter, six only animal matter and one both; contents included fruit, homopterans, and caterpillars. In all lowland areas regularly observed to take nectar from upper-level and canopy-height flowering *Combretum* vines. Usually observed singly or in pairs, seldom in groups, although groups of up to 15 individuals reported; regularly with mixed-species flocks, often only for brief periods of time. Readily comes to fruiting trees with others frugivores to eat fruit and berries, and may visit small fruiting trees in shrubby clearings and gardens. In Peru, observed when foraging for insects on new leaves 15 m up. Generally forages and perches high, infrequently below c. 10 m except at fruiting shrubs in clearings.
Breeding. One nest described, in Dec in NE Ecuador. A frail shallow open cup, rather thin and sparse, slightly oblong, external diameter c. 61 × 70 mm, internal diameter 45 × 53 mm, external surface wrapped with vine-like fern (*Microgramma*) and spider webs (much as nest of *D. venusta*), lined with soft, thin rootlets, dry grasses and moss, well concealed within clump of mistletoe (Loranthaceae) 6·5 m up on upper branch in 7-m Lauraceae tree, supported by five branches (one from tree, four from mistletoe), and c. 5 m from a river; contained two nestlings. No further information available.
Movements. Mainly resident. Possibly some seasonal elevational movements associated with birds that occur in higher part of range.
Status and Conservation. Not globally threatened. Uncommon to fairly common, and widespread across W & C Amazonia. Found in many protected areas, including Yapacana National Park (Venezuela), La Paya and Amacayacu National Parks (Colombia), Cuyabeno Wildlife Reserve and Yasuni National Park (Ecuador), Pacaya-Samiria National Reserve and Manu National Park (Peru), Madidi National Park (Bolivia), and Serra do Divisor, Jaú and Amazonica National Parks (Brazil). In addition, there are within its range vast amounts of intact but unprotected forest that is considered to be at little risk.
Bibliography. Dunning (1982), Hellmayr (1910), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Moore *et al.* (2009), Munn (1985), Remsen *et al.* (1987), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sheldon & Greeney (2008), Sick (1985, 1993), Snethlage (1913), Souza (2002), Spencer (2009), Storer (1969), Taczanowski (1884), Zimmer (1942a).

159. Turquoise Dacnis

Dacnis hartlaubi

French: Dacnis de Hartlaub **German**: Türkispitpit **Spanish**: Dacnis Turquesa
Other common names: Turquoise Dacnis-Tanager, Pseudodacnis

Taxonomy. *Dacnis hartlaubi* P. L. Sclater, 1855, La Cumbre, Valle del Cauca, Colombia.
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Present species has been placed in a separate genus, *Pseudodacnis*, in part because its bill is heavier than others of genus; plumage and eye colour similar to those of *D. lineata*, although foraging behaviour closer to that of some *Tangara*; further study, including molecular-genetic analysis, required. Monotypic.
Distribution. W & C Colombia: both slopes of W Andes in Valle, and W slope in Risaralda; C Andes in Antioquia and Quindío; W slope of E Andes in Santander (above San Vicente), Boyacá and Cundinamarca (R Bogotá); and head of Magdalena Valley in Huila.



Descriptive notes. 11 cm. Bill heavier than that of other members of genus, and nearly as heavy as bill of *Tangara*. Male has turquoise crown enclosed by narrow black mask extending from base of forehead and lores straight back through eye and expanding to join black of nape and back; scapulars, side of back, rump and uppertail-coverts turquoise-blue, wing and tail black, tertials edged and tipped blue; small and rather narrow black throat patch; broad malar area to side of neck and underparts, including undertail-coverts, turquoise-blue; iris bright yellow; bill blackish; legs dark grey. Female is plain, mainly dull brown above, wing-coverts and flight-feathers edged buff (no wingbars), pale greyish-buff below, more yellowish-white on centre of belly; iris orange-yellow, paler and duller than male's. Juvenile undescribed. Voice. High-pitched, undistinctive calls include flat "tsit" and "sic", mostly singly; also a high-pitched, thin and buzzy "tzzleeet". Possible song, by male, consists of 3 high thin introductory notes followed by thin trill.
Habitat. Humid forest, forest borders, second-growth borders, and scattered trees in highland clearings and shade trees over coffee, especially *Inga* and *Cordia alliodora*. Mainly in humid regions with fairly high rainfall, but most records (especially recent sightings) in partly to heavily disturbed regions with scattered trees. Generally c. 1350–2200 m; recorded at 300–1700 m on Pacific slope of W Andes (Valle del Cauca) and c. 1500 m in C Andes (Quindío).
Food and Feeding. Fruits; also some arthropods. One stomach contained fruit. Most often seen singly, foraging fairly high and in outer foliage; also singles follow mixed-species flocks in forest canopy, especially along borders. Works actively in foliage and on small outer twigs, where it gleans insects and reaches up, out and downwards in manner of *Hemithraupis*; both sexes observed also to work sluggishly along mossy branches, inspecting bromeliads with foraging movements that suggest *Tangara*.
Breeding. One male in breeding condition in Aug in Cundinamarca (E Andes). No other information.
Movements. Probably resident; believed not to make seasonal movements, but further information needed.
Status and Conservation. VULNERABLE. Restricted-range species: present in Colombian East Andes EBA, Colombian inter-Andean Slopes EBA and Chocó EBA. Rare, very local and declining. Has almost certainly disappeared from many areas where it formerly occurred. Prior to c. 1980 had been recorded in Valle del Cauca, Huila, Quindío, Antioquia, Risaralda, Cundinamarca and Boyacá; since c. 1980 has been reported in Santander (Reinita Cielo Azul Reserve), Boyacá (Serranía de las Quinchas), WC Cundinamarca (R Bogotá area), Antioquia (two areas near Támesis) and one site in Risaralda (W Andes). At present, largest surviving population may be in Serranía de las Quinchas (in Santander–Boyacá). Loss of suitable humid forest to agricultural activities and human settlement has been the most significant threat; colonization and subsequent deforestation probably reached a peak in late 1970s to early 1980s, however, and some areas are now abandoned and in various stages of regrowth. The ability of this species (apparently) to utilize secondary habitats may enable it, to some extent, to avoid becoming more seriously threatened. It occurs in Reinita Cielo Azul Reserve, in Santander, and close to Farallones de Cali National Park, in Valle del Cauca; Serranía de las Quinchas at present remains largely unprotected.
Bibliography. Álvarez-Rebolledo *et al.* (2007), Anon. (2010a), Botero & Verhelst (2001), Butchart & Stattersfield (2004), Cortes (2009b), Hellmayr (1936), Hilty (1985, 2009a), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Munves (1975), Quevedo *et al.* (2006), Remsen *et al.* (2010), Salaman *et al.* (2008), Stattersfield & Capper (2000), Stiles *et al.* (1999), Storer (1969).

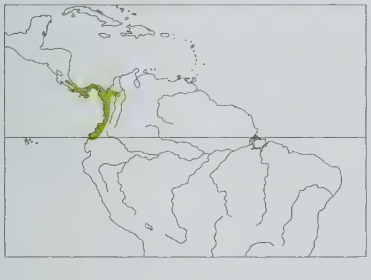
160. Black-legged Dacnis

Dacnis nigripes

French: Dacnis à pattes noires **German**: Schwarzfußpitpit **Spanish**: Dacnis Patinegro

Taxonomy. *Dacnis nigripes* Pelzeln, 1856, Rio de Janeiro, Brazil.
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Monotypic.
Distribution. Coastal region of SE Brazil from C Espírito Santo S to Rio de Janeiro, São Paulo, E Paraná and NE Santa Catarina, including Santa Catarina I.

Descriptive notes. 11 cm; 11–15·5 g. Small, short-tailed dacnis. Male has lores and small area around eye black (forming small mask), narrow central throat patch black; rest of head and nape greenish-blue to pale turquoise-blue; mantle black (forming obvious triangle-shape), scapulars and back to uppertail-coverts pale turquoise or greenish-blue; tail black, with some outer feathers obscurely edged blue; upperwing-coverts black with turquoise-blue fringes, flight-feathers black, innermost ones with turquoise edges; underparts from chest to undertail-coverts pale turquoise; iris dark reddish-brown; bill black; legs dusky to blackish. Distinguished from very similar *D. cayana* mainly by blackish (not pinkish) legs, slightly smaller black throat patch, black of upperparts more restricted and confined to mantle, primaries and secondaries all black with essentially no blue edgings, usually no pale colour at bill base, shorter wing and tail, also blue areas more greenish-tinged, less blue (this often difficult to deter-



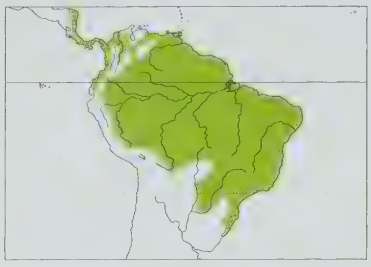
mine). Female is dull brownish with olive tinge above, crown, side of head, rump, uppertail-coverts and often part of scapulars strongly tinged turquoise-blue, uniform pale sandy-buff below, legs dusky. Subadult male plumage, retained for first year, is much like female, but with irregular patches of greenish-blue or turquoise on underparts. Voice. No information.
Habitat. Humid forest borders, second growth, and forest clearings. Lowlands to c. 850 m, in decreasing or seasonal numbers to 1700 m.
Food and Feeding. Feeds on insects, small fruits, also nectar of flowers and a few seeds. Six stomachs contained animal and vegetable matter, including *Miconia* berries, dry seeds of *Xylopia* (Annonaceae), and other unidentified fruits, beetles (Coleoptera), flies (Diptera), hymenopterans, and small caterpillars. Observed to eat berries of *Trema micrantha*, *Miconia*, arillate seeds of *Xylopia*, *Clusia* and *Schinus*, as well as bananas from feeding station at Ubatuba, in São Paulo. Nectar from flowers of *Erythrina* believed to be an important food resource; other nectar resources documented as being exploited include *Mabea brasiliensis* (Euphorbiaceae), the introduced bottlebrush tree (*Callistemon rigidus*), and *Spirotheca passifloroides* (Malvaceae) flowers at Canavieiras, in Paraná. Seen to visit flowers (for nectar or insects) of introduced eucalypt (*Eucalyptus*); at Intervales State Park, observed while feeding in yellow flowers of large *Schizolobium parahyba* (Fabaceae) trees; fed at flowers of unidentified tree in Itatiaia National Park in late Oct. Nestling diet at one nest was fruit of *Pouteria ramiflora* (Sapotaceae) and *Rapanea ferruginea* (Myrsinaceae), probably also small arthropods. Recorded in single-species groups of 2–5 individuals early in morning, and has been reported with *D. cayana* and other species in mixed flocks; has been noted also as feeding at nectar resources with *D. cayana*. May concentrate locally in small groups during certain periods of year (mainly in austral winter). Searches for small insects by gleaning from leaf and branch surfaces well up in trees (mainly above 25 m); may occasionally sally short distances for flushed insects.
Breeding. Nests found Dec to mid-Feb, and nest-building recorded Oct–Dec. Nests sometimes in relatively close proximity (in one case as close as 15 m), with no aggression between pairs, and has been suggested that the species may nest in loose "groups" close to favourable food resources. Nest built by both sexes, a cup made from almost entirely of lichen, especially *Usnea*, or *Tillandsia* sometimes the principal material, usually well camouflaged 3–20 m (mostly c. 5–12 m) above ground and suspended beneath branch or woven into hanging *Usnea* or *Tillandsia*, in usually lightly foliaged tree with high density of epiphytes (including lichens, bromeliads, orchids and moss) on branches and trunks, e.g. one nest a partially concealed basket-like cup c. 5–8 cm in diameter and suspended from epiphytes 20 m up and half-way out on limb in large *Schizolobium parahyba* tree in cacao plantation, another 5·5 m up in large (18 m tall) fig tree (*Ficus*) in pasture 200 m from second-growth forest; all reported nests were in medium to fairly large isolated tree or in tree in patch of second growth near large tract of forest. Few other data: at one nest clutch 2 eggs, incubation by female, period 14 days, chicks fed by male alone for first five days, thereafter by both sexes, nestling period 13–14 days.
Movements. Apparently wanders widely, and is an irregular seasonal and altitudinal migrant in some areas. Records around Rio de Janeiro and other coastal areas are mostly from winter months (i.e. Jul), when observed in small groups. Erratic seasonal concentrations occur at fruiting and flowering trees, but these not constant from year to year. Seasonal movements, and possible patterns, require further documentation.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Rare to uncommon within small global range. Often confused with very similar *D. cayana*, making accurate estimates of population difficult. Only five certain records from Paraná (some possibly involving escaped cagebirds). Specimen supposedly from Lago Santa, in C Minas Gerais, regarded as involving a labelling error, but the species may occur in extreme S Minas Gerais. Recent records (possibly even breeding in mountains) around Caetés, in Espírito Santo, suggest that its range may be larger than was previously known. Occurs in many tracts of protected Atlantic Forest in SE Brazil, including Desengaño, Intervales, Alto do Ribeira, Ilha do Cardoso and Serra do Tabuleiro State Parks, Itatiaia, Serra dos Órgãos and Tijuca National Parks, Tinigua Biological Reserve, Ubatuba Experimental Station, Cananéia–Iguape–Peruíbe Environmental Protection Area, and Artex and Spitzkopf Ecological Reserves. Greatest threats are deforestation and trapping for cagebird trade (which is illegal); because of its rarity, it is greatly prized in captivity. Encouraging recent evidence indicates that the species does not require separate elevational ranges for breeding and wintering.
Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Gonzaga (1983), Ihering (1900), Isler & Isler (1999), Parker & Goerck (1997), Parrini & Raposo (2008), Piacentini *et al.* (2006), Ridgely & Tudor (1989, 2009), Sick (1985, 1993), Souza (2002), Stattersfield & Capper (2000), Storer (1969), Whittaker *et al.* (2010), Zimmermann (1995).

161. Scarlet-thighed Dacnis

Dacnis venusta

French: Dacnis à cuisses rouges **German**: Rotschenkelpitpit **Spanish**: Dacnis Muslirrojo

Taxonomy. *Dacnis venusta* Lawrence, 1862, Panama Railroad, Panama.
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Two subspecies recognized.
Subspecies and Distribution.
D. v. venusta Lawrence, 1862 – both slopes of mountains in Costa Rica (from Guanacaste and Alajuela) S to C Panama (Canal Zone).
D. v. fuliginata Bangs, 1908 – E Panama (Caribbean slope in Darién) E across N base of W & C Andes of Colombia to lower Cauca Valley and middle Magdalena Valley in Antioquia, and S on Pacific coast and slope to NW Ecuador (Pichincha).



Descriptive notes. 12 cm; 15–17 g. Small dacnis with red eyes and sharp-pointed bill; male unusual in having very dark underparts. Male nominate race has forecrown, lores, ocular area, small post-ocular point, narrow gular stripe and entire breast, belly and undertail-coverts deep greenish-black; rest of crown, nape and sides of head and neck turquoise (looking like a blue "half-hood"), centre of mantle, back, rump and uppertail-coverts also bright turquoise-blue, longest uppertail-coverts black, side of back black, scapulars turquoise-blue; tail and upperwing and its coverts are deep black; thighs red (distinctive, but frequently concealed); iris deep red; bill black; legs dark grey. Female has side of head and upperparts dull dark bluish-green, brighter and more bluish on side of neck and malar area, dullest on side of back, and becoming bluish to turquoise on rump; wings and tail dusky; throat mostly greyish, changing to dull greyish-brown on chest, and to greyish-olive on breast, sides and flanks, breast faintly tinged blue, belly and undertail-coverts yellowish-buff; iris dark red, sometimes reddish-brown. Immature male is much like female, but duller and greyer on head; subadult male similar, but tinged blue on most of upperparts, chest sooty or mixed sooty and buff; more advanced immature male shows well-defined turquoise "half-hood", scapulars, back and rump, but small mask dusky (not black), and central throat and underparts dull greyish-white, undertail-coverts tinged buff, iris red; in Costa Rica young male shows some evidence of adult plumage by Sept (following early-year fledging), but remains duller than adult during first full breeding season. Voice. Calls include thin "woit" or "wheit" with upward inflection, and scratchy "bzik". Song, in Costa Rica, 2–3 scratchy trills ending in high squeaky notes, "bzeek, bzeek, bzeek"; song weak and infrequent, or easily overlooked.
Habitat. Mainly humid to wet forest, forest borders and young to old second growth, including canopy of mossy cloudforest vegetation. Post-breeders may wander well away from forest into scattered trees and woodlots where fruiting trees and shrubs present. In Costa Rica mainly 500–1200 m on Caribbean slope and c. 900–1500 m on Pacific slope, but often moving into lowlands after breeding. In Colombia mostly in or near foothills at 150–600 m, but regularly moving out on to coastal plain and in small numbers upwards to 1100 m.
Food and Feeding. Fruits and arthropods. In Costa Rica observed to eat wide variety of berries and arillate seeds, including those of *Clusia*, *Zanthoxylum*, *Sapium* and *Dendropanax*, and in Panama seen to inspect flower stems of *Pourouma*; in Colombia regularly took small berries from several species of *Miconia* and other melastomes, and often ate pieces from *Cecropia* catkins. Contents of two stomachs were vegetable matter, including fruit pulp and figs; five others contained no more than 30% insect matter. Occurs in pairs when breeding; at other times most often seen in small groups, frequently with mixed flocks that contain honeycreepers and other tanagers. Most recorded foraging activity above 6–9 m.
Breeding. Breeding reported Mar–May in Costa Rica. Nest a frail, shallow open cup composed of coarse and tough rootlets, tendrils and fern rachises, covered with pieces of green fern, placed 12–15 m up (two nests in Costa Rica) and saddled between two twigs amid foliage. One nest contained two nestlings. No other information.
Movements. Significant post-breeding dispersal to lower elevations in Costa Rica and Panama; on Pipeline Road in Panama, numbers fluctuate dramatically, in some months common, in others scarce or nearly absent. During 16-month study at 1000 m On Pacific slope in Colombia, recorded only in Dec, with main population centre at much lower elevation. Changing seasonal abundance of small berries has been suggested as a likely reason for the erratic movements of this species.
Status and Conservation. Not globally threatened. Uncommon to locally or seasonally common over much of range. Now greatly reduced through forest loss in montane regions of lower Central America. Two old, undated and now lost specimens were apparently from Guayas, in SW Ecuador, farther S than current S limit of range. Occurs in several protected areas, including Braulio Carrillo, Tapantí and Chirripó/La Amistad National Parks (Costa Rica), La Amistad, Soberanía, Chagres and Darién National Parks (Panama), Los Katíos and Farallones de Cali National Parks (Colombia) and the Río Palenque Scientific Centre (W Ecuador). Although the species' range includes some intact habitat that is not protected but at relatively low risk, forest loss in lowlands and foothills is extensive and ongoing; in areas such as W Ecuador, where loss of lowland forest outside protected areas is approaching 100%, this species is vulnerable.
Bibliography. Burns & Racicot (2009), Buskirk (1976), Carriker (1910), Davis (1972), Dunning (1982), Garrigues & Dean (2007), Greenberg (1981c), Greenberg & Gradwohl (1980), Hartman & Brownell (1961), Hilty (1997, 2009a), Hilty & Brown (1986), Isler & Isler (1999), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Skutch (1962b), Slud (1964), Stiles & Skutch (1989), Storer (1969), Strauch (1977), Wetmore *et al.* (1984), Wheelwright *et al.* (1984).

162. Blue Dacnis

Dacnis cayana

French: Dacnis bleu **German**: Blaukopfpitpit **Spanish**: Dacnis Azul

Taxonomy. *Motacilla cayana* Linnaeus, 1766, Cayenne, French Guiana.
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Eight subspecies recognized.
Subspecies and Distribution.
D. c. ultramarina Lawrence, 1864 – Caribbean slope from extreme E Honduras S to Panama and NW Colombia (on W side of Gulf of Urabá).
D. c. callaina Bangs, 1905 – W Costa Rica and SW Panama (Chiriquí).
D. c. napaea Bangs, 1898 – N Colombia from Santa Marta region S to E side of Gulf of Urabá and across lower Magdalena Valley.
D. c. coerebicolor P. L. Sclater, 1851 – N Colombia (lower Cauca Valley and middle and upper Magdalena Valley).
D. c. baudoana Meyer de Schauensee, 1946 – Pacific coast of W Colombia (from Baudó Mts) S to W Ecuador (to at least Pichincha, perhaps formerly S to Guayas).
D. c. cayana (Linnaeus, 1766) – E Colombia (E from Meta and Arauca), Venezuela (in Maracaibo region, and generally E of Andes and S of R Orinoco), Trinidad, the Guianas, and Brazil (except S & E).
D. c. glaucogularis Berlepsch & Stolzmann, 1896 – S Colombia (Caquetá and Putumayo), E Ecuador, E Peru and N & E Bolivia.
D. c. paraguayensis C. Chubb, 1910 – E & S Brazil (Maranhão and Ceará S to C Mato Grosso and Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).
Descriptive notes. 11–12 cm; c. 15 g (*paraguayensis*), 10–15·5 g (other races). Small dacnis with thin and pointed bill. Male nominate race has lores and small area around eye black (forming small mask), narrow central throat patch black; rest of head and nape bright turquoise-blue; mantle and back black, narrowing to a point just above rump, with scapulars, side of back, rump and uppertail-coverts bright turquoise-blue; tail black, a few outer feather pairs obscurely edged blue; upperwing and its coverts black, median coverts narrowly tipped blue, greater coverts, primary coverts, flight-feathers and tertials prominently edged blue; entire underparts from chest to undertail-coverts turquoise; iris dark red to reddish-brown; bill dusky, basal half or more of lower mandible pale grey, gape pinkish; legs and feet pinkish. Female is mainly green, paler below, with dull bluish head and typically with greyish throat. Immature male is like female, but black areas of mask, throat and back much duller; more advanced immature has patches of black in plumage. Races differ mainly in tone of blue (lighter or darker) of male plumage, and in colour of head and back of female:

callaina differs from nominate in brighter cerulean plumage of male; *ultramarina* male differs from nominate in having medium-blue (not lighter turquoise) plumage; *napaea* male has plumage rich cobalt-blue, intermediate between previous (which slightly lighter) and next race (which even darker), female has bluish-violet head; *coerebicolor* male is darkest and most deeply coloured of all races, bluish-violet to purplish, female has bluish-violet head like previous; *baudoana* male has notably dark violaceous-blue plumage, blue colour more purple-tinged than previous, female with more extensive and brighter blue on head than female of next race; *glaucogularis* male differs from nominate in having blue colours lighter turquoise-blue and throat not so deep black, female has deep blue crown and side of head; *paraguayensis* is most similar to last, but paler blue. VOICE. Calls are high, thin "tsit" notes and a high "chit" or "chit-it" or "tseep"; weak, easily overlooked, and apparently not given often. Song, in NE Peru, an equally weak, high-pitched series of several thin lisping and buzzy notes, delivered slowly, "twéezze, twéezze, twéezze, ...", that seems to end inconclusively; sometimes a single note.

Habitat. Moist to wet *várzea* and *terra firme* forest, second growth, and semi-open areas with scattered trees and shrubs; also riverine or gallery forest. Lowlands to c. 750 m, locally or seasonally higher; recorded to 1200 m in Costa Rica, to 1000 m in Panama, and to 1400 m in South America, regularly to 2000 m in Urubamba Valley (Peru), and to 1650 m in Bolivia.

Food and Feeding. Fruits and arthropods. Of 28 stomachs examined, 17 contained only vegetable matter and seven only animal matter, and four contained both; contents included fruit, seeds, hymenopteran pupae, dung beetles (Scarabaeoidea), orthopterans, and spiders (Araneae). Of 267 recorded observations in Trinidad, 49% involved birds searching for insects, 44% of birds taking fruit, and 7% of birds at flowers (where may have taken insects or nectar); in Panama, percentages were 64% insects and 36% plant material. In Trinidad, 26 species of fruit taken, of which 39% were *Miconia* berries, 24% species in family Euphorbiaceae, and 10% species in Ulmaceae. In Costa Rica, arillate seeds of *Clusia* were an important food item. Elsewhere, has been reported at wide variety of plants, mostly those with small seeds, and flowers. Usually seen singly or in pairs or threes, seldom in small groups, although groups of up to twelve individuals reported; most often with mixed-species flocks, and regularly follows other birds to fruiting trees. Generally forages high, especially when searching for insects. In Trinidad 69% of all insect-hunting was done on leaves, 13% on branches and twigs and 12% on flowers and seedheads, and 6% were sallies to air. Insects usually taken from leaves, 70% of time from tops of leaves, often by leaning, reaching or hanging upside-down in acrobatic manner. Reported also as examining stems and slender branches, probing flowers and bromeliads, and lunging and sallying for insects. Foraging, at least locally, is evidently non-random, the birds flying directly to brownish areas of leaf damage.

Breeding. Breeding activity reported in May–Oct, with fledglings in Nov, in Costa Rica. Three adults observed to feed nestlings at one nest. Nest a deep, almost pouch-like cup of soft fibres and seed down, suspended between leafy twigs in outer part of tree, two nests in Costa Rica were 5·5 m and 8 m up in isolated trees. Clutch 2 eggs, white with dark markings. No further information available.

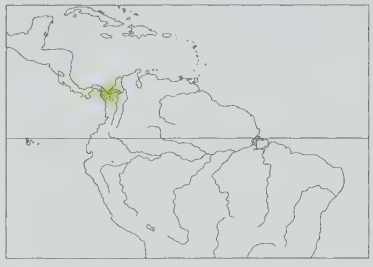
Movements. Predominantly resident. Some minor seasonal elevational movements; on Pacific slope (R Anchicayá) of Colombia, reported as high as 1050 m only in Dec, Jan, Apr and Jul.

Status and Conservation. Not globally threatened. Fairly common to common and widely distributed throughout its large range. Occurs in many protected areas, and vast areas of its range in the Guianas and Amazonia contain extensive intact habitat that is unprotected but at little immediate risk. The species is affected most by deforestation in Central America (races *callaina* and *ultramarina*) and in SE Brazil (*paraguayensis*). E & S Brazilian population of race *paraguayensis* occurs in numerous protected areas, among them Sooretama and Augusto Ruschi (Nova Lombardia) Biological Reserves, and Itatiaia, Tijuca and Iguaçu National Parks.

Bibliography. Allen (1891), Bangs & Noble (1918), Beebe (1909), Belton (1985), Burns (1997a), Burns *et al.* (2002, 2003), Davis (1972), Dick *et al.* (1984), ffrench (1991), Fry (1970), Garrigues & Dean (2007), Gonzaga (1983), Greenberg (1981b), Greenberg & Gradwohl (1980), Haverschmidt (1948, 1968), Haverschmidt & Mees (1994), Hilty (1997, 2003), Hilty & Brown (1986), Ihering (1900), Isler & Isler (1999), Layard (1873), McCarthy (2006), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Mitchell (1957), Moojen *et al.* (1941), Moore *et al.* (2009), Narosky & Di Giacomo (1993), Naumburg (1930), Novaes (1973), Parker & Goerck (1997), Pearson (1971), de la Peña & Rumboll (1998), Pinto (1944a), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Sazima *et al.* (1993), Schäfer & Phelps (1954), Schubart *et al.* (1965), Schulenberg *et al.* (2007), Sick (1985, 1993), Skutch (1962b), Slud (1964), Snow & Snow (1971), Snyder (1966), Souza (2002), Stiles & Skutch (1989), Storer (1969), Strauch (1977), Terborgh & Weske (1969), Tostain *et al.* (1992), Walker (2001), Zimmer (1942a).

163. Viridian Dacnis

Dacnis viguieri



French: Dacnis vert **German**: Panamapitpit **Spanish**: Dacnis Verdoso

Taxonomy. *Dacnis viguieri* Oustalet, 1883, Isthmus of Panama, on shores of the Gulf of Darién.
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Monotypic.

Distribution. E Panama (E Darién) and NW Colombia (N Chocó, NW Antioquia and SW Córdoba).

Descriptive notes. 10 cm. Small dacnis with sharp, pointed bill. Male has lores, mantle and tail black; rest of head, nape, side of back, rump, uppertail-coverts and throat and entire underparts mainly shining opalescent turquoise-green, rump brighter and bluer and underparts slightly paler; upperwing-coverts dull pale green, primary coverts and outer flight-feathers contrastingly black, secondaries increasingly edged green on outer webs, tertials broadly edged green; iris yellow; bill black above, paler below; legs greyish. Female is mainly dull olive above, with lores and tail dusky, outer primaries dusky, pale yellowish-green below, more yellowish on belly; bare parts as for male. Juvenile apparently undescribed. VOICE. No information.

Habitat. Humid forest and along forest borders, also in scrubby second growth; reports of individuals in dry forest and scrub may represent wandering or seasonal movements, but more information needed. Lowlands to 700 m; may wander to higher levels.

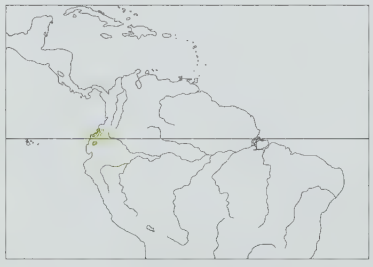
Food and Feeding. Little information. Has been seen in canopy of flowering *Erythrina* trees in E Panama.

Breeding. No information.

Movements. No information.

Status and Conservation. Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Darién lowlands EBA. Rare. Considerable number of specimens from both slopes of N end of Serranía de Baudó, in N Chocó (Colombia), suggests that this species was once numerous, at least locally in this region, but this area is rarely visited by naturalists and ornithologists, and current status of the species there is unknown. Much of the forest in R Sinú and Gulf of Urabá region has been converted to banana plantations and grassland for cattle ranches, and it is likely that the species occurred here, too, although there are apparently few old records and few or no recent records. Considerable amount of forest remains, however, in E Panama and in Baudó region of N Chocó, although these areas will be at risk if the Pan-American highway is eventually completed. Reasons for the species' apparent decline, even in forested areas, remain uncertain; seeming absence may be due, in part, to lack of research and fieldwork in appropriate habitats (e.g. foothill regions, rather than lowlands). Since about 1990, at least, fieldwork in suitable sites has been impeded, to some extent, by political instability and various illegal activities. Recent mapping of this species' range suggests that it might be more widespread than was believed, but the the mapping has been contested as overoptimistic; further study required.

Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Davis (1972), Haffer (1975), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Renjifo *et al.* (2002), Ridgely & Gwynne (1989), Salaman *et al.* (2008), Stattersfield & Capper (2000), Wetmore *et al.* (1984).



164. Scarlet-breasted Dacnis

Dacnis berlepschi

French: Dacnis à poitrine rouge **German**: Rotbrustpitpit **Spanish**: Dacnis Pechirrojo

Taxonomy. *Dacnis berlepschi* E. J. O. Hartert, 1900, Lita, north-western Ecuador.
This genus and *Cyanerpes* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Monotypic.

Distribution. SW Colombia (Pacific slope of Nariño) and NW Ecuador (S to Pichincha, but mainly in Esmeraldas).

Descriptive notes. 12 cm. Distinctive colourful dacnis with thin and pointed bill. Male has inconspicuous narrow black mask from base of forehead through lores and eye, somewhat variable; rest of head, throat and chest bright violaceous blue; mantle, back and scapulars deep violaceous blue with line-like silvery-blue streaks, rump paler unstreaked silvery blue; tail black; lesser and median upperwing-coverts violaceous blue, rather inconspicuously streaked silvery blue, greater coverts dusky, broadly edged pale blue; flight-feathers and tail black, narrowly edged pale blue, edging very inconspicuous on primaries and tail, more visible on tertials; broad band across breast scarlet, bleeding into yellow on lower breast and buff to white on centre of belly and undertail-coverts; iris yellow; bill black; legs dark grey. Female is mainly plain brown above, including wing-coverts and flight-feathers; paler, more buffy brown, below, becoming buffy white on centre of belly and undertail-coverts, with rather diffuse red wash forming broad band across centre of breast; bare parts as for male. Juvenile resembles female, but has brown (not yellow) eyes. VOICE. Song, in Ecuador, described as a very fast, evenly high-pitched series of thin notes, "tsit-tsitsitsitsitsitsitsitsitri".

Habitat. Canopy of humid and wet foothill forest, treefalls, and forest and river borders; less often older second growth and settled areas with scattered trees in clearings adjacent to forest. At c. 200–800 m; smaller numbers to 1200 m, possibly seasonally.

Food and Feeding. Poorly known. Feeds on fruit, insects and probably nectar, but diet not well documented. In Ecuador, singles, pairs and small groups seen, about equally with mixed-species flocks and independently of them. Sometimes forages or moves around high in canopy; at other times ranges much lower, especially at forest borders and in clearings and regrowth vegetation.

Breeding. Family groups with juveniles and immatures observed most often in Jun–Nov dry season. No other information.

Movements. Apparently resident.

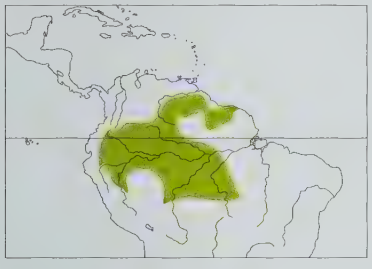
Status and Conservation. VULNERABLE. Restricted-range species: present in Chocó EBA. Rare to uncommon; poorly known. Has extremely limited distribution in Colombia (vicinity of Ricaurte and Barbacoas) which is rapidly being lost to combination of oil palm (*Elaeis guineensis*) plantations, human colonization, logging, cattle-ranching, mining, hunting and other activities. Since c. 2000, forest loss estimated at 3·8% per year and an accumulated loss of c. 38% of all forest cover for this area. The bulk of the species' range lies in Ecuador, where its forest habitat has already almost entirely disappeared or, where it survives, is extremely fragmented. Protected areas include Río Nambí Community Nature Reserve (Colombia) and Biological Corridor Awacachi, Río Palenque Scientific Centre, Cotacachi-Cayapas Ecological Reserve, Gran Reserva Chachi, Canandé Reserve and Silanche Reserve (Ecuador), as well as the Mache-Chindul and Cayapas-Mataje Ecological Reserves (also Ecuador). Colombian protected areas have been beset by a variety of illegal activities, and most of the area where this species occurs in Colombia has been destabilized for more than a decade by political unrest and guerrilla activity, which has made enforcement of regulations in protected areas difficult.

Bibliography. Anon. (2010a), Butchart & Stattersfield (2004), Carriker (1959), Hartert (1901), Hilty & Brown (1986), Isler & Isler (1999), Jahn *et al.* (2002), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Rothschild (1901), Salaman *et al.* (2008), Stattersfield & Capper (2000), Storer (1969).

PLATE 18 ➤

PLATE 18

inches 2
cm 5



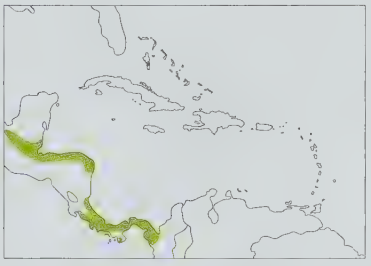
Genus *CYANERPES* Oberholser, 1899

165. Short-billed Honeycreeper

Cyanerpes nitidus

French: Guit-guit à bec court **Spanish**: Mielerito Piquicorto
German: Kurzschnabel-Naschvogel

Taxonomy. *Coereba nitida* Hartlaub, 1847, northern Peru.
This genus and *Dacnis* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Monotypic.
Distribution. SE Colombia (from E base of Andes in Caquetá, Vaupés, and Guainía) E to S Venezuela (Amazonas and NW & C Bolívar), Guyana, Suriname and possibly French Guiana, S through E Ecuador to NE Peru (S to Pasco, Huánuco and Ucayali) and W Brazil (E to E Amazonas and, S of R Amazon, to N Rondônia and extreme NW Mato Grosso).



Descriptive notes. 9 cm; 8–10·2 g. Small honeycreeper with short and slender bill only slightly decurved near tip, with lower mandible almost straight; bill shortest in genus, only c. 10 mm long (c. 14 mm for *C. cyaneus*). Male has lores, area around eye and short pointed postocular mark black, narrow black throat patch widening onto chest; rest of head and entire upperparts and underparts rich purplish-blue; short tail black; upperwing-coverts and flight-feathers black, underwing-coverts blackish; iris dark brown; bill black; legs reddish-pink. Female has loral area dusky, reaching back to short postocular streak, turquoise-green line above this, pale blue triangular patch from base of lower mandible nack to start of ear-coverts, narrow arc of blue below eye; crown to rump and uppertail-coverts bright green, tail dusky black, edged green; upperwing-coverts green, flight-feathers and tertials black, edged green; throat and centre of underparts buffy yellow, breast and sides green, streaked white, underwing-coverts yellowish-white; legs dull pink. Immature male is much like female, but duller. Voice. Call, in Peru, a short, high-pitched, rising "tsee"; in NE Brazil, "tsik tsik". No song has been identified.
Habitat. Humid *terra firme* forest and forest borders. In Venezuela occurs also in slightly less humid, lower-stature forest on nutrient-poor, reddish-soil, yellowish-soil and white-sand forests. Lowlands, to c. 500 m in Venezuela; to c. 400 m in Colombia and Ecuador, and to 1000 m in Peru.
Food and Feeding. Diet poorly known. Three stomachs contained only vegetable matter, including fruit and seeds. Shorter bill of this species may represent an adaptation for a more frugivorous and less insectivorous diet than in congeners. Regularly found with canopy-level and emergent-level mixed-species flocks containing other honeycreepers and other tanagers, and, unlike most congeners, is almost always seen singly or in pairs, rather than in groups. Singles or pairs also regularly forage in canopy with variably sized groups of *C. cyaneus* and *C. caeruleus*, irrespective of whether these two are with other species. Foraging behaviour poorly known. In Brazil observed to forage in canopy, mostly at heights of 15–30 m, where it was often in fruiting trees, and seen to search for insects on branches and in foliage.
Breeding. No information.
Movements. Resident. No evidence that this species wanders widely at some seasons, as does *C. cyaneus*.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common, and widespread at rather low density. Should occur in a number of protected areas in Venezuela, SE Colombia, and adjacent E Ecuador, Peru and NW Brazil. The species' range includes a vast amount of intact but unprotected lowland forest that is unlikely to be at risk in the foreseeable future.

Burns *et al.* (2003), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Novaes (1978), Ottema (2002), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Sick (1985, 1993), Souza (2002), Spencer (2009), Storer (1969), Willis (1977), Zimmer (1942b).

166. Shining Honeycreeper

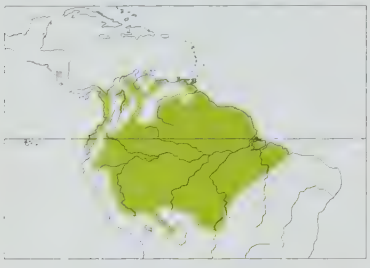
Cyanerpes lucidus

French: Guit-guit brillant **German**: Azurnaschvogel **Spanish**: Mielerito Reluciente

Taxonomy. *Coereba lucida* P. L. Sclater and Salvin, 1859, Guatemala.
This genus and *Dacnis* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Present species thought to form a superspecies with *C. caeruleus*; in the past sometimes treated as conspecific, but the two are sympatric in extreme E Panama and adjacent NW Colombia. Two subspecies recognized.
Subspecies and Distribution.
C. l. lucidus (P. L. Sclater & Salvin, 1859) – foothills of Gulf–Caribbean slope of S Mexico (E Chiapas) through NC Guatemala, Belize (Cockscomb Mts) and N Honduras to NE Nicaragua.
C. l. isthmicus Bangs, 1907 – Costa Rica (entire E slope, and Pacific slope in San José) S to E Panama and adjacent extreme NW Colombia.
Descriptive notes. 10 cm; c. 11 g. Small honeycreeper with slender and somewhat decurved bill c. 14–15 mm long (intermediate in length between bills of *C. nitidus* and *C. caeruleus*). Male nominate race is mainly bright purplish-blue, including scapulars, slightly paler blue on forehead; lores, orbital area, throat patch (extending to upper breast), median and greater wing-coverts, flight-feathers, tertials and short tail black; underwing-coverts dark; iris dark brown; bill blackish; legs bright yellow, claws black. Female has head dull greenish-blue, dark blue malar stripe, and buff smudges and streaks on forehead and side of head; upperparts, including long uppertail-coverts, pale green, tail dusky, tinged and edged green; lesser and median upperwing-coverts pale green,

greater coverts dusky, broadly edged pale green, flight-feathers dusky, narrowly edged pale green; throat buff, underparts buffy white, diffusely streaked dark blue and buff, sides and flanks pale green; legs and feet greenish-yellow. Immature male is like female, but head more greenish (less blue) and streaking on breast mainly greyish and buff; immature male moults into adult plumage Nov–Jan (when slightly less than one year of age) in Costa Rica. Race *isthmicus* male is similar to nominate, but smaller, with shorter and more slender bill, also blue colour of head slightly paler than that of body (more or less concolorous in nominate), female duller green on back and with greener, less blue-tinged, head. Voice. Generally rather quiet. Most vocalizations high and not especially distinctive, e.g. high, sharp chittering notes, a high, thin "seee seee seee seeuu", and other high, trilled or insect-like notes; also reported is a dry "tsip" and slightly rattling "tsrrrp". Male delivers a high, thin "pit pit pit pit-pit, pit-peet pit pit-peet pit pit..." from top of tree for long periods of time; this possible song often little more than repetition of a single note.
Habitat. Inhabits canopy of humid forest, and adjacent forest borders and tree-shaded clearings, pastures and second growth; in all areas is most numerous in humid regions. Occurs from sea-level up to 1500 m (mainly foothills) in Mexico, to 1200 m in Costa Rica; c. 300–1000 m, rarely to 1600 m, in Panama and c. 100 m in Colombia. This species favours humid and wet regions, where seasonal swings in resource availability less pronounced than those in drier habitats favoured by *C. cyaneus*.
Food and Feeding. Fruits, seeds and arthropods. Of 15 observations of foraging in Panama, 44% were of fruit-eating, 37% were of insect-hunting, and 19% were at flowers. Eats a variety of fruits, but arils of several trees, shrubs and vines, especially *Clusia*, apparently favoured. Nestling diet believed to be mostly insects at first, thereafter fruit material. Forages alone, in pairs and in little family groups, only occasionally gathering in larger groups; associates with mixed-species flocks, especially those consisting of other honeycreepers and other tanagers, or forages independently of them. Often seen at fruiting and flowering trees with such species as *Dacnis cayana* and *C. cyaneus*; feeding then occurs with little evidence of aggression, but sometimes aggressive towards *C. cyaneus*, and may displace it from food sources. Limited data suggest that foraging is much like that of congeners. Uses long slender bill to extract arils; swallows small seeds, and perches beside flowers and probes, presumably for nectar. Gleans insects and spiders (Araneae) from thin bare vines, and may hop nervously and actively along large canopy branches, leaning downwards to peer at sides. Often hovers, sallies to air, or flutters for insects; may hover to pluck arils from fruit, and probes small curled dead leaves.
Breeding. In Costa Rica peak season thought to be Apr–Sept, but may breed regularly as late as Oct, and fledglings observed in May, Jul and late Oct. Nest built by female alone, a shallow, very thin cup (eggs may be visible from below) composed of slender fibrous strands, resembling nest of a manakin (Pipridae), rim attached with spider webs to slender twig fork, and usually well hidden within foliage (especially terminal foliage) 6–9 m up in tree in clearing by forest. Clutch 2 eggs (colour apparently undescribed); incubation by female, constancy of two females 70% and 81%, respectively, incubation period 12–13 days; chicks fed by both adults, female feeding more than male, nestling period 13–14 days.
Movements. Resident. Limited seasonal movements, presumably in response to changing fruit or nectar resources, reported by some authors, but not by others.
Status and Conservation. Not globally threatened. Uncommon to fairly common in Mexico; farther S, mostly a common resident in foothills and to lesser extent in lowlands in wetter portions of range. In Panama local on Pacific slope, with apparently few records from Veraguas and none from Chiriquí, but more numerous E of Canal Zone, extending E in small numbers to E Darién; in Canal Zone much more numerous on Caribbean slope, local or erratic (possibly seasonal) on Pacific slope. In general, less numerous than *C. caeruleus*. Occurs, or should occur, in numerous protected areas, including Palenque National Park (Mexico), Tikal National Park (Guatemala), Cockscomb Basin Forest Reserve (Belize), Capiro–Calentura National Park (Honduras), Indio-Maíz Biological Reserve (Nicaragua), Braulio Carrillo National Park (Costa Rica) and Soberanía, Chagres, Metropolitan and Darién National Parks (Panama). This species' range also includes considerable intact habitat that is unprotected. Loss of lowland and foothill forest has reduced its range dramatically in some areas.
Bibliography. Beehler (1980), Cherrie (1892a), Davis (1972), Edwards (1972), Garrigues & Dean (2007), Greenberg (1981c), Hartman & Brownell (1961), Hilty & Brown (1986), Howell & Webb (1995), Isler & Isler (1999), Moynihan (1962c), Ridgely & Gwynne (1989), Russell (1964), Salaman *et al.* (2008), Skutch (1972), Slud (1964), Smithe (1966), Stiles & Skutch (1989), Storer (1969), Wetmore *et al.* (1984).

167. Purple Honeycreeper



Cyanerpes caeruleus

French: Guit-guit céruléen **German**: Purpurnaschvogel **Spanish**: Mielerito Cerúleo
Other common names: Yellow-legged Honeycreeper

Taxonomy. *Certhia caerulea* Linnaeus, 1758, Suriname.
This genus and *Dacnis* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Present species thought to form a superspecies with *C. lucidus*; in the past sometimes treated as conspecific, but the two are sympatric in extreme E Panama and adjacent NW Colombia. Five subspecies recognized.
Subspecies and Distribution.
C. c. chocoanus Hellmayr, 1920 – extreme E Panama (Darién) and Pacific coast of Colombia (from Chocó) S to W Ecuador (S to El Oro).
C. c. caeruleus (Linnaeus, 1758) – Colombia (on E slope of E Andes in Boyacá), Venezuela (mountains of Falcón, coastal range from Carabobo E to Sucre, N Monagas, Delta Amacuro, also W Amazonas and Bolívar), Suriname, French Guiana (probably also lowlands of Guyana), and NC Brazil (S to R Tapajós and NW Maranhão).

On following pages: 168. Red-legged Honeycreeper (*Cyanerpes cyaneus*); 169. Green Honeycreeper (*Chlorophanes spiza*); 170. Golden-collared Honeycreeper (*Chlorophanes pulcherrimus*).

C. c. longirostris (Cabanis, 1851) – Trinidad.
C. c. hellmayri Gyldenstolpe, 1945 – Potaro Highlands, in Guyana.
C. c. microrhynchus (Berlepsch, 1884) – Venezuela (W & S Zulia, W base of Andes in Táchira and Mérida, E base S from SE Lara, and N & W Amazonas S of R Orinoco), and Colombia (N base of W Andes in R Sinú drainage and E to middle Magdalena Valley, also E of Andes from Meta and Caquetá) S to E Ecuador, E Peru, N Bolivia (S to Santa Cruz), and Amazonian Brazil (E to mouth of R Amazon and WC Mato Grosso).

Descriptive notes. 10 cm; 7·8–14 g. Small honeycreeper with long (14–23 mm), slender and usually distinctly decurved bill. Male nominate race is mainly bright purplish-blue, including scapulars; forecrown and side of head slightly paler, lores, area around eye and extending to short point behind eye, and narrow throat patch black; short tail black; upperwing-coverts and flight-feathers black, underwing-coverts dusky; iris dark brown; bill black; legs bright yellow, claws black. Female is plain green above, including wing-coverts; flight-feathers dusky, outermost feathers edged greenish-yellow, inner ones more heavily edged green, tertials mainly dull green with narrow dusky border on inner edges; forecrown somewhat mixed dull greyish and green, occasionally with a few inconspicuous streaks of blue, lores and ocular ring buff, side of head cinnamon-buff with whitish and dusky streaks, long narrow bright blue malar stripe; throat dark buff, underparts light whitish-buff to yellowish-buff with rather diffuse bluish-green streaks, centre of belly and undertail-coverts light yellow, underwing-coverts dull yellowish-white; legs dull greenish-grey. Juvenile resembles female, but paler and plainer below and generally lacks blue malar and blue streaking on underparts; immature male generally like female; subadult male retains greenish female-like plumage, but has black lores and throat, and black wings and tail, and may show dark purplish-blue mottling on body plumage. Races differ mainly in size and bill length: *chocoanus* is slightly smaller than nominate, bill shorter and forecrown slightly paler blue, female yellower below and with much less streaking; *longirostris* is very similar to nominate, but bill longer and body plumage tends to be more purple; *hellmayri* differs from nominate in larger size, significantly longer and heavier bill, male more violaceous blue in colour, female with darker, more cinnamon-buff, throat and more greenish (less bluish) tinge on side of body; *microrhynchus* is extremely similar to nominate, but msaller, with bill decidedly shorter. Voice. High-pitched vocalizations much like others of genus; gives high, buzzy or lisping "zree" or "zhree" and "psit" notes, often constantly. No song described.

Habitat. Canopy of tall humid *terra firme* and *várzea* forest, wooded borders, second growth, open woodland and tree-scattered clearings, river edges, plantations and gardens; mainly in humid lowland and foothill areas, perhaps only locally or seasonally in riparian woodland and other humid habitats within dry zones. In most areas common from lowlands up to c. 800 m; irregularly or locally to 1400 m in Colombia (once to 2300 m), regularly to 1200 m in Ecuador, to 1400 m in Peru; as high as 1800 m in tepuis of S Venezuela; in Potaro Highlands of Guyana (race *hellmayri*), found at c. 800 m.

Food and Feeding. Fruits and arthropods. Of six stomachs examined, four contained only vegetable matter and one only animal matter, and one contained both; contents were orchid seeds, fruit and insects. Spiders (Araneae) found in an additional stomach. Of 237 records of foraging in Trinidad, 40% were of insect-hunting, 31% of fruit-eating, and 29% at flowers where both insect-eating and nectar-feeding occurred; proportions of insects, fruit and nectar varied seasonally; only twelve species of fruit were taken, and of total fruit items 35% were *Trema micrantha*, 18% the arils of *Clusia* and 18% small fruits of Euphorbiaceae. Occurs in pairs, family units, and small to large single-species groups, either alone or in association with mixed-species flocks, but especially with other canopy-dwelling honeycreepers and tanagers. Not uncommonly, a dozen or more may forage with large mixed flocks in humid forest canopy, and often rest, along with other small frugivores and insectivores, on high open branches in tops of emergent forest trees at dawn. Like congeners, is restless, highly active and nervous, often wing-flicking and fidgeting as it hops along large canopy limbs, peering at bark surfaces, leaning down to check sides or undersides, hovering to pluck arils or small fruits, sallying or fluttering for flying insects, and quickly moving through foliage. Occasionally descends low, both within tall forest and along forest borders and in tree-shaded clearings, rarely even to ground. In Trinidad, average foraging height was 8 m; 63% of insect-seeking was done on branches and twigs, 17% in foliage, 15% in sallies to air, and 5% on flowers and seedheads; individuals often hung downwards to take insects from beneath twigs. Observations elsewhere generally agree with those in Trinidad.

Breeding. Breeding reported in Apr and Jun in Trinidad and Oct and Dec in Brazil (Pará); begging juvenile in Nov in C Peru (Pasco). Nest in Trinidad a small cup placed less than 2 m above ground in hollow of stump; two nests in Brazil were, respectively, 2 m and 3 m up, one at end of a branch. Clutch 2 eggs, white, blotched with dark reddish-brown and chocolate-brown, and with some ash-grey stains; nestlings fed by both adults. No other information.

Movements. Some local or seasonal movements, apparently in response to varying fruit and nectar resources, but pattern and seasonality of these poorly documented. On Pacific slope (R Anchicayá) of Colombia, recorded as high as 1050 m only in Apr.

Status and Conservation. Not globally threatened. Fairly common to common over most of range; locally distributed W & N of Andes. Occurs in many protected areas and, E of Andes, its range includes vast areas of intact habitat that is unprotected but at little risk. Areas of greatest habitat loss within this species' range are in N & W Colombia and W Ecuador.

Bibliography. 168. Red-legged Honeycreeper

Cyanerpes cyaneus

French: Guit-guit saï **German**: Türkisnaschvogel **Spanish**: Mielerito Patirrojo
Other common names: Blue Honeycreeper

Taxonomy. *Certhia cyanea* Linnaeus, 1766, Suriname.

This genus and *Dacnis* were previously regarded as members of a separate family, Coerebidae, but later placed in present family on basis of similarities in skull anatomy; molecular phylogenies indicate that the two genera are sisters and form a monophyletic group with *Tersina*. Possible species status of race *holti* may merit investigation because of its geographical isolation. Geographical variation slight, and some races may not warrant recognition; proposed race *ramdseni* (described from Cuba, where probably introduced), subsumed into nominate. Eleven subspecies tentatively recognized.

Subspecies and Distribution.
C. c. carneipes (P. L. Sclater, 1860) – SE Mexico (from San Luis Potosí on Gulf slope and Oaxaca on Pacific slope) S, including Cozumel I (off NE Quintana Roo) to Panama, including Coiba I and Pearl Is, and NW Colombia (upper Sinú Valley, at N end of W Andes, in Córdoba).
C. c. gemmeus Wetmore, 1941 – Serranía de Macuira (Guajira Peninsula), in N Colombia.
C. c. eximius (Cabanis, 1851) – N Colombia (Santa Marta region, Sierra de Perijá, and W slope of E Andes in Santander) and W & N Venezuela (W Zulia, base of both slopes of Andes, mountains of N Falcón and Yaracuy, and coastal cordillera from Carabobo E to Sucre); also Margarita I.
C. c. cyaneus (Linnaeus, 1766) – E Venezuela (Monagas, Delta Amacuro and Bolívar E of R Caura); Trinidad; the Guianas and NW Brazil (S to R Negro and mouth of R Amazon).
C. c. tobagensis Hellmayr & Seilern, 1914 – Tobago I.
C. c. pacificus Chapman, 1915 – W Colombia (Pacific coast S from Baudó Mts) and W Ecuador (S to Pichincha).
C. c. gigas Thayer and Bangs, 1905 – Gorgona I, off W Colombia.
C. c. brevipes (Cabanis, 1851) – middle and lower R Amazon from at least Manacapurú E to middle R Tocantins.
C. c. dispar J. T. Zimmer, 1942 – Colombia E of Andes (from Meta and R Negro–R Guainía region) E to SW Venezuela (Amazonas), NW Brazil (E to R Negro and R Juruá), E Ecuador (rare), and NE Peru (S to Yarinacocha).
C. c. violaceus J. T. Zimmer, 1942 – SE Peru, N Bolivia, and W Brazil (E to Mato Grosso).
C. c. holti Parkes, 1977 – coastal E Brazil from Alagoas S to Rio de Janeiro.
Also Cuba, where probably introduced.

Descriptive notes. 11–13 cm; 11–18·3 g. The largest *Cyanerpes* honeycreeper, both sexes with long (13–25 mm), slender and usually distinctly decurved bill, and red legs (usually duller in female); tail short, but longer than those of other members of genus. Male nominate race breeding is mainly bright purplish-blue, including scapulars, with crown contrastingly azure-blue; lores and large triangular patch on mantle black; upperwing-coverts, upperside of flight-feathers, and tail black; underwing-coverts and undersides of remiges bright yellow (conspicuous in flight); iris dark brown; bill blackish, length rather variable; legs bright red. Male post-breeding ("eclipse" plumage) resembles female, except for black wing and tail feathers, which are not moulted; yellow of underwing also retained throughout year. (In Costa Rica, male acquires eclipse plumage mostly between about Jul and Oct, and for last few months of year almost all adult males are in eclipse; males in some stage of greenish "transition" plumage present in every month except Mar–May, when breeding). Female is dull olive-green above, including crown and nape to rump; dull whitish supercilium rather ill-defined, dusky green lores extending rearwards through eye to form narrow postocular line; tail dusky, tinged and edged olive-green, upperwing-coverts dusky, broadly edged olive-green, flight-feathers and tertials dusky, edged olive-green (tertials with broader pale green edges); side of head light yellow, smudged and narrowly streaked greenish and dusky; throat dull greyish-white, underparts dull light yellow, rather faintly and narrowly streaked greenish, undertail-coverts light yellow; legs dull reddish, brighter during breeding, especially feet. Juvenile male is initially olive-green (including wings and tail), indistinguishable from female except for shorter bill; in next plumage sequence, acquires black wings and tail but retains olive-green female-like plumage (may be retained for extended period of time, as much variation in moult sequence); by end of first year, male shows patches of blue, as do moulting adult males in eclipse plumage. Races differ only minimally, mainly in body size and bill length: *carneipes* is very similar to nominate, but pale blue area on crown of male smaller and more widely separated from black of back, female more yellowish below, especially throat and centre of breast to centre of belly; *gemmeus* is largest race, with heaviest bill, male differs from nominate also in darker blue crown, female greyer (less greenish) above; *eximius* male differs from nominate in decidedly longer, more decurved bill, and blue area on crown paler and slightly larger, extending to nape; *tobagensis* differs from nominate in larger size, including wing and tail (both longer), also bill heavier at base and less decurved, female also darker, less yellowish, below, with green streaking more clearly defined; *brevipes* is smaller than nominate; *dispar* differs in much shorter and thicker bill, pale blue crown shading gradually into darker nape; *violaceus* differs from nominate in wing and tail on average longer, bill on average shorter, and blue colour of male (except cap) more violaceous, female duller yellowish on inner margins of remiges; *pacificus* differs in smaller and darker blue crown patch, also much paler yellow underwing; *gigas* male is much like previous (including pale yellow underwing), but darker and more purplish, female darker and deeper yellow below; *holti* differs from nominate in having pale crown patch reduced in extent, underparts and rear upperparts darker and more intensely coloured. Voice. Rather noisy, often calls constantly, especially when in groups foraging high in trees, but most vocalizations weak, buzzy or lispy and not far-carrying. In Costa Rica, the two commonest calls are high, thin, piercing "tseet" and thin, weak, nasal "chaa", with buzzy meowing quality of a gnatcatcher (*Polioptila*). Scolds with thin, scratchy or buzzy "wee-peew". Rarely heard dawn song a weak "tsip tsip chaa, tsip tsip chaa", repeated over and over for several minutes at daybreak during Feb/Mar–Jun in Costa Rica.

Habitat. Dry to moist and humid areas, where fond of flowering trees at forest edges, coffee and cacao plantations, older second growth, and clearings with numerous tall shady trees; also gallery and riparian woodland, savanna woodland, flowering trees around habitations, and less frequently in canopy of tall moist to humid forest, usually in conjunction with canopy flowering trees. In general, favours drier or more strongly seasonal areas than those occupied by congeners. In Amazonia, commonest in forest and edge habitat on sandy, nutrient-poor soils; curiously rare in or absent from some humid lowlands forests (SE Peru), although presence or absence not always predictable. Sea-level to c. 1000 m in Costa Rica; to 1500 m N of R Orinoco and to 2000 m S of it in Venezuela; to 1100 m in Colombia, to 300 m in Ecuador, and to c. 1000 m in Peru.

Food and Feeding. Mainly fruits and arthropods. Of twelve stomachs examined, eight contained only vegetable matter and two only animal matter, and two contained both; contents included berries, fruit, seeds, caterpillars, ants (Formicidae), ichneumons (Ichneumonoidea) and spiders (Araneae). Other stomachs contained nectar and chalcid hymenoptera. Nestling diet largely fruit, supplemented by insects. In Trinidad, insect-searching accounted for 44% of observed searching,

fruit-eating 44% and nectar-feeding (presumably) at flowers 12%, but proportions may vary seasonally; tiny berries of *Miconia* species comprised 33% of all fruit taken, and arils of arillate fruits and vines accounted for an additional 35% of fruit material eaten in Trinidad. In pairs when breeding, but otherwise found in variably sized, usually single-species groups of up to c. 15 individuals, more rarely much larger groups; regularly forages with mixed-species flocks. Hyperactive, moving nervously through foliage, hopping, flying back and forth, constantly flicking wings, and frequently behaving aggressively towards conspecifics. Forages mostly at middle to upper levels in trees, infrequently descending quite low. In Trinidad, insect-searching occurred at slightly greater heights than did fruit-seeking and insect-hunting. Regularly hangs with head downwards or hangs upside-down to obtain fruit, and hovers to extract arils or to capture insects from foliage. Gleans insects from large branch surfaces by hopping nervously and leaning down to inspect sides or undersides of large branches. Regularly flutters or sallies to capture flying insects; in Trinidad, made up to 40% of insect captures in flight while hovering or sallying. Perches beside flowers and probes them with its bill. Regularly comes to feeders and restaurant dining tables in hotels, taking wide variety of fruit.

Breeding. Reported in May in Mexico, season Feb–Jun in Costa Rica, Feb in Panama, probably Mar–Jul in Trinidad; in Brazil, Sept and Dec in Pará and Oct in Mato Grosso. Nest a small, shallow, thin-walled cup of rootlets, fibres, grass and stems, woven and overlaid with spider webs, usually hidden in branch fork of dense outer foliage 2–14 m (average c. 5 m) above ground, mostly in isolated tree or shrub in pasture or garden, or in plantation or thicket. Clutch 2 eggs, less often 3, white to bluish, speckled with brown, speckling heaviest and forming wreath at large end (old published records of two nests from Trinidad and two from Guyana, described as black fibre pouches suspended above water and containing dark purplish-black eggs, are almost certainly cases of mistaken identity); in Costa Rica, incubation by female, period 12–13 days, chicks fed by both sexes (male participation irregular), nestling period c. 14 days.

Movements. Some local movements, both horizontal and elevational, apparently in response to availability of fruit and nectar, but extent and details of these require documentation. In lowland C Panama sharp swings in abundance of this species believed related to fruit availability. In Costa Rica regarded as a resident, but sporadic and seasonal, especially in areas with marked seasonal differences in rainfall. Seasonal movements occur in N of range, but timing needs documentation.

Status and Conservation. Not globally threatened. Generally common to locally abundant, at least seasonally, over most of range; widespread. Single record from Jamaica probably involved an escaped cagebird. Occurs in numerous protected areas, including Palenque National Park (Mexico), Tikal National Park (Guatemala), Cockscomb Basin Forest Reserve (Belize), Capiro–Calentura National Park (Honduras), Indio-Maíz Biological Reserve (Nicaragua), La Selva Biological Station and Braulio Carrillo and Tapantí National Parks (Costa Rica), Metropolitan, Chagres, Soberanía and Darién National Parks (Panama), Henri Pittier National Park (Venezuela), Los Katíos and Sanquianga National Parks (Colombia). Found widely across most of Amazonian Basin in both protected and unprotected areas, almost none of which is at risk. Isolated Atlantic coastal population is restricted, in large measure, to protected areas.

Bibliography. Genus *CHLOROPHANES* Reichenbach, 1853

169. **Green Honeycreeper**

Chlorophanes spiza

French: Tangara émeraude **German**: Kappennaschvogel **Spanish**: Mielerito Verde
Other common names: Purplish Honeycreeper ("*C. purpurascens*")

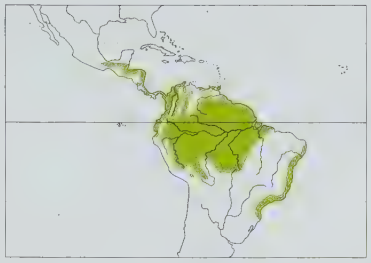
Taxonomy. *Motacilla Spiza* Linnaeus, 1758, Suriname.

Has been placed in family Coerebidae in the past, although more recently in present family on basis of skull morphology. Molecular-genetic data indicate that this species is embedded within the tanagers, but do not support a close relationship to *Dacnis* or *Cyanerpes*; genetic evidence does indicate close relationship to *C. pulcherrimus* (formerly placed variously in *Iridophanes* and *Tangara*). Described taxon *C. purpurascens*, known from one specimen from "Caracas" (Venezuela) and once regarded as a distinct species, now believed to be a hybrid *Chlorophanes* × unknown taxon. Race *guatemalensis* doubtfully distinct; retained pending review. Seven subspecies tentatively recognized.

Subspecies and Distribution.

C. s. guatemalensis P. L. Sclater, 1861 – S Mexico (Gulf–Caribbean slope from Oaxaca and Chiapas) S to E Guatemala, Belize and Honduras.

C. s. argutus Bangs & Barbour, 1922 – extreme E Honduras, E Nicaragua, and on both sides of Costa Rica and Panama S to NW Colombia (N Chocó S to Baudó Mts).



C. s. exsul Berlepsch & Taczanowski, 1884 – SW Colombia (Pacific coast from Valle del Cauca) S to SW Ecuador.

C. s. subtropicalis Todd, 1924 – Colombia (on slopes of all three Andean ranges), Sierra de Perijá, and W base of Andes in Venezuela (Táchira and Mérida).

C. s. spiza (Linnaeus, 1758) – Venezuela (coastal cordillera from Carabobo E to Sucre and N Monagas; E base of Andes from Barinas S to Táchira; and area S of R Orinoco), Trinidad, the Guianas, extreme E Colombia (R Negro–R Guainía) and N Brazil (E from R Uaupés and, S of R Amazon, from middle R Purús E to Pará and coast of Maranhão).

C. s. caerulescens Cassin, 1864 – Colombia (Cauca and Magdalena Valleys, and E base of E Andes from Arauca) S through E Ecuador and E Peru to C Bolivia, and E in WC Brazil to N Mato Grosso.

C. s. axillaris J. T. Zimmer, 1929 – coastal E & SE Brazil (Pernambuco S to Santa Catarina).

Descriptive notes. 13 cm; 14–23 g. Comparatively large honeycreeper with long, slightly decurved and pointed bill. Male nominate race has crown and side of head to point on rear cheek black, rest of plumage shining turquoise-green; upperwing and tail black, wing-coverts, flight-feathers and tail broadly edged greenish; underwing-coverts and thigh sooty black; iris dark red; upper mandible mostly dusky, lower mandible yellow; legs grey. Female is mostly dull green, paler below, throat and centre of belly yellowish; iris red to reddish-brown, lower mandible duller yellow than male's. Immature is much like female, but duller, belly greyish, iris reddish-brown; subadult male, when moulting, may show mottled or patchy plumage of dull green and turquoise, often with variable amount of black on head. Races differ mainly in coloration of male and in size: *guatemalensis* male differs from nominate (and all other races) in predominantly green colour, otherwise essentially identical to nominate, but with slightly shorter bill (some overlap in measurements); *argutus* is similar to previous, but less intensely green; *exsul* male is rather shining green, greener than nominate but not so intensely green as *guatemalensis*, differs from latter also in distinctly shorter bill (15 mm, as against 17·5 mm); *caerulescens* male differs from nominate in predominantly turquoise-blue plumage, more blue than other races; *subtropicalis* male is much like last, but black of crown extends farther rearwards, female differs from nominate in having throat and central underparts yellower; *axillaris* male is similar to nominate, but overall colour more greenish, less bluish, especially on belly, also hindneck lacks yellowish tone usually obvious in nominate, underwing-coverts and thigh paler, light grey (instead of sooty black). Voice. Variety of "tsip" notes and high, sharp "pseet", some calls weak, others loud and buzzy or hissing; may also give fast series of "chip" notes. In Costa Rica male repeats a sharp, dry "tsup" in series of up to 10 notes, possibly as a song.

Habitat. Humid and wet forest, second-growth woodland, wooded and shrubby borders, older second growth, and trees in gardens. Lowlands and foothills to c. 1000 m, smaller numbers higher; to 1400 m in Venezuela, and to 1200 m in Colombia; to c. 1100 m in Ecuador, 1600 m in Peru, and as high as 2300 m in Bolivia.

Food and Feeding. Fruit and arthropods; almost certainly also nectar from flowers and juice from fruits. Of 35 stomachs examined, 23 contained only vegetable matter and four only animal matter, and eight contained both, including fruit pulp, berries, seeds, and flies (Diptera). Stomachs from E Panama (Cana, in Darién) showed a diet fairly evenly balanced between plant and animal matter: one stomach contained bits of two species of *Aphodius* dung beetle, two or more short-tongued bees and fragments of small seeds of *Miconia*; other stomachs contained legs of a dipteran, fragments of a hymenopteran (ichneumonid), four seeds and fragments of drupes. A stomach of a female from C Panama (Cerro Azul) in Feb contained fruit and seeds of *Lasiacis* (a grass that produces berry-like seeds). Nestling diet insects and fruit, including arillate seeds of *Clusia*. In Trinidad, 63% of observed foraging events were for fruit, 22% at flowers, and 15% involved insect-hunting. Of a total of 22 species of fruit taken in Trinidad, c. 50% were of *Miconia* berries, 20% were Ulmaceae and 12% Euphorbiaceae; similar proportion of *Miconia* berries taken in Colombia. In Costa Rica, often noted as eating arils of *Clusia* and catkins of *Cecropia*. Usually observed singly or in pairs or small family groups; regularly comes to fruiting trees, especially when other small frugivores present, but often behaves aggressively and may chase other birds; visits feeding trays in some areas. Forages with mixed-species flocks, in some areas regularly, in other areas mainly as a transient or seasonal member. Restless and nervous-acting, often flicks wings and raises head to watch suspiciously as it forages. In Trinidad, most recorded foraging was 8 m up or higher; majority of insect-searching records were 15 m above ground. Consumes fruit while perched normally, also by hanging head downwards; occasionally in short sallies. Also searched high foliage (14%) and branches and twigs (10%) and sallied to air (20%) in Trinidad.

Breeding. Season Apr–Jul (peak activity May), occasionally as late as Sept, in Costa Rica, with one record of a fledgling being fed in early Nov; recorded May–July in Trinidad; in Panama (Barro Colorado), female gathering nest material in early Jul, and fledglings being fed Jun 11th and Jul 18th. Nest built by female, accompanied by male, a shallow, weakly constructed open cup mainly of small dry leaves, rachises, tendrils and fungal filaments, outer layer of leaves sometimes bound by spider webs (looks like a clump of leaves), one nest 8 cm in diameter and 5 cm in height, with interior dimensions of 5 cm and 2 cm, respectively; placed 1·5–12 m up in tree or shrub at or near edge of forest. Clutch 2 eggs, white, finely speckled with reddish-brown and more thickly marked at large end; incubation by female alone, average c. 80% of daylight hours on eggs, period c. 13 days; chicks fed by both sexes, much more by female (which made more than three times as many nest visits as did male), nestling period c. 12 days.

Movements. Resident. Some very local seasonal shifts may occur in response to availability of fruit and nectar.

Status and Conservation. Not globally threatened. Fairly common to common. Widespread, and found in many parks and other protected areas across its vast range. Populations of some Middle American races, as well as *axillaris* in SE Brazil, are much reduced in size and fragmented because of extensive deforestation, but the species overall is not at risk.

Bibliography. 170. **Golden-collared Honeycreeper**

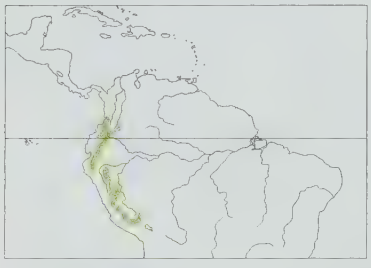
Chlorophanes pulcherrimus

French: Tangara sucrier **German**: Halsbandtangare **Spanish**: Mielerito Collarejo
Other common names: Yellow-collared/Golden-bellied Honeycreeper, Yellow-collared Tanager

Taxonomy. *Dacnis pulcherrima* P. L. Sclater, 1853, "Bogotá".



Has been placed in a monotypic genus, *Iridophanes*, and in *Tangara*, and near various "honeycreepers" because of bill shape and behaviour. Montane distribution mirrors that of many *Tangara* and plum-

age much like that of *Tangara cyanoptera*, although bill shape, bill colour and eye colour differ substantially. Molecular-genetic data indicate that it does not form a monophyletic group with other *Tangara* so far sampled, but is sister-taxon to *C. spiza*. Two subspecies recognized.

Subspecies and Distribution.

C. p. aureinucha (Ridgway, 1879) – Colombia (W slope of W Andes from Valle del Cauca) S to NW Ecuador (Carchi, Esmeraldas and Pichincha).

C. p. pulcherrimus (P. L. Sclater, 1853) – Colombia (head of Magdalena Valley in Huila, and E slope of E Andes from Caquetá) S on E slope through Ecuador and Peru (S to S Cuzco).

Descriptive notes. 11 cm; 14–17 g. Small honeycreeper with thin, sharply pointed bill, bill longer than that of *Tangara*. Male nominate race has head and throat black, sharply set off from narrow yellow-orange nuchal collar and pale underparts; mantle and scapulars black, central mantle blotched pale greenish-straw; lower back to uppertail-coverts pale greenish-straw, rearmost uppertail-coverts black; wing and tail black, upperwing-coverts heavily edged rich cobalt-blue, flight-feathers and tertials edged blue (more broadly on tertials), tail narrowly edged cobalt-blue; underparts shining pale yellowish to greenish opal, whitish on belly; iris red to dark red; upper mandible blackish, lower mandible yellow; legs dark grey. Female is rather different from male, head dull greyish-olive becoming slightly paler greyish-olive on back and rump, narrow yellow-orange nuchal collar inconspicuous; wing-coverts and flight-feathers prominently edged bluish-green; breast and lower underparts dull greyish to yellowish-buff, sides tinged olive. Juvenile dingy brownish-grey, with slightly darker crown and side of head, and weakly marked yellow nuchal collar; immatures recall respective adults, but duller. Race *aureinucha* male differs from nominate in being slightly paler above, with sooty (not black) on head and dark areas of back, nape collar deeper golden, sides and flanks more buffy, bill noticeably longer. Voice. Call a high lisping buzzy "czee" or "psee", sometimes doubled and often given over and over during foraging; call may be lengthened into buzz that rises, then falls, "czeeeéééeee". No song described.

Habitat. Canopy of humid and wet forest, mossy forest borders, older second growth and irregular or disturbed forest in landslides and forest openings. At 1000–1900 m in Colombia; mostly 1100–2000 m in Ecuador (recorded as low as 650 m), and 1100–2000 m in Peru.

Food and Feeding. Recorded as taking berries from *Miconia*, *Cecropia* catkins and nectar; also some insects, but non-quantitative observations suggest that it takes fewer insects than do *Tangara* species. Four stomachs contained vegetable matter, including fruit, seeds and flower petals. Captives accepted fruit, insects and nectar. A restless, nervous-acting species, usually seen singly or in pairs, occasionally in small family parties, seldom in larger groups. Typically, one or two associate with fast-moving mixed-species flocks containing *Tangara*, honeycreepers and other tanagers, and New World warblers (Parulidae). Forages mainly in upper levels of trees; rarely low, even along borders. Moves rapidly along branches and in foliage.

Breeding. In Colombia, male and female carrying food (nest not located) in May in Pialapi Valley (near La Planada, in SW Nariño), pair carrying food in May and another pair with food in Jun at La Planada Reserve; pair with dependent juvenile 26th Sept at Río Ñambí Nature Reserve (SW Nariño), but only female fed young (after foraging for berries in *Miconia* and for insects at *Clusia* flowers); fledgling at end May in W Valle del Cauca. In captivity, builds cup nest; clutch 2 eggs, pale bluish-grey, rusty-brown streaks forming patch at large end, only female incubated, both sexes fed insects to young.

Movements. Some seasonal elevational movements in Colombia, individuals reported down to 1000 m only in May and Jun in upper Anchicayá Valley (Valle).

Status and Conservation. Not globally threatened. Uncommon on E Andean slope; rare on Pacific slope of Colombia and Ecuador. Occurs in Farallones de Cali National Park, Tambito Natural Reserve and probably also Cerro Munchique National Park and El Pangan Nature Reserve (Colombia); may occur also in several protected areas on E slope in Ecuador, e.g. Sangay and Podocarpus National Parks and Cayambe-Coca Ecological Reserve; in Peru, present in Tingo Maria and Manu National Parks. Within this species' range there is also a considerable amount of intact forest that is unprotected, but relatively secure for at least the short term.

Genus *HETEROSPINGUS* Ridgway, 1898

171. Scarlet-browed Tanager

Heterospingus xanthopygius

French: Tangara à sourcils roux **German**: Brauenschopftangare **Spanish**: Tangara Cejirroja

Taxonomy. *Tachyphonus xanthopygius* P. L. Sclater, 1855, "Bogotá".
Molecular data indicate genus is closest to *Hemithraupis* and *Chrysothlypis*. May form superspecies with *H. rubrifrons*; often considered conspecific, but differs in morphology and plumage. Two subspecies recognized.
Subspecies and Distribution.
H. x. xanthopygius (P. L. Sclater, 1855) – E Panama (E Darién, including Tuira valley, Cerro Pirre, Cerro Sapo, Jaqué valley, and Serranía de Jungurudó) and E through N Colombia (along N base of W & C Andes, and S in Magdalena Valley to Antioquia).
H. x. berliozi Wetmore, 1966 – Pacific coast of Colombia (from N Chocó) S to WC Ecuador (Pichincha and Chimborazo).

Descriptive notes. 17 cm; two males 38 g and 39·5 g (*berliozi*). Relatively large, dark tanager with heavy bill slightly hooked at tip. Male nominate race is mainly sooty-black above and below, with bright yellow rump; inconspicuous white line above eye broadens into prominent and slightly raised scarlet postocular tuft; lesser upperwing-coverts bright yellow (often hidden, but may show at bend of wing), rest of wing and tail sooty-black; lower underparts slate-grey; underwing-coverts white, and with elongated white pectoral tuft usually protruding slightly beneath wing; iris dark red; bill blackish; legs dark grey. Female is dark leaden grey from crown to back, rump bright yellow, uppertail-coverts dark grey, tail blackish; lesser wing-coverts yellow (invariably hidden), rest of wing-coverts dark grey, flight-feathers blackish; throat and underparts slightly paler grey than upperparts, white pectoral tuft often visible beneath wing, undertail-coverts tinged yellowish. Juvenile is like female; immature male has dark grey of upperparts gradually replaced by black. Race *berliozi* male differs from nominate in having body plumage slaty, rather than black, female darker than nominate, has white pectoral tufts reduced (less visible). Voice. Infrequently heard song, in W Colombia, a squeaky, twittering and somewhat rhythmic "cheero-bitty cheero-bitty cherro-pit-sup", or other variation consisting of disyllabic and trisyllabic notes repeated over and over, rather weak; sometimes longer song, lasting for several seconds; songs may be given repeatedly with brief pauses between them, or a few random single notes and louder calls interspersed between songs. Frequently heard call a loud, forceful "chip", nasal in quality and often repeated excitedly during foraging with mixed flocks; also thin high "tseet" notes.
Habitat. Tall humid and wet forest, forest borders and tall second growth of various ages, in lowlands and foothills; to c. 900 m in Panama, 1100 m in Colombia and 800 m in W Ecuador.
Food and Feeding. Noted eating *Cecropia* catkins and *Miconia* berries, and in Panama seen to forage around flowers. Contents of one stomach were vegetable matter, of another both vegetable and animal matter; items identified were beetles (Coleoptera), an ant (Formicidae), and seeds of an oleaceous plant. Encountered mostly in pairs, less often singly or in groups of 3–4 individuals that regularly follow mixed-species flocks, especially those with honeycreepers and other tanagers, in canopy and subcanopy; sometimes comes lower along forest borders. In nine observations in Colombia, height above ground of foraging individuals ranged from 5·5 m to 33·5 m. May sit motionless or move sluggishly, perch erect and exposed on treetops for short periods, then peer rapidly at tops of leaves, lunge or peck at prey, sally heavily to foliage, flutter-chase prey in foliage and, after short foraging bout, fly off some distance to another site, leaving slower-moving members of mixed flocks behind. Seen to take *Miconia* berries and *Cecropia* catkins from perch on branch, twigs and petioles.
Breeding. In Colombia, one bird building nest in mid-Dec in upper Anchicayá Valley, pair with begging juvenile on 19th Jan in lower Dagua Valley, and seven birds in breeding condition in Mar–May in NW. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common. Found in variety of second-growth habitats, as well as in humid primary forest. Occurs in several large protected areas, including Darién National Park (Panama), Los Katíos, Ensenada de Utría and probably Sanquianga National Parks (Colombia), and possibly also Awá Forest Reserve and Bilsa Biological Station (Esmeraldas, in Ecuador). Present also in privately operated Reserva El Paujíl (Boyacá), in Colombia. In Ecuador, locally still numerous in Esmeraldas, somewhat less so to S in W Pichincha. This species' range encompasses intact habitat which is not formally protected. Much of this, however, is at risk of deforestation and human settlement, and the species has suffered considerable range contraction and fragmentation in NW Colombia, along N base of W & C Andes, in SW Colombia, and in most of its range in W Ecuador, where it formerly occurred as far S as S Guayas.
Bibliography. Anon. (1983), Angehr *et al.* (2004), Bangs & Barbour (1922), Burns (1997a), Burns & Racicot (2009), Burns *et al.* (2002, 2003), Haffer (1975), Hellmayr (1936), Hilty (1997), Hilty & Brown (1986), Jahn *et al.* (2002), Quevedo *et al.* (2006), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Wetmore *et al.* (1984).

172. Sulphur-rumped Tanager

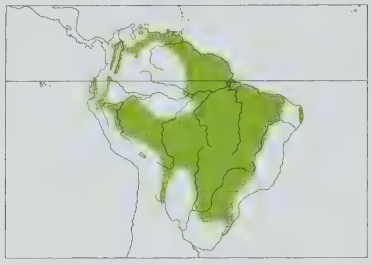
Heterospingus rubrifrons

French: Tangara à croupion jaune **Spanish**: Tangara Lomiazufrada
German: Schwefelbürzeltangare

Taxonomy. *Tachyphonus rubrifrons* Lawrence, 1865, Lion Hill Station, Panama.
Molecular data indicate genus is closest to *Hemithraupis* and *Chrysothlypis*. May form superspecies with *H. xanthopygius*; often considered conspecific, but differs in morphology and plumage. Monotypic.
Distribution. Caribbean slope from Costa Rica (Limón) E to NE Panama (E to Puerto Obaldía, in San Blas); locally on Pacific slope of Panama in Veraguas (sight) and Panamá (Cerro Jefe and Cerro Azul), possibly also in extreme W Darién.

Descriptive notes. 15 cm; 36–40 g. Rather large, dull, heavy-billed tanager, with long bill slightly hooked at tip. Male has head, neck and upperparts to back dark leaden grey, yellow rump (often hidden by folded wings); uppertail-coverts olive-green, tail and upperwing, including coverts, dusky; throat and underparts grey, somewhat paler than above, white pectoral tufts (usually protruding from beneath wing), undertail-coverts olive-green with some admixed yellow; axillaries and underwing-coverts white; iris dark red to reddish-brown; bill blackish; legs blue-grey. Female like male, but may lack olive on uppertail-coverts, and belly often tinged brownish. Immature is similar to adult, but duller, more sooty above and olive-tinged below, wing-coverts edged dull olive, yellow rump patch like adult's but smaller. Voice. Call a thin "tsip" or "tseet", singly or sometimes in rapid, squeaky or twittery series; in flight repeats a thin "seet" or "silt"; in Costa Rica a sharp, buzzy "dzeet", and a higher, thinner "tseet" in flight. Song not recorded.
Habitat. Humid lowland and foothill forest, and forest borders; to c. 700 m in Costa Rica and to c. 900 m in Panama.
Food and Feeding. Fruit, and large and small arthropods. Fruit includes *Cecropia*, *Hamelia*, and mistletoe berries (Loranthaceae). Occurs in pairs and in small family groups, rarely in larger groups (up to 14 seen together). May accompany mixed-species flocks, especially with groups of Black-faced Grosbeaks (*Caryothraustes poliogaster*) and *Tachyphonus delatrii*, and also with mixed groups containing *Tangara* species, honeycreepers and dacnises; also frequently forages away from mixed flocks, in part because of faster speed at which it travels when foraging. Forages in canopy and upper levels, also lower along forest borders. Of 98 observations of foraging, 42% were in treetops, 37% at middle heights and 21% low. Of 24 observed cases of insect-hunting, 50% were from foliage, all from the tops of leaves. Seen to lean downwards to examine sides of branches in Costa Rica.
Breeding. Pair in Nov carrying nest material to epiphyte-covered branch 20 m up. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Central American Caribbean Slope EBA and Darién Lowlands EBA. Uncommon. Inhabits lowlands and foothill regions in Costa Rica from R Reventazón watershed SE along entire Caribbean slope and lowlands to E Panama. Deforestation widespread in unprotected portions of the species' range, and it has disappeared from much of its former range in Costa Rica and W Panama E to Canal Zone area. Occurs in a number of protected areas, including Tapantí National Park and Chirripó/La Amistad International Park (Costa Rica) and portions of La Amistad, Santa Fé, Soberanía and Chagres National Parks and the Comarca Kuna Yala Indigenous Reserve (Panama). Considerable habitat remains along Caribbean slope in Panama E of Canal Zone, and so long as current protected areas are maintained the species' near-term future should be secure.
Bibliography. Carriker (1910), Davis (1972), Garrigues & Dean (2007), Greenberg (1981a, 1984), Greenberg & Gradwohl (1980), Haffer (1975), Hellmayr (1936), Isler & Isler (1999), Leck (1971b, 1972c), Ridgely & Gwynne (1989), Slud (1964), Stiles & Skutch (1989), Wetmore *et al.* (1984), Willis & Eisenmann (1979).

Genus *HEMITHRAUPIS* Cabanis, 1851



173. Guira Tanager

Hemithraupis guira

French: Tangara guira **German**: Guiratangare **Spanish**: Tangara Guirá

Taxonomy. *Motacilla Guira* Linnaeus, 1766, Pernambuco, Brazil.
Molecular data indicate that this genus and *Chrysothlypis* are closely related and probably sister-taxa, and that *Heterospingus* also is closely related to them. This species and *H. ruficapilla* hybridize to some degree in limited zone of contact in SE Brazil, but do not intergrade. Eight subspecies recognized.
Subspecies and Distribution.
H. g. nigrigula (Boddaert, 1783) – locally Venezuela (E of Andes) E to the Guianas and NE Brazil N of R Amazon.
H. g. roraimae (Hellmayr, 1910) – Cerro Roraima region of Venezuela and Guyana.
H. g. guirina (P. L. Sclater, 1856) – Colombia in Cauca Valley (Antioquia S to Valle, once on Pacific slope in Valle), Magdalena Valley and E Andes (W slope from Santander S to Huila, and E slope in at least Boyacá and Cundinamarca and probably S to Caquetá), also Ecuador (W of Andes) and NW Peru (NW Tumbes).
H. g. huambina Stolzmann, 1926 – S Colombia (Nariño), E Ecuador, E Peru and W Brazil (E to R Madeira).
H. g. boliviana J. T. Zimmer, 1947 – E Bolivia, NW Argentina; probably also Mato Grosso, in C Brazil.
H. g. amazonica J. T. Zimmer, 1947 – C Brazil S of R Amazon (between R Madeira and R Tapajós).
H. g. guira (Linnaeus, 1766) – EC Brazil from R Tocantins E to Ceará and S to Goiás and NW Bahia; also extreme NE Brazil from Paraíba to Alagoas.
H. g. fosteri (Sharpe, 1905) – E Paraguay, NE Argentina (Misiones), and interior SE Brazil from Minas Gerais S to Rio Grande do Sul.
Descriptive notes. 13 cm; 9·5–14 g. Rather thin-billed tanager; male resembles oriole (*Icterus*). Male nominate race has crown to nape olive-green, face and throat dark sooty-brown, bordered by long bright yellow supercilium that wraps around behind dark ear-coverts and extends forward to side of throat and narrowly across lower throat; upperparts olive-green (like crown), pale orange-rufous rump; tail dark olive; large patch of rich tawny-rufous across breast, lower underparts yellow, flanks tinged grey; iris brown; bill yellowish, culmen broadly dusky to black; legs leaden-grey. Female is mainly plain olive-green above, with short, weakly indicated yellowish supercilium, narrow yellow

On following pages: 174. Rufous-headed Tanager (*Hemithraupis ruficapilla*); 175. Yellow-backed Tanager (*Hemithraupis flavicollis*); 176. Black-and-yellow Tanager (*Chrysothlypis chrysomelas*); 177. Scarlet-and-white Tanager (*Erythrothlypis salmoni*).

eyering, yellowish rump; mostly yellow below, with flanks tinged grey. Juvenile recalls adult female, but duller, less yellow. Races differ mainly in intensity and extent of yellow surrounding mask of male: *nigrigula* has no yellow across bottom of dark throat, differs from nominate also in darker olive back, supercilium broadly separated from yellow area behind mask, yellow border behind throat patch broader, and breast darker; *roraimae* differs from nominate in having dark face and throat completely bordered by yellow, female darker above and with little yellow on uppertail-coverts; *guirina* differs from nominate in having supercilium narrower and more ochraceous, facial area and throat brownish with yellow border not extending across bottom of throat, and both wing and tail shorter; *huambina* has superciliary stripe brighter yellow than previous and only slightly separated from yellow border on rear of neck; *amazonica* differs from nominate in darker olive back, deeper brownish breast and rump, and usually more prominent yellow behind throat patch; *boliviana* similar to last but larger, back lighter green, rump paler, breast darker brown, yellow band bordering behind ear-coverts usually lacking (rarely pronounced); *fosteri* is most like *amazonica*, but upperparts paler, throat darker (blacker), and no yellow band below black throat. VOICE. Song may vary geographically, or individuals may sing several different songs. Song at dawn in N Venezuela (Aragua) 6–7 sharp, incisive notes, "sa-sit-sit-sit-sit-sit", rather weak; also a series of rapid squeaking and chipping notes reminiscent of *Coereba flaveola*. Dawn song elsewhere a longer, more complex and high "tit-de-de-dit tit tit, tit-de-de-dit tit"; day song a rapid series of nasal "chee" and "chut" notes accelerating into a trill of "chit" notes that may slow at end. Song in Brazil described as a series of high notes that rise slightly, "tsi, tsi, tsi-tseh, tseh, tseh".

Habitat. In Amazonia occurs in canopy of humid *várzea* and *terra firme* forest, as well as in scattered trees in clearings, second growth and older vegetation on river islands. Elsewhere, found in canopy of dry, moist and moderately humid deciduous to semi-deciduous forest, tall second growth and open woodland, shady coffee and cacao plantations, and scattered trees in clearings; also in tall *cerrado* scrub in Brazil, and reported in mangroves in NW Peru. Away from Amazonia, turns up in wide variety of mostly edge habitats and light woodland. Lowlands and hills; sea-level to c. 1450 m in Venezuela, locally to 2000 m in Colombia, to 1100 m in Ecuador and locally to c. 1500 m in Peru.

Food and Feeding. Variety of arthropods, also occasionally small fruits. Observed to consume *Miconia* berries and seen to examine flower corollas for insects. Of 14 stomachs examined, one contained only vegetable matter, eight held only animal matter and five contained both; contents included grasshoppers (Orthoptera), cockroaches (*Blattaria*), caterpillars, bugs (Hemiptera), spiders (Araneae), fruit, and seeds. Pairs or, more often, family groups of 3–7 individuals, rarely groups of up to 25, forage alone or with upper-level or canopy mixed-species flocks dominated by insectivores. Active in high outermost foliage as it hops, bends down, hangs, or flutters to inspect top and bottom surfaces of leaves or to peer beneath twigs for food items; behaviour reminiscent of that of a New World warbler (Parulidae).

Breeding. Reported as breeding in Sept and Oct in Paraguay. Nest a flimsy cup of plant fibres and lichen placed in high fork; eggs white, sprinkled with cinnamon-brown on larger end. No other information.

Movements. Mainly resident. Some may withdraw seasonally from extreme S portions of range in Argentina and S Brazil.

Status and Conservation. Not globally threatened. Widely distributed, but typically uncommon throughout most of range. Occurs in a large number of national parks and other protected areas; in addition, extensive unprotected habitat exists within its range. This species considered unlikely to face any serious threats, except locally where complete conversion of forest and lightly wooded habitats to grasslands.

Bibliography. 174. Rufous-headed Tanager

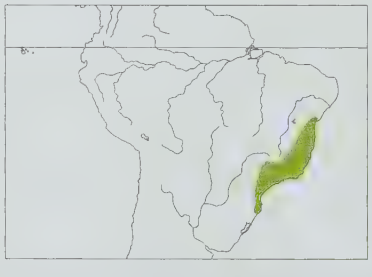
Hemithraupis ruficapilla

French: Tangara à tête rousse **German**: Rostkappentangare **Spanish**: Tangara Cabecirrufa



Taxonomy. *Nemosia ruficapilla* Vieillot, 1818, Rio de Janeiro, Brazil.

Molecular data indicate that this genus and *Chrysothlypis* are closely related and probably sister-taxa, and that *Heterospingus* also is closely related to them. This species and *H. guira* are sister-species; they hybridize to some degree in limited zone of contact, but do not intergrade. Races differ minimally, and species perhaps better treated as monotypic; review warranted. Two subspecies tentatively recognized.

Subspecies and Distribution.

H. r. bahiae J. T. Zimmer, 1947 – SE Bahia, in E Brazil.

H. r. ruficapilla (Vieillot, 1818) – SE Brazil from S Minas Gerais and Espírito Santo S to E Santa Catarina.

Descriptive notes. 13 cm; 11–13 g. Male nominate race has entire crown, side of head and throat rich deep reddish-chestnut, large patch behind ear-coverts and on side of neck bright yellow; large area on chest and spreading onto upper breast orange-rufous (paler than rufous-chestnut of head); nape to back olive with yellowish tinge, rump dark orange-rufous (like chest), uppertail-coverts yellowish, longer uppertail-coverts yellowish-olive; tail feathers dusky, broadly tipped and edged yellow-olive; upperwing-coverts with inner webs dusky, most of outer webs yellowish-olive (like back), rest of wing dusky, flight-feathers heavily edged olive-yellow; mid-breast to mid-belly pale yellow, undertail-coverts paler, sides and flanks olive-grey; iris dark brown; upper mandible blackish-brown, becoming paler near base, lower mandible mostly yellowish; legs dark grey. Female is plain olive-green above, with indistinct short yellowish supercilium, narrow yellow eyering, yellowish rump, mostly yellow below, flanks tinged grey; essentially indistinguishable from female of *H. guira*. Juvenile undescribed. Race *bahiae* is very similar to nominate, but chestnut of crown paler, breast colour paler (most individuals), and wing and tail on average longer. VOICE. Song a rhythmic series of rapid, rattling "chit" notes slowing at end, "chit-t-t-t-t-t-t chew chit-it?", or ending with "...chit, chit, chit", sometimes repeated a dozen times in a minute; similar to dawn song of *H. guira*. Calls are high, slightly grating "enk" and "chit" notes.

Habitat. Forest borders, light woodland, second growth, plantations and shady parks; survives in remnant woodlots as small as c. 250 ha. In area of slight range overlap with *H. guira* in São Paulo, tends to be found in wetter and more heavily forested habitat than that preferred by latter. Sea-level to c. 1500 m.

Food and Feeding. Mostly small arthropods, also small quantities of fruit. Stomachs contained insects. Occurs in pairs, families and small groups, often with mixed-species flocks. Forages in restless, active manner in canopy and upper levels of trees; behaviour like that of *H. guira*.

Breeding. Female carrying nest material into small hole (5 × 8 cm) in hanging clump of *Tillandsia* in Oct. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Locally fairly common. Poorly known race *bahiae* known mostly from Bahia trade skins (provenance of which uncertain). Occurs in many national protected areas in SE Brazil, including Itatiaia, Tijuca, Serra dos Órgãos, Serra da Canastra, Serra do Cipó, Caparaó and Grande Sertão Veredas National Parks, as well as Sooretama and Augusto Ruschi (Nova Lombardia) Biological Reserves. Outside these and other protected areas deforestation is widespread, and little suitable habitat remains. While this species is capable of surviving in small fragmented woodlots, Brazil's scattered reserves and protected areas appear critical as reservoirs for its long-term survival.

Bibliography. Berla (1944), Davis (1945a), Descourtilz (1852), Diamond & Lovejoy (1985), Hellmayr (1915), Isler & Isler (1999), McCarthy (2006), Mitchell (1957), Ridgely & Tudor (1989, 2009), Sazima *et al.* (1993), Sick (1985, 1993), Sick & Pabst (1968), Souza (2002), Willis (1979), Zimmer (1947a).

175. Yellow-backed Tanager

Hemithraupis flavicollis

French: Tangara à dos jaune **German**: Gelbbürzeltangare **Spanish**: Tangara Gorjigualda

Taxonomy. *Nemosia flavicollis* Vieillot, 1818, Cayenne, French Guiana.

Molecular data indicate that this genus and *Chrysothlypis* are closely related and probably sister-taxa, and that *Heterospingus* also is closely related to them. Some races of present species only weakly defined and possibly not worthy of retention, e.g. *insignis* perhaps not distinct from *melanoxantha*; thorough review required. Eleven subspecies currently recognized.

Subspecies and Distribution.

H. f. ornata Nelson, 1912 – Pacific slope from extreme E Panama (E Darién) S to N Chocó, in Colombia.

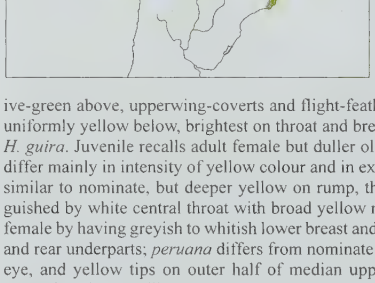
H. f. albigularis (P. L. Sclater, 1855) – N Colombia from R Sinú E to middle Magdalena Valley in Antioquia and Santander.

H. f. peruana Bonaparte, 1851 – E of Andes in Colombia (from Meta) S through E Ecuador to Peru N of R Marañón and R Amazon (Amazonas and Loreto).

H. f. aurigularis Cherrie, 1916 – SE Colombia, S Venezuela (S of R Orinoco), and N Brazil (in upper R Uaupés and R Negro).

H. f. hellmayri Berlepsch, 1912 – SE Venezuela (E Bolívar) and W Guyana (Merumé Mts).

H. f. flavicollis (Vieillot, 1818) – Suriname, French Guiana and NE Brazil (N of R Amazon).



H. f. obidensis Parkes & Humphrey, 1963 – N bank of lower R Amazon in Brazil.

H. f. sororia J. T. Zimmer, 1947 – N & E Peru S of R Marañón.

H. f. centralis (Hellmayr, 1907) – SE Peru, N & C Bolivia and SC Brazil (E to N Mato Grosso).

H. f. melanoxantha (M. H. C. Lichtenstein, 1823) – coastal E Brazil (Pernambuco and Bahia).

H. f. insignis (P. L. Sclater, 1856) – SE Brazil (Espírito Santo and Rio de Janeiro).

Descriptive notes. 13 cm; 11–15 g. Relatively slender-billed tanager. Male nominate race is mainly brownish-black above, with bright yellow lower back, rump and uppertail-coverts, longer uppertail-coverts brownish-black; tail and almost entire wing brownish-black, narrow band of white on outer web of outer primaries (showing as small white patch at base of primaries); throat and foreneck bright yellow, underparts off-white, sides tinged grey (sometimes with small amount of black mottling on sides), undertail-coverts bright yellow; iris dark brown; upper mandible dusky, lower mandible pinkish to yellow; legs dark grey. Female is olive-green above, upperwing-coverts and flight-feathers darker, edged yellowish-green; more or less uniformly yellow below, brightest on throat and breast, with flanks tinged olive; similar to female of *H. guira*. Juvenile recalls adult female but duller olive above and duller, dingy yellow below. Races differ mainly in intensity of yellow colour and in extent of black mottling on sides of male: *ornata* is similar to nominate, but deeper yellow on rump, throat and undertail-coverts; *albigularis* is distinguished by white central throat with broad yellow malar, prominent black spotting on side of chest, female by having greyish to whitish lower breast and belly, with yellow only from throat to mid-breast and rear underparts; *peruana* differs from nominate in short yellow supraloral line, yellow arc below eye, and yellow tips on outer half of median upperwing-coverts (forming tiny yellow wingbar); *aurigularis* is much like nominate, but with more extensive black mottling on side of breast; *hellmayri* is distinguished by yellow on throat extending well down onto central breast, and with side of chest densely mottled black; *obidensis* differs from nominate in duller, more brownish-black, upperparts and in having yellow of rump, throat and undertail-coverts less intense, female paler and more greenish above and below; *sororia* is much like *aurigularis*, but male has throat paler yellow; *centralis* is much like nominate, but somewhat larger, side of chest more scalloped and barred, back deeper black, throat paler yellow (about the same as *peruana*); *melanoxantha* is slightly larger than nominate, but male otherwise essentially identical, female brighter, extensively yellow below; *insignis* is slightly larger than nominate, but male essentially identical to previous, female decidedly browner above than female of previous. VOICE. During foraging, often constantly repeats sharp, forceful and high-pitched "tsick" and "tsuk" and "tsu-dik"; in Peru described as a rich "chew" and a higher-pitched "tsew" and "seew". Song, in Brazil, "si, si, si, si...", insect-like; song, in E Ecuador (agitated bird) a rapid, almost frantic, buzzy "tissz, tz-tz-tz, tuck", fairly high-pitched, repeated over and over.

Habitat. Found mainly in tall humid *terra firme* and, to lesser extent, in *várzea* forest; somewhat less frequently along forest borders or in shady plantations and trees in clearings. Lowlands and

hills; to c. 950 m in Venezuela, to 1000 m in Colombia, and to c. 700 m and 750 m in Ecuador and Peru, respectively.
Food and Feeding. Arthropods and fruit. Reported to eat fruit of melastomes, myrtle (Myrtaceae) and *Urtica*. In Peru, at least 30% of observed foraging records involved fruit. Of twelve stomachs examined, three contained only vegetable matter, six held only animal matter and three contained both; contents included insect parts, a small orthopteran, berries and fruit. Contents of other stomachs were beetles (Coleoptera), cockroaches (*Blattaria*), caterpillars, and a leafhopper (Homoptera). In pairs and family parties, almost always with canopy or upper-level mixed-species flocks of insectivores and frugivores, with which, over much of range, it both forages and rests. Behaves as a nuclear species in mixed flocks in E Brazil; in SE Peru mainly a transient in mixed flocks. Like congeners, restless, active and alert. Forages in upper levels of canopy and in emergent trees, where it rapidly searches top and bottom surfaces of leaves, especially clusters of terminal foliage; techniques are perch-gleaning, less often reaching or hanging downwards, occasionally fluttering or hovering, or sallying short distances to air.
Breeding. In Colombia, pair building nest on 27th Sept in upper canopy on forested ridge at La Fiebre (middle Magdalena Valley), also ten birds in breeding condition in Apr–Jun and one in Jan in N. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common. Has a large range that includes portions of lowland E Panama and adjacent N Colombia, as well as much of the Guianan region and Amazonia, and isolated population along Atlantic coast of Brazil. Occurs in many protected areas, and vast areas of appropriate habitat lie in unprotected areas within its range. Populations inhabiting Panama–NW Colombia region (races *ornatus* and *albigularis*) and SE Brazil coastal corridor (*melanoxantha* and *insignis*) live in areas that are heavily deforested, and relatively little habitat in these regions has any kind of protected status. Establishment of additional protected reserves in these areas would benefit not only these populations, but also other species. Among the protected sites where this tanager occurs in SE Brazil are Sooretama and Poço das Antas Biological Reserves and Tijuca and Serra dos Órgãos National Parks.
Bibliography. Burns (1997a), Burns & Racicot (2009), Burns *et al.* (2002, 2003), Descourtilz (1852), Diamond & Lovejoy (1985), Greenberg (1981a), Haverschmidt & Mees (1994), Hennessey (1998), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Mee *et al.* (2002), Mitchell (1957), Moore *et al.* (2009), Munn (1985), Parker & Goerck (1997), Parkes & Humphrey (1963), Pearson (1971, 1975b), Ridgely & Greenfield (2001a, 2001b), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Sick (1985, 1993), Snethlage (1914), Snyder (1966), Souza (2002), Stiles *et al.* (1999), Wetmore *et al.* (1984), Willis (1977), Zimmer (1947a).

Genus *CHRYSOTHLYPIS* Berlepsch, 1912

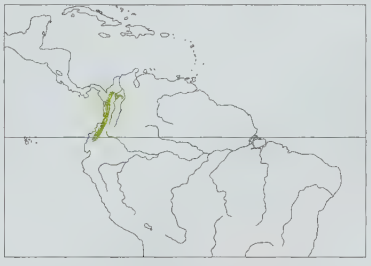
176. Black-and-yellow Tanager

Chrysothlypis chrysomelas

French: Tangara loriot **German**: Zitronentangare **Spanish**: Tangara Negriamarilla

Taxonomy. *Tachyphonus chrysomelas* P. L. Sclater and Salvin, 1869, Cordillera del Chucú, Veraguas, Panama.
Molecular data indicate that this genus and *Hemithraupis* are closely related and probably sister-taxa, and that *Heterospingus* also is closely related to them. Three subspecies recognized.
Subspecies and Distribution.
C. c. titanota Olson, 1981 – Caribbean slope of N Costa Rica from Alajuela (vicinity of Cerro Santa Maria) S along E base of Cordillera Central and Cordillera de Talamanca to area of Panama border.
C. c. chrysomelas (P. L. Sclater & Salvin, 1869) – W Panama (W Chiriquí E to vicinity of Cerro Campana, in W Panamá).
C. c. ocularis Nelson, 1912 – E Panama from Cerro Jefe (and Pacific slope in E Panamá and Darién) E to extreme NW Colombia (Cerro Tacarcuna).

Descriptive notes. 12 cm; 11–15 g. Small, parulid-like tanager with fairly thin, sharply pointed bill; male plumage distinctive. Male nominate race is bright yellow, except for narrow black ocular ring and jet-black hindneck and mantle, upper back, wing and tail; iris brown; bill black; legs blackish. Female has head and entire upperparts, including upperwing-coverts and tail, greenish-olive, flight-feathers dusky, edged greenish-olive; yellow below, sides and flanks tinged olive-green, undertail-coverts yellowish, underwing-coverts white, and may show tuft of white beneath wing; legs greyish-green. Immature male is much like female, but brighter yellow below, upperwing-coverts with paler edges. Race *ocularis* is very like nominate, but male loral area partly black (not entirely yellow), possibly has larger black ocular ring, female brighter, more uniform greenish-yellow below; *titanota* male is identical to nominate, female differs from nominate female in having greyish flanks, and throat and belly mainly white with only a diffuse yellowish band across breast. Voice. Call a sharp, sibilant "tsee" or "tseeeut" like that of a hummingbird (Trochilidae), singly, doubled or followed by several shorter notes, e.g. "tsew tsu-tsu-tsu"; often calls in flight. Song apparently unrecorded.
Habitat. Canopy of humid and wet foothill forest, forest borders and adjacent tall second growth; much less frequently in scattered trees in humid clearings or in low shrubs. At 350–1600 m.
Food and Feeding. Arthropods and fruit; noted as taking *Miconia* berries. Contents of 13 stomachs were vegetable matter only, three others included vegetable and animal matter; contents included fruit, *Cecropia* seeds, caterpillars, ants (Formicidae), and orthopterans. Occurs in pairs and in small groups of 3–6 individuals, typically associated with mixed-species flocks of insectivores and frugivores. Sprightly and restless, rapidly gleaning small arthropods from outer foliage of high trees. Foraging movements diverse, and include gleaning, sallying for and flutter-chasing after escaping prey, reaching or hanging from twigs, hovering at surface of large leaves, and probing dead leaves.
Breeding. One nest found in Jun in Costa Rica: a neat cup of fine rootlets, lined with black fungal rhizomorphs, with middle layer of small dead leaves and outer layer of green moss, placed 8 m up near tip of *Inga* branch. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Central American Caribbean Slope EBA and Darién Lowlands EBA. Uncommon to locally fairly common. Presence in Colombia (race *ocularis*) based on specimen from near Cerro Tacarcuna. Although this species has a fairly small range, its global population is believed to be well above the level applicable for inclusion on the Red List. Occurs in several protected areas, including Braulio Carrillo National Park, Río Pacuare and Hitoy Cerere Biological Reserves and La Amistad International Park (Costa Rica), La Amistad, Santa Fé, Soberanía, Chagres and Darién National Parks (Panama), and Los Katíos National Park (NW Colombia). While the species remains fairly common in some foothill forested areas, its range is increasingly fragmented, especially in Costa Rica and W Panama, where large areas of lowland and foothill forest have been converted to agricultural purposes, e.g. bananas and cattle, and are being lost to expanding human settlement.
Bibliography. Athanas (2004), Burns (1997b), Burns *et al.* (2003), Carriker (1910), David & Gosselin (2002a), Davis (1972), Foster & Johnson (1974), Garrigues & Dean (2007), Greenberg (1981a), Isler & Isler (1999), Marín & Schmitt (1991), Olson (1981c), Parker *et al.* (1985), Remsen *et al.* (2010), Ridgely & Gwynne (1989), Robbins *et al.* (1985), Slud (1964), Stiles & Skutch (1989), Strauch (1977), Wetmore *et al.* (1984).



Genus *ERYTHROTHLYPIS* Berlepsch, 1912

177. Scarlet-and-white Tanager

Erythrothlypis salmoni

French: Tangara rouge **German**: Seidenflankentangare **Spanish**: Tangara Rojiblanca

Taxonomy. *Dacnis salmoni* P. L. Sclater, 1886, Remedios, Antioquia, Colombia.
Originally described in genus *Dacnis*, then transferred to *Nemosia*, and later placed in present monotypic genus. More recently, has been included within *Chrysothlypis* by some, but plumage very different, and the two also differ substantially in behaviour and in some morphological features; provisionally retained in monotypic genus. Thorough review of relationships, including molecular analysis, is warranted. Monotypic.
Distribution. N base of W & C Andes of Colombia (Antioquia S to middle Magdalena Valley) S on Pacific coast and slope to NW Ecuador (Esmeraldas).

Descriptive notes. 12 cm; male 9·8–14·5 g. Comparatively thin tanager, male with highly distinctive plumage. Male has head, throat and entire upperparts scarlet, lesser and median upperwing-coverts red (darker than body plumage), greater coverts and primary coverts dusky, broadly edged red, flight-feathers and tertials brownish-black, edged red, wingtips black (no edging); tail feathers tinged brownish and edged red; narrow median stripe down breast and belly scarlet, rest of underparts white, undertail-coverts red; iris brown; upper mandible dusky, lower mandible pale yellow; legs greyish-horn. Female is very different from male, bronzy olive-brown above, wing-coverts and flight-feathers dusky, edged brownish-olive (wing looks brownish-olive), primary coverts dusky; tail dark brown, edged olive; throat and chest tinged yellowish-buff, often a hint of yellowish-buff on median line of breast in pattern similar to that of male; rest of breast, and especially sides and flanks, whitish. Immature male is much like female, and probably indistinguishable from it; subadult male olive like female, but with patches of red showing. Voice. Possible song a weak, high-pitched and relatively short "ti ti ti-te-te-taheét", variable in length; undistinguished and easily overlooked, except for somewhat stronger note at end. During foraging or flying a weak, sibilant "chip" or "sciip".
Habitat. Borders and openings in foothills where there is stunted second growth, and especially dense, stunted or low mossy woodland along foggy ridgetops, on steep canyon slopes, and around steep, mossy, regenerating landslide scars; in areas of tall wet forest mainly at openings, light-gaps and in disturbed areas where vegetation is shorter with dense mossy regrowth. From c. 25 m to 1200 m, but uncommon and local in lowland areas, e.g. around Bahía Solano (Chocó), in Colombia; more numerous above c. 300 m in foothill regions.
Food and Feeding. Fruit and arthropods. In study in W Valle (Colombia) 58% of observed feeding records involved fruit, the remainder insects and other small arthropods. At least 11 species of fruit recorded in diet; 51% of all records were of arillate fruits, e.g. *Tovomitopsis* (Guttiferae) and *Clusia*, and a further 36% were of *Miconia* berries. Found in pairs, in family parties and in small groups of up to about six individuals, foraging alone or with mixed-species flocks containing other tanagers, especially *Tangara*. Forages actively, gleaning in outer foliage, hanging from leaves, and hovering. In W Valle, arthropod prey taken in crown of shrubs and trees, mostly 4·5–15 m up, rarely below 3 m. Of insect-hunting records, 61% of captures were made by gleaning, reaching or quick darting movements, mostly to foliage, more rarely from small branches (less than 3 cm in diameter), leaf petioles, flowerheads and fruit surfaces; 23% of captures made during sallies to air or flutter-pursuits, 8% during hovering and 7% by sallying to leaves and flowers. Often obtains arillate fruits by hovering. Gulps small berries, pecks pieces from larger items.
Breeding. Stub-tailed fledglings seen in Apr and May. Young of a previous generation may assist at the nest. No other information.
Movements. Resident. No local or migratory movements recorded during 16-month study with ringed birds in R Anchicayá, in Valle del Cauca (Colombia).
Status and Conservation. Not globally threatened. Restricted-range species: present in Nechí Lowlands EBA and Chocó EBA. Uncommon to locally fairly common. Occurs in several protected areas in Colombia, including Los Farallones de Cali, Ensenada de Utría and Tatamá National Parks, possibly also Sanquianga National Park and one or more protected areas in SW Colombia; has been found also in the newly established and privately operated La Reserva Arrierito Antioqueño (in N Antioquia), and occurs within the upper Anchicayá Valley, which is a privately protected hydropower watershed. Range includes extensive areas of habitat that are not protected but remain mostly intact. Deforestation is widespread and expanding throughout range, especially in foothills, including in NW Ecuador, and the species can be assumed to be declining. Because it readily utilizes landslides and other disturbed sites on steep slopes, however, it may not face immediate risk.

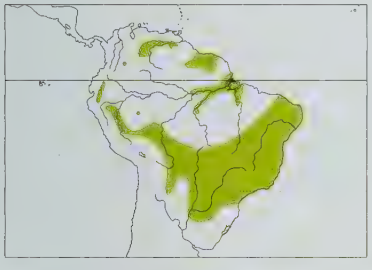
Genus *CONIROSTRUM*



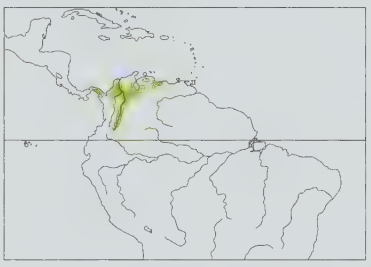
d'Orbigny & Lafresnaye, 1838

178. Chestnut-vented Conebill

Conirostrum speciosum

French: Conirostre cul-roux **German**: Rotsteiß-Spitzschnabel **Spanish**: Conirrostro Culirrufo

Taxonomy. *Sylvia speciosa* Temminck, 1824, Rio de Janeiro, Brazil.
Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. This species was originally placed in genus *Ateleodacnis*, and some taxonomists argue that it, along with the other lowland conebills (*C. leucogenys*, *C. bicolor* and *C. margaritae*), should be returned to that genus; as a group they are morphologically quite distinct from most highland members of present genus. Three subspecies recognized.
Subspecies and Distribution.
C. s. guaricola Phelps, Sr & Phelps, Jr, 1949 – E Guárico and W Anzoátegui, in NE Venezuela.
C. s. amazonum (Hellmayr, 1917) – E of Andes in W Venezuela (Apure) and E Colombia (S to Meta and N Vichada); E Ecuador and E Peru; and C Guyana E to N French Guiana, and N Brazil (NE Roraima, E Amazonas and W, C & NE Pará).
C. s. speciosum (Temminck, 1824) – SE Peru and Bolivia (except W) E across SC Brazil (to Maranhão, S to Mato Grosso, Paraná and São Paulo), Paraguay and NW & NE Argentina (Jujuy; E Formosa, N Corrientes and Misiones).



Descriptive notes. 11 cm; 8–9 g (Argentina). Small, rather dark conebill. Male nominate race has head and upperparts rather dark greyish-blue, lores and subocular area paler ashy grey, becoming whitish on lower (sometimes also upper) eyelid; lesser and median upperwing-coverts dark blue-grey, greater coverts dusky, broadly edged blue-grey; primary coverts blackish, flight-feathers, tertials and tail dusky, edged blue-grey, sometimes a small whitish patch at base of outer primaries; throat and underparts slightly paler, more bluish-grey, becoming greyish-white on belly; undertail-coverts contrastingly chestnut; iris dark reddish-brown; bill blackish; legs dark grey. Female has bluish-grey crown and nape, indistinct and variable whitish supraloral line, sometimes extending into weak supercilium, olive-green upperparts, including wings and tail; throat and underparts, including undertail-coverts, dull greyish-white, tinged with variable amount of buff. Juvenile is like female but duller, with head olive (like back). Races differ mainly in darkness of plumage, nominate palest (especially below); *amazonum* is close to nominate, but lores and subocular area blue-grey like rest of head (not paler) and underparts darker, female also slightly darker overall than nominate female; *guaricola* is intermediate in plumage colour between previous and nominate, and usually has tiny white spot at base of primaries. Voice. Song, in Venezuela, a very high, thin "tidé, tidé, tidé, tidé, ti'dee'rít" at leisurely pace, weak and easily overlooked; in Peru described as a series of repetitive phrases composed of high, squeaky notes, e.g. "tsip'er-tséé tsip'er-tséé tsip'er-tséé...", like that of a hummingbird (Trochilidae) in pattern and quality; in NE Brazil (Ceará) a repetitive, high-pitched "sa-séét, sa-séét, sa-séét..." at about one phrase per second for up to 15 seconds or longer. Calls include "tic" and "ti" notes during foraging.
Habitat. In Venezuela mainly in dry strongly seasonal areas, where occurs in canopy of gallery forest and treetops in scattered open groves of large trees, e.g. *Pithecellobium* and Leguminosae/Mimosoideae. In Ecuador found in canopy and borders of humid forest and secondary woodland, mainly in or near foothills. Local along R Amazon and its tributaries in canopy of fairly young successional-stage vegetation, including *Cecropia*, *Inga*, *Ficus* (figs), *Gynerium* cane, and Mimosoideae, on river islands and *várzea* riverbanks. In S Brazil and N Argentina found in dry open woodland and disturbed areas with taller trees. In all areas favours woodland where Leguminosae/Mimosoideae with small pinnately compound leaves predominate (e.g. *Pithecellobium*, *Albizia*). Sea-level to c. 200 m in Venezuela; c. 400–1200 m in Ecuador; to c. 600 m (rarely 900 m) in Peru; to 1300 m or possibly more in SE Brazil.
Food and Feeding. Diet little known; insects, possibly nectar. Seen in pairs and in families of 3–5 individuals; in SE Ecuador up to six seen together. Occurs with small mixed-species flocks or alone about equally; in SE Peru noted as foraging in association with Buff-fronted Foliage-gleaner (*Philydor rufus*) and *Ramphocelus carbo*. Active and full of nervous energy, but easily overlooked as it forages high in small leaves of outer foliage of spreading branches. Especially fond of searching tiny leaflets and axils of doubly compound foliage of legumes (Leguminosae), busily hustling from one spray of leaflets to the next, often hanging upside-down to probe and glean. May also use or key on damaged leaves locally. In SE Ecuador seen to forage in flowering trees, possibly taking insects or nectar.
Breeding. No information on season. Nest in E Brazil (Minas Gerais) a tiny cup made from leaf petioles and fibres, hidden in curled dead *Cecropia* leaf hanging from thin vine 4·5 m up at edge of forest bordering a road (nest differed from that of some congeners in being built from plant material, rather than animal product such as horsehair, feathers); contained 3 eggs, bluish-green with brown spots, dimensions 16·3–17·4 × 12–12·6 mm. No other information.
Movements. Resident. No certain local or migratory movements known.
Status and Conservation. Not globally threatened. Widespread, in varying abundance. Uncommon in Venezuela; rare and local in Ecuador; uncommon and local along R Amazon river and its tributaries. Can be found in a number of large protected areas, including Manu National Park (Peru), Calilegua and Iguazú National Parks (Argentina) and Poço das Antas Biological Reserve and Amazonia, Tijuca and Iguaçu National Parks (Brazil). Because this species occurs in a wide variety of secondary, disturbed and open woodland situations, as well as in areas where the impact of human settlement is often small, it is to a considerable extent secure against near-term or longer-term risks.
Bibliography. Albano (2006), Beecher (1951a), Burns (1997a), Burns & Racicot (2009), Burns *et al.* (2002, 2003), Fjeldså & Krabbe (1990), Hellmayr (1935), Hilty (2003), Hilty & Brown (1986), Lovette & Bermingham (2002), Lysinger *et al.* (2005), Marantz & Zimmer (2006), Meyer de Schauensee (1970a), Narosky & Di Giacomo (1993), Naumburg (1930), Oren & Parker (1997), Pacheco *et al.* (2007), de la Peña & Rumboll (1998), Ribon & Simon (1997), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Ridgway (1902), Salaman *et al.* (2002), Schulenberg *et al.* (2007), Sick (1985, 1993), Snyder (1966), Souza (2002), Tostain *et al.* (1992), Zimmer (1942a).

179. White-eared Conebill

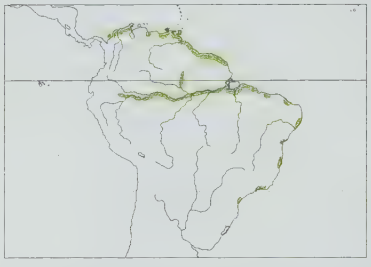
Conirostrum leucogenys

French: Conirostre oreillard **German**: Weißohr-Spitzschnabel **Spanish**: Conirrostro Orejiblanco

Taxonomy. *Dacnis leucogenys* Lafresnaye, 1852, Bogotá, Colombia.
Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. This species was originally placed in genus *Ateleodacnis*, and some taxonomists argue that it, along with the other lowland conebills (*C. speciosum*, *C. bicolor* and *C. margaritae*), should be returned to that genus; as a group they are morphologically quite distinct from most highland members of present genus. Three subspecies recognized.
Subspecies and Distribution.
C. l. panamense (Griscom, 1927) – E Panama (from Gulf of San Miguel E to Darién) and NW Colombia (Sinú Valley in Córdoba).
C. l. leucogenys (Lafresnaye, 1852) – N Colombia (Sucre, Atlántico, Magdalena and Cesar, and S in Magdalena Valley to Huila; E of Andes in Catatumbo lowlands of Norte de Santander) and adjacent W Venezuela (E across Zulia, Falcón and Yaracuy to Carabobo, in coastal cordillera).
C. l. cyanochroum (Todd, 1924) – W Venezuela in foothills of Sierra de Perijá and W base of Andes (Mérida).

Descriptive notes. 9·5 cm; c. 7 g. Small, short-tailed conebill with thin, sharply pointed bill. Male nominate race has crown and nape shiny black, contrasting white cheek and ear-coverts; upperparts dark bluish-grey, narrow white rumpband (usually hidden by closed wings); entire upperwing and tail dusky blue-grey; throat to belly pale grey with bluish tinge, centre of belly white, undertail-coverts chestnut; iris dark brown; bill black; legs dark grey. Female is dull bluish-grey above, with narrow, inconspicuous whitish rump; lores, narrow eyebrow, side of head and underparts pale buff (has rather pale, "blank" face), breast with olive tinge, belly with yellowish tinge. Juvenile male is plain brownish-grey above, and lacks white ear patch. Race *panamense* male differs from nominate in having decidedly darker plumage above and below, female also darker above and less olive; *cyanochroum* male is much like nominate, but slightly darker above and darker grey on breast, female more olive tinged on underparts and with little yellow. Voice. Song a high, thin, tinkling series of notes, "tsing-le, tséet-e-tséet" or similar variant, usually short, occasionally longer, to c. 1·5 seconds, complex, unmusical, and often slowing or fading at end. Often sings persistently, but easily overlooked.
Habitat. Dry to moist (semi-deciduous), open woodland, wooded borders, cacao plantations, gallery forest, and scattered tall spreading legumes in pastures; also in moist to humid evergreen forest and young to older second growth, especially where there are large legume trees. Sea-level to c. 800 m; once to 1300 m in Falcón, in Venezuela.
Food and Feeding. Few data on diet; arthropods and nectar taken. Lively pairs or parties of 3–5 individuals; sometimes with small mixed-species flocks. Sedulously gleans minute prey in high outer foliage of legumes and other medium-sized to tall trees with compound or pinnately compound leaves. Often hangs upside-down from leaves to check for minute insects or other arthropods. Sips nectar from *Erythrina* flowers, especially in dry season; may then come lower or to small trees, but otherwise usually remains high and easily overlooked. Foraging behaviour much as that of *C. speciosum*.
Breeding. In Colombia, pair building nest in Jan in upper Magdalena Valley (in Huila) and birds in breeding condition in Jan, Apr and May in N. No other information.
Movements. Resident.
Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Can be found in a few protected areas, including El Paujil Reserve (Colombia) and in or near Morrocoy National Park and probably also Terepaima National Park (Venezuela). Thrives in a variety of second-growth habitats so long as there are scattered tall legumes or other open trees (especially with small compound leaves) along wooded borders or in pastures.
Bibliography. Beecher (1951a), David & Gosselin (2002a), Davis (1972), Hellmayr (1935), Hilty (2003), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Miller (1947), Quevedo *et al.* (2006), Ridgely & Gwynne (1989), Ridgely & Tudor (1989, 2009), Ridgway (1902), Schäfer & Phelps (1954), Zimmer (1942a).

180. Bicolored Conebill



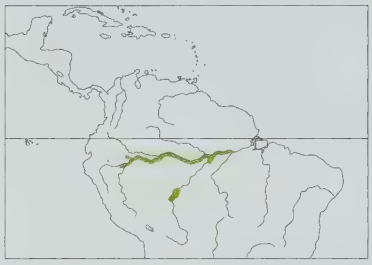
Conirostrum bicolor

French: Conirostre bicolore **German**: Zweifarben-Spitzschnabel **Spanish**: Conirrostro Bicolor

Taxonomy. *Sylvia bicolor* Vieillot, 1809, Cayenne, French Guiana.
Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. This species previously placed in *Ateleodacnis*, and some taxonomists argue that, along with the other lowland conebills (*C. speciosum*, *C. leucogenys* and *C. margaritae*), it should be returned to that genus; as a group they are morphologically distinct from most highland members of present genus. Two subspecies recognized.

On following pages: 181. Pearly-breasted Conebill (*Conirostrum margaritae*); 182. Cinereous Conebill (*Conirostrum cinereum*); 183. Blue-backed Conebill (*Conirostrum sitticolor*); 184. Capped Conebill (*Conirostrum albifrons*); 185. Rufous-browed Conebill (*Conirostrum rufum*); 186. Tamarugo Conebill (*Conirostrum tamarugense*); 187. White-browed Conebill (*Conirostrum ferrugineiventre*).

Subspecies and Distribution.
C. b. bicolor (Vieillot, 1809) – Colombia from SW of Cartagena (Fuerte I) E along coast, including Margareta I and Trinidad, locally to N & E Brazil (Amapá, and mouth of R Amazon, E then S very locally to São Paulo); also locally along R Branco (NC Brazil).
C. b. minus (Hellmayr, 1935) – both banks of R Amazon in NE Peru, SE Colombia and Brazil E to vicinity of R Madeira and R Tapajós, and probably (records spotty) to near mouth of R Amazon.



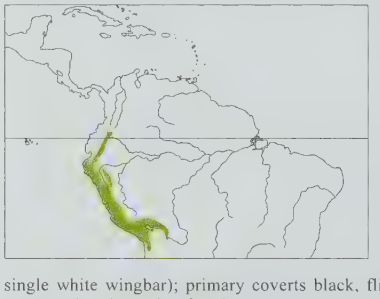
Descriptive notes. 11·4 cm; 10·5–11 g. Small dull, bluish-grey conebill with thin bill. Male nominate race has crown, nape and upperparts, including upperwing-coverts, dull pale bluish-grey, tail blue-grey, flight-feathers dusky, inner ones and tertials edged pale bluish-grey; lores and facial area pale grey, becoming dingy pale greyish-buff below, with throat and lower underparts palest; iris dull orange-red to dark red; bill bluish-grey; legs dull greyish-pink. Female is similar to male or slightly duller; underparts pale greyish-buff. Immature is dull olive above, including crown, nape, back and rump, and distinctly yellowish below, brighter on throat and breast, but amount of yellow variable; iris dark red, more or less as that of adult. Race *minus* differs from nominate in decidedly smaller size, rufescent tinge on underparts, especially undertail-coverts, and slight rufescent (not greyish) tinge on ear-coverts. Voice. Infrequently heard song in coastal Venezuela a high-pitched, squeaky and somewhat buzzy "pfits, t'wit'wit'wit'chit" or similar; in coastal mangroves of Brazil varies from short 2-note or 3-note phrases to much longer, complex, squeaky and fussy songs, e.g. "tzúu'eet, ..." repeated over and over (first note strongly emphasized) or much more complex "tsit-péu, tsit'tsit'pee'pee, zuu, tsit'tsit...", rather jerky and sputtering; in inland Brazil described as "tséédi, tséédi-didelide, tséédi, léédi'léé-zrrr". At least in some areas reminiscent of songs of *Coereba flaveola*, and everywhere much shorter than and quite unlike longer and much faster songs of *C. margaritae*. Soft calls, during foraging, include high, sibilant "tsik", also "pit-sik" and "few-it-sip".
Habitat. Found in two distinct habitats: first, on N coast, occurs locally in mangroves (red, black, white, etc.), and sometimes in adjacent low flooded forest (but always near mangroves and closely associated with them); second, along R Amazon and a few of its major tributaries, found in shrubby younger successional stages of vegetation on river islands and riverbanks. Sea-level to c. 100 m. In coastal mangroves from Colombia E to the Guianas generally not found together with resident "chestnut-headed" races of Yellow Warbler (*Dendroica petechia*), one or the other species (but not both) occurring in mangrove sites, although exact nature of possible competitive interactions between these two species is not well understood; present species is, however, found together with migrant Yellow Warblers in mangroves.
Food and Feeding. Diet poorly known; small arthropods taken. Occurs in pairs and family parties; usually not with mixed-species flocks, although occasionally loosely associated with a few other species in mangroves. Keeps in middle to upper levels of foliage, occasionally down to eye level, as it peers and probes into tight clusters of small leaves. Busily gleans for small arthropods in foliage and twigs of shrubs and trees on river islands; on river islands may use damaged leaves of *Cecropia*. Searches leaf surfaces (possibly the upper surfaces more) in mangroves. Easily attracted to source of squeaking noises, and will often closely approach a human observer.
Breeding. Season Feb–May in N Colombia (La Guajira). in N of range, nest a small, compact, deep cup of grass mixed with feathers, placed 0·3–4 m up in fork of mangrove branch. Clutch 2 eggs, pale buff with dark brown blotches, mainly at larger end. Nests in Trinidad often parasitized by Shiny Cowbird (*Molothrus bonariensis*). May breed in immature plumage. No further information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common locally in coastal N portion of range; uncommon and very local in Amazonia. Occurs in a few protected coastal areas, including Salamanca National Park and probably also Corales del Rosario National Park (Colombia), Morrocoy National Park (Venezuela) and Wia-Wia and Galibi Nature Reserves (Suriname). Destruction of mangrove habitats in coastal portion of its range is the most important threat facing this species. It may not occur in any protected zones within its river-island distribution in Amazonia, although relatively little pressure from habitat destruction here. Extensive forest clearing, however, has occurred on larger islands in lower parts of Amazon.
Bibliography. Amorim & Piacentini (2007), Beecher (1951a), Burns *et al.* (2003), David & Gosselin (2002a), Ffrench (1991), Haverschmidt (1954b), Haverschmidt & Mees (1994), Hellmayr (1935), Hilty (2003), Hilty & Brown (1986), Lefebvre *et al.* (1992), López-Lanus (2001), Lovette & Bermingham (2002), Meyer de Schauensee & Phelps (1978), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Ridgway (1902), Schäfer & Phelps (1954), Schulenberg *et al.* (2007), Sick (1985, 1993), Sidnei de Melo (2004), Snyder (1966), Souza (2002), Tostain *et al.* (1992), Zimmer (1942a).

181. Pearly-breasted Conebill

Conirostrum margaritae

French: Conirostre marguerite **German**: Perlbrust-Spitzschnabel **Spanish**: Conirrostro Pechigrís

Taxonomy. *Ateleodacnis margaritae* Holt, 1931, north bank of Amazon at Ceo de Arary, above Parintins, Amazonas, Brazil.
Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. This species was originally placed in genus *Ateleodacnis*, and some taxonomists argue that it, along with the other lowland conebills (*C. speciosum*, *C. leucogenys* and *C. bicolor*), should be returned to that genus; as a group they are morphologically quite distinct from most highland members of present genus. Monotypic.
Distribution. NE Peru on banks of lower R Napo (sightings to 50 km or more above mouth) and banks of R Amazon (vicinity of Iquitos), E in Brazil to vicinity of R Jamunda (R Nhamundá); isolated record near junction of R Beni and R Iténez (in Brazil known as R Guaporé), Bolivia.
Descriptive notes. 11·5 cm. Closely resembles *C. bicolor*. Has crown to nape and upperparts, including upperwing-coverts and tail, dull pale bluish-grey, flight-feathers dusky, narrowly edged grey, secondaries and tertials broadly edged and tinged pale grey; facial area, throat and underparts more or less uniformly pale grey, belly and crissum pale greyish-white to whitish; iris pinkish to dull reddish-pink with sandy tinge; bill dusky; legs pinkish to pale pinkish-brown. Differs from very similar *C. bicolor* in slightly paler upperparts and lack of buff tones below. Sexes alike. Immature is entirely dull olive above, with facial area and underparts dull yellowish, sides and flanks tinged olive; almost identical to immature of *C. bicolor*, and best told by habitat and by identity of accompanying adults. Voice. Song a long-sustained (up to 15 seconds or more) series of high-pitched, squeaky chipping notes, rapid and somewhat jumbled, but distinctive once learned, and very unlike that of *C. bicolor*; often notably vocal, singing until mid-morning and at intervals throughout day from high perches in *Cecropia* trees; frequently, several individuals may be heard singing at once. Thin, weak and easily overlooked calls include high "teep" and rapid "ti-ti-ti".



Habitat. Lines of mostly middle-aged *Cecropia* trees that form distinctive successional stage of colonizing vegetation on river islands along R Amazon and its major tributaries. These *Cecropia* are typically found in zones immediately following tall cane (*Gynerium*) and preceding figs (*Ficus*), and are replaced eventually by older more diverse successional vegetation stages. Seems not to use second growth that is significantly older (more diverse) or younger (e.g. not in *Tessaria*), nor does it utilize scrubby vegetation. Sea-level to c. 150 m.
Food and Feeding. Not well known. Diet probably small arthropods. Usually seen in loosely associated pairs or small groups that work rapidly through leafy canopy layer of mostly middle-aged *Cecropia*. Gleaning actions on leaves suggest that diet consists mostly of small insects, and this species is believed to concentrate on areas where leaf damage to *Cecropia* leaves is extensive.
Breeding. No information.
Movements. Not well documented, but because species' habitat is a relatively brief successional vegetation age-stage, populations are exceptionally dynamic, with numbers building quickly at suitable sites and individuals then dispersing quickly to new river-island sites. Dispersal distances unknown but populations highly mobile.
Status and Conservation. Not globally threatened. Generally rare or local; fairly common in some places. In appropriate even-aged stands of *Cecropia* on Amazonian river islands, may be not uncommon. Although present on river islands opposite Amazonas (SE Colombia), apparently no records yet in Colombian territory. Not known to occur in any protected areas, but annual cycles of flooding in its island habitat have, to this point, largely precluded significant human settlement or habitat alteration. This species may be largely buffered from problems associated with human-caused habitat loss because it uses, under normal conditions, a short-lived successional vegetation stage and is apparently well adapted to frequent dispersals; because of relatively ephemeral nature and high turnover rates of micro-habitat that it favours, presumed to be able to move easily from one river island to another, and rapidly to colonize appropriate habitat when it appears.
Bibliography. Beecher (1951a), Ridgely & Tudor (1989, 2009), Ridgway (1902), Rosenberg (1990), Schulenberg *et al.* (2007), Sick (1985, 1993), Souza (2002), Whittaker (2004), Zimmer (1942a).

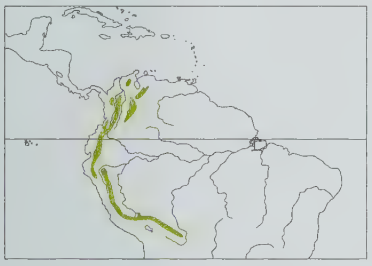
182. Cinereous Conebill

Conirostrum cinereum

French: Conirostre cendré **German**: Weißstirn-Spitzschnabel **Spanish**: Conirrostro Cinéreo
Other common names: Fraser's Conebill (*fraseri*)

Taxonomy. *Conirostrum cinereum* d'Orbigny and Lafresnaye, 1838, Yungas, Bolivia.
Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. Coastal race *littorale*, differing from others in plumage, may merit recognition as a separate species; replaced at higher elevations in Peruvian Andes by nominate, and apparently no intergrades known. N race *fraseri* differs even more from nominate, and may likewise represent a separate species. Three subspecies recognized.
Subspecies and Distribution.
C. c. fraseri P. L. Sclater, 1859 – Colombia in S part of C & E Andes (Cauca) S to S Ecuador.
C. c. littorale Berlepsch & Stolzmann, 1896 – W & NE Peru (W coast and W slope of Andes from Cajamarca, and E slope of Andes in upper Marañón Valley) S to N Chile (Tarapacá).
C. c. cinereum d'Orbigny & Lafresnaye, 1838 – C highlands and tree-line on E slope of Andes in Peru (from Huánuco) S to N Bolivia (La Paz, Cochabamba and Potosí) and N Chile.

Descriptive notes. 12–12·5 cm; 7·8–10·3 g (Chile). Greyish conebill with thin, sharply pointed bill. Nominate race has crown dusky, narrow white band on base of forehead extending rearwards as prominent white supercilium to side of rear crown, narrow dusky loral line extending through eye; side of head greyish, somewhat mixed dusky; nape and upperparts dingy grey to brownish-grey; tail dusky, tinged greyish and edged light grey; bend of wing white (usually concealed), lesser upperwing-coverts grey, median coverts dusky, edged dull pale grey, greater coverts dusky, edged grey and tipped white (forming single white wingbar); primary coverts black, flight-feathers dusky, edged pale grey, base of central primaries white (forming small L-shaped or T-shaped white patch joining single wingbar), tertials dusky, broadly edged white; below, light grey with faint brownish wash, belly and undertail-coverts greyish-buff; iris dark brown; bill black; legs dusky. Sexes similar. Juvenile has feathers of back and breast faintly tipped dusky, supercilium and underparts weakly tinged yellowish; immature similar to adult, but with buff wash on wingbars and edges of tertials. Race *fraseri* is slightly larger and darker than nominate, with crown and back greyish with brownish-olive tinge, long supercilium buff in front and fading to buff-white rearwards, underparts brownish-clay to rich buff; *littorale* is similar to nominate, but supercilium shorter, upperparts and crown tinged olive, and throat and underparts tinged buff, palest on throat. Voice. Infrequently heard song a fast jumble of twittering notes and phrases, rather like those of several congeners. In Chile song described as a fast, buzzy chatter lasting for more than a second, notes typically doubled, e.g. "ch pee'ch, pee'ch, pee'ch...". High thin "teep" call easily overlooked.
Habitat. In Andean highlands found near tree-line in dry to moderately humid zones, especially bushy woodland borders, patches of dense stunted shrubbery, gardens and other lightly wooded, drier habitats, also in *Polylepis* woodland. Race *littorale* of coastal desert and arid W slope of Andes (in Peru and NW Chile) occurs in shrubs, gardens, scrubby vegetation on slopes, and riparian vegetation along dry streambeds. At 2600–3600 m in Colombia; 2300–4000 m (mostly 2500–3500 m) in Ecuador; sea-level to 4500 m in Peru and Chile; probably mainly above c. 3000 m in Bolivia.



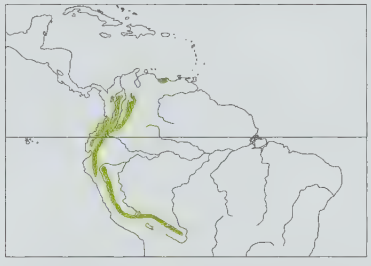
Food and Feeding. Food items appear to be mainly small insects. Seen singly, in pairs and in small parties (perhaps families); sometimes with small mixed-species flocks. Forages in active, nervous matter, gleaning from foliage of dense shrubs and stunted trees, often quite low, and sometimes clinging upside-down to inspect leaf and twig surfaces.
Breeding. Eggs in Nov in N Chile and Apr in Bolivia (La Paz); fledglings in Jun in Ecuador (Huánuco) and Aug in Bolivia (La Paz); territorial dispute and display in May and juvenile/immature, also in May, in Peru; juvenile/immature in Jul (Nariño), food-carrying adult in May and birds in breeding condition in Feb in Colombia. Nest is a woven cup made of fibres and vegetable down, and lined with horsehair; clutch 3 eggs, pale greyish-blue, thickly dotted purplish-grey. No further information available.
Movements. Mostly resident. Some local or seasonal movements likely, especially in dry tree-line zones.
Status and Conservation. Not globally threatened. Fairly common. Occurs in a number of protected areas, including Puracé National Park (Colombia), Sangay, Cajas and Podocarpus National Parks (Ecuador), Manu National Park (Peru) and Madidi and Amboró National Parks (Bolivia). Favours scrub and brushy habitat, including settled and disturbed areas, and risks to this species, whether in near term or longer term, are minimal.
Bibliography. Balderrama (2009), Burns (1997a), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Jaramillo (2003), Johnson & Goodall (1967), Koepcke (1970), Krabbe *et al.* (2001), Meyer de Schauensee (1964, 1966, 1970a), de la Peña & Rumboll (1998), Remsen *et al.* (2010), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Vogt (2006), Walker (2001), Zimmer (1942a).

183. Blue-backed Conebill

Conirostrum sitticolor

French: Conirostre à cape bleue **Spanish**: Conirrostro Dorsiazul
German: Blaurücken-Spitzschnabel
Other common names: Bolivian Conebill (*cyaneum*)

Taxonomy. *Conirostrum sitticolor* Lafresnaye, 1840, Santa Fé de Bogotá, Colombia.
Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. Four subspecies recognized.
Subspecies and Distribution.
C. s. pallidum Aveledo & Pérez, 1989 – Sierra de Perijá (Cerro Viruela), in NW Venezuela, and probably also in adjacent Colombia.
C. s. intermedium Berlepsch, 1893 – Andes in Venezuela (Trujillo, Mérida and N Táchira).
C. s. sitticolor Lafresnaye, 1840 – Andes in Venezuela (S Táchira), and from Colombia S to N Peru (Piura, Cajamarca and Amazonas).
C. s. cyaneum Taczanowski, 1875 – Andes of Peru (from Huánuco) S to Bolivia (La Paz, Cochabamba and W Santa Cruz).



Descriptive notes. 13 cm; 9·6–13·7 g (Colombia). Small, high-elevation conebill with dark head and throat, blue back and rich rufous lower underparts; rather narrow, sharply pointed and conical bill. Nominate race has entire head, neck and throat black (in S part of range, with narrow blue postocular stripe extending to nape); nape and upperparts deep blue; tail blackish, feathers narrowly edged blue (obscurely on inner feathers); lesser upperwing-coverts light blue, median coverts dusky, broadly edged blue, greater coverts blackish, edged blue; primary coverts black, flight-feathers blackish, narrowly edged blue (inconspicuous), tertials black, more broadly edged blue; chest to undertail-coverts deep ferruginous; iris dark brown; bill black; legs blackish. Sexes alike. Immature is duller grey-blue on back and throat than adult. Race *intermedium* is much like nominate, but with prominent blue stripe extending rearwards from eye to join blue of nape and upperparts; *pallidum* differs in having blue postocular stripe faint and underparts rufous (paler than other races); *cyaneum* has blue eyestripe longer, extending anteriorly to above eye, and throat and chest dark blue. Voice. Song, mostly at dawn, fast and energetic, a high-pitched, highly complex, bubbly jumble of chipping and twittering notes rather like that of some congeners and some *Diglossa*, e.g. rapid "chipapita-chipapita, jeet, chipapita...", repetitious and somewhat musical, lasting for up to 6 seconds, and sometimes given over and over again with only brief pauses. Call include an insignificant high "tsi" and "sew".
Habitat. Humid montane forest, forest borders, and stunted elfin woodland up to tree-line. At 2550–3500 m (sightings to 2300 m) in Venezuela, 2600–3700 m in Colombia, mostly 2500–3500 m (once to 3800 m) in Ecuador, and at similar elevations in Peru and Bolivia; most numerous near tree-line or slightly below.
Food and Feeding. Mainly insectivorous. Occurs in active pairs and in small groups, most often with mixed-species flocks containing other tanagers, small tyrant-flycatchers (Tyrannidae) and New World warblers (Parulidae). A quintessential "gleaner" of minute items from axils of stiff, dense whorls of leaves and on twig and other leaf surfaces, which it finds by peering downwards or stretching upwards to overhead surfaces. Hops in dense foliage, also hangs upside-down to probe moss, and occasionally executes short sallies to air. Frequently forages and sings from fairly exposed sites, and not particularly difficult to see.
Breeding. In Colombia, fledglings in Nov and Jan (Cundinamarca and Cauca), juveniles/immatures in Feb, Jul, Sept and Oct (Andes) and two breeding-condition birds in Feb and Jul, respectively (C Andes); fledglings and juveniles in Jul and Aug in Ecuador, in Apr, Jun, Oct and Nov in Peru, and in Sept and Oct in Bolivia. No other information.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Uncommon to fairly common. Can be found in numerous protected areas, among them Sierra Nevada and Tamá National Parks (Venezuela), Chingaza, Puracé, Los Nevados (Tolima) and Nevado de Huila National Parks (Colombia), Cajas, Sangay and Podocarpus National Parks (Ecuador), Tingo Maria and Manu Parks (Peru), and Madidi National Park (Bolivia). This species' range also includes a considerable extent of suitable habitat that is not protected, but is at relatively low risk in the short term. Most serious long-term risk is deforestation.
Bibliography. Álvarez-Rebolledo & Córdoba-Córdoba (2002), Anon. (2000), Aveledo Hostos & Pérez Chinchilla (1989), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Johnson & Goodall (1967), Krabbe *et al.* (2001), Lovette & Bermingham (2002), Meyer de Schauensee (1966, 1970a), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Zimmer (1942a).

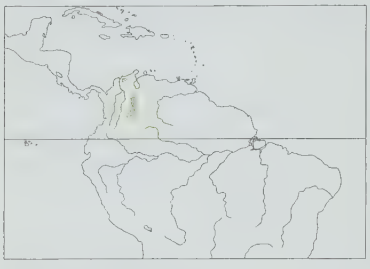
184. Capped Conebill

Conirostrum albifrons

French: Conirostre coiffé **German**: Kappenspitzschnabel **Spanish**: Conirrostro Coronado
Other common names: Blue-capped Conebill ("*atrocyaneum* group"); White-capped Conebill (*cyanonotum*, *albifrons* and *centralandium*)

Taxonomy. *Conirostrum albifrons* Lafresnaye, 1842, Bogotá, Colombia.
Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. Dark-crowned races *atrocyaneum*, *sordidum* and *lugens* have sometimes been regarded as representing a separate species. Six subspecies recognized.
Subspecies and Distribution.
C. a. cyanonotum Todd, 1932 – N Venezuela (coastal cordillera of Aragua, Vargas and Distrito Federal).
C. a. albifrons Lafresnaye, 1842 – W Venezuela (Andes of S Táchira) and W slope of E Andes of Colombia (S to latitude of Bogotá).
C. a. centralandium Meyer de Schauensee, 1946 – C Andes of Colombia (Antioquia S to W Huila, and on E slope in Nariño).
C. a. atrocyaneum Lafresnaye, 1848 – W Andes of Colombia (Antioquia S on W slope to Nariño) S through Ecuador to N Peru (Piura and Cajamarca).
C. a. sordidum Berlepsch, 1901 – Andes of C Peru (from Junín) S to N Bolivia (La Paz).
C. a. lugens Berlepsch, 1901 – Andes of Bolivia (Cochabamba and Santa Cruz).

Descriptive notes. 13–13·5 cm; 11·7–21·5 g (Colombia). Medium-sized conebill with thin, sharp bill and tail-wagging habit. Male nominate race has crown snowy white; rest of plumage mostly dull black, becoming ultramarine-blue on scapulars and lower mantle, down onto uppertail-coverts (bluish tinge most obvious in hand); tail dusky, tinged dark blue, lesser upperwing-coverts glossed dark blue to violaceous, median coverts dull black, edged dark blue, rest of wing dull black, faintly edged dark blue; iris dark brown; bill dark grey, paler base; legs dark grey. Female has crown dull blue, becoming blue-tinged greyish on nape and side of head; upperparts olive-green, lesser wing-coverts pale green, greater coverts, flight-feathers and tail dusky, edged olive-green; throat, chest and median breast pale grey with hint of bluish tinge, sides, flanks and lower underparts contrastingly yellowish-olive. Immature is much like female; subadult male (in transitional plumage) resembles female, but shows blue on shoulders and bluish-black on back. Races differ mainly in crown colour of male: *centralandium* is much like nominate, but crown often flecked with blue, underparts tinged bluish, and rump brighter; *cyanonotum* has crown deep violet-blue with faint silvery streaking, often the pale streaks mixed with a few dark blue feathers; *atrocyaneum* has crown deep purplish-blue; *sordidum* has crown brighter blue than previous, outer margins of primaries faintly greenish (instead of bluish), and plumage overall with less ultramarine gloss, female crown darker blue than previous; *lugens* is very similar to last, but plumage with more ultramarine gloss. Voice. Infrequently heard song, mainly at dawn, a high-pitched and penetrating "itsu-tseeu, tsu-tseeu, tsu-tseeu", usually preceded by jumbled "tsududuit"; in Peru, described as variable, but usually high-pitched and wiry, repetitive series of notes, sometimes with different ending, "ti-teeteetee tzeew-tzeew"; in Cuzco (SE Peru), song at dawn a short, high and weak "tzeet! tee-tee-tzeeeeu", with high thin "teet" note irregularly between songs. Calls a rich "tchew" and high "sick".
Habitat. High humid and wet montane forest, especially at forest borders; also older disturbed vegetation, alders (*Alnus*) in landslides, and taller second growth. Recorded at 1500–3000 m, most records at or above c. 2000 m; in coastal cordillera of N Venezuela, race *cyanonotum* occurs mainly from 1850 m to 2000 m (maximum elevation of much of the cordillera); common down to c. 2000 m in Urubamba Valley, in S Peru.
Food and Feeding. Diet mainly (possibly entirely) insects. Forages singly or, more often, in pairs or small groups, and as a rule is seen with mixed-species flocks containing small tyrant-flycatchers (Tyrannidae), *Diglossa* flowerpiercers and other tanagers. Food items gleaned or picked from leaves, leaf axils and bud tips in high outer foliage; rarely seen lower down. Moves actively, usually working outwards along branches with peculiar, slightly crouching and twisting gait, this accentuated by habit of continually flicking up tail. Also occasionally hangs upside-down or with head downwards to inspect surfaces briefly.
Breeding. Birds in breeding condition in Mar–Sept in Andes of Colombia. No further information available.
Movements. Resident.
Status and Conservation. Not globally threatened. Generally fairly common over much of range. Occurs in numerous protected areas, among them El Avila, Henri Pittier, Guaramacal, Sierra Nevada and Tamá National Parks (Venezuela), Chingaza, Cueva de los Guacharos, Puracé, Las Orquídeas and Farallones de Cali National Parks and Reinita Cielo Azul, Tambito and Río Blanco de Manizales Nature Reserves (Colombia), Sangay and Podocarpus National Parks (Ecuador), Manu National Park (Peru), and Madidi National Park (Bolivia). This species utilizes both primary forest and a variety of older-stage second-growth woodland types, including alders in landslides; it is not at risk in the foreseeable future. In the longer term, deforestation and forest fragmentation may pose a risk.
Bibliography. Donegan & Dávalos (1999), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), Krabbe *et al.* (2001), Meyer de Schauensee (1964, 1966, 1970a), Meyer de Schauensee & Phelps (1978), Moore *et al.* (1999), Remsen *et al.* (2010), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg *et al.* (2007), Walker (2001), Yuri & Mindell (2002), Zimmer (1942a).



185. Rufous-browed Conebill

Conirostrum rufum

French: Conirostre roux **German**: Rotbrauen-Spitzschnabel **Spanish**: Conirrostro Rufo

Taxonomy. *Conirostrum rufum* Lafresnaye, 1843, Santa Fé de Bogotá, Colombia.
Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. Monotypic.

Distribution. E Andes from W Venezuela (extreme S Táchira) S locally in adjacent Colombia from Norte de Santander (Páramo de Guerrero, W of Salazar) to latitude of Bogotá; also Santa Marta Mts (N Colombia).

Descriptive notes. 13 cm; mean 11 g. Small, dark *Conirostrum* with deep rufous face and underparts, and short, thin, sharply pointed bill. Has crown to uppertail-coverts plumbeous grey, often with brownish tinge on crown to mantle, not sharply defined from the ochre-cinnamon to chestnut-rufous on forehead, eyebrow, side of head and neck, and entire underparts, this colour being richest on forehead and eyebrow and duller on side of head, especially in duskier lores and postocular stripe; tail dusky; upperwing-coverts, flight-feathers and tertials dusky, base of outer flight-feathers sometimes with small narrow whitish spot (often obscure or absent) formed by white on outer web of a few outer primaries; tertials narrowly edged dull white to buffy white; iris dark brown; bill blackish; legs dark grey. Sexes similar. Juvenile is like adult, but duller, with underparts pale cinnamon to buff-coloured. Voice. Song, mainly at dawn, a very fast short, squeaky phrase, "ta-twée-ta-twéet", about one phrase per second, repeated up to 15 times or more without interruption in fast, complex stream of notes, often with additional notes squeezed in between each phrase; accented notes in each phrase form unmusical rhythmic pattern or "beat"; songs also may be more complex, but typically include repetitive, accented notes or phrases repeated over and over that lend a rhythm to the song, e.g. "ta'ta'te'pfitsa'pfitsa'pfitsa'ta'ta'ti' pfitsa' ta'tati-e..." and so on, in rapid stream lasting up to 6 seconds or more.

Habitat. Bushy and shrubby vegetation in fairly dry to humid areas, including borders of humid and wet stunted forest and elfin woodland up to tree-line; shrubs and woody regrowth vegetation dominated by Andean oak (*Quercus humboldtii*) on drier hillsides, and in a mix of native and exotic trees in parks, gardens and urban areas (e.g. around Bogotá), and in shrubs and trees around small wetlands (*humedales*) on Sabana de Bogotá, and occasionally foraging out into tall reeds and sedges in marshes. Not found inside forest. Recorded at c. 2600–3300 m (tree-line) in Colombian Andes and Santa Marta Mts; in Venezuela, reported only at 2800 m (four specimens) in S Táchira (Cerro Retiro).

Food and Feeding. Mainly small insects. Encountered mostly singly or in pairs, less often in small groups which likely represent families; may follow mixed-species flocks containing small tyrant-flycatchers (Tyrannidae), *Diglossa* flowerpiercers and other tanagers, although more often seen foraging independently of them. Forages mostly in tops of shrubs, shorter vegetation and smaller trees or somewhat higher, but infrequently in tops of tall trees. Mainly probes and gleans from dense tufts of leaves, in leaf axils, dense flowerheads (e.g. Asteraceae), and gleans from twig surfaces, much in manner of *C. sitticolor*.

Breeding. In Colombia, fledglings found in Jul, Aug and Dec in Cundinamarca and Oct in Santander, and six birds in breeding condition in Feb–Sept in Santa Marta Mts and E Andes. Nest a small cup constructed from dry grasses and other plant material; one nest was located 2·5 m up in blackberry thicket (*Rubus*) at edge of road and was camouflaged with dry blackberry leaves incorporated into exterior. Clutch 2 eggs. No other information.

Movements. Resident. No migratory movements reported, although local seasonal movements possible; in marsh edges and semi-open areas at Parque La Florida, in Bogotá, more numerous during Jan–Apr than during May–Jul.

Status and Conservation. Not globally threatened. Restricted-range species: present in Colombian East Andes EBA and Santa Marta Mountains EBA. Locally fairly common to common. Reported as "rare" in Santa Marta Mts, but this may be an artefact of the difficulty of sampling appropriate habitat in this region. Few records from Venezuela. In Colombia, occurs in shrubby and cut-over areas, and is at least seasonally common in shrubby areas in Parque La Florida, in Bogotá, and shrubbery and trees around other wetlands; occurs also in Chingaza National Park (Cundinamarca), and in scrubby and cut-over vegetation in drier oak-dominated regions in N Boyacá (e.g. near Soatá); almost certainly occurs also in Tamá National Park. Despite small range, appears not to be threatened because of its ability to utilize bushy second growth.

Bibliography. Anon. (2000), Athanas (2010b), Carriker (1941–1954), Fjeldså & Krabbe (1990), Hilty (2003), Hilty & Brown (1986), López-Lanus (2007), Restall *et al.* (2006), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Todd & Carriker (1922).

186. Tamarugo Conebill

Conirostrum tamarugense

French: Conirostre des tamarugos **Spanish**: Conirrostro de Tamarugal
German: Rotstirn-Spitzschnabel

Taxonomy. *Conirostrum tamarugense* Johnson and Millie, 1972, in the northern area of the recently developed Tamarugo plantations which extend on either side of the Panamerican Highway in Lat. 20°30', Tarapacá, Chile.

Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. Monotypic.

Distribution. SW Peru (arid highlands in Arequipa, Moquequa and Tacna) and N Chile (S, patchily, to Tarapacá).

Descriptive notes. 12·5 cm; two females from Chile each 10·5 g. Small greyish-and-rufous conebill with thin, sharply pointed bill. Male is dark grey above, with short bright rufous supercilium, grey lores, and rufous throat and chest (may not contrast strongly with grey of rest of plumage); tail dusky; bend of wing and lesser upperwing-coverts grey, median and greater coverts dusky, edged grey and tipped pale cinnamon (forming two narrow wingbars, often weakly indicated), flight-feathers dusky, edged pale grey and with small but prominent white patch at base of primaries (wingband most visible in flight); side of head, and underparts below rufous of throat and chest plain grey, becoming buffy white on centre of belly; undertail-coverts contrastingly rufous; iris dark brown; bill black; legs dark grey. Female is similar to male, but duller and browner. Immature is even duller and paler, with supercilium faint or lacking, wingbars narrower and paler (buff), and patch on throat and chest buff to chamois, or faintly indicated as a rusty wash, or almost entirely lacking, belly and undertail-coverts buff. Voice. Song resembles that of *C. cinereum*, a fast, buzzy jumble of squeaks lasting c. 1 second, with slightly higher-pitched single-syllable notes interspersed; in Chile described as a fast, buzzy chatter lasting less than 1 second, "chit-chit-chit-chit", resembling song of *C. cinereum* but notes single (not doubled) and higher-pitched. Call a high-pitched "tsee".

Habitat. Patches of sparse, low, scrubby woodland, especially *Polylepis* trees, also in *Gynoxys*, in dry and arid zones; in N Chile found mostly in mature tamarugo (*Prosopis tamarugo*) plantations, and to lesser extent in riverine scrub, agricultural land and citrus groves. Mainly at 3400–4100 m, rarely as low as 1300 m in Tacna (Calientes), in Peru; sea-level to c. 2950 m in Chile.

Food and Feeding. Poorly known. Diet includes caterpillars, especially those of lycaenid butterfly *Leptotes trigemmatus*. Forages in pairs and small groups; often in small mixed-species flocks with *C. cinereum* in Chile, and loosely associated with various furnariids in Peru. Gleans items from foliage.

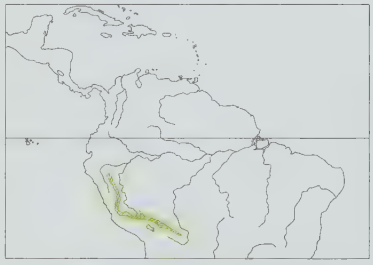
Breeding. Season at least Sept–Dec, coinciding with seasonal blooming of tamarugo flowers (which provide food for *Leptotes trigemmatus* caterpillars); immature-plumaged birds in Jul in Peru (Arequipa) and Dec in Chile (Tarapacá). Breeds in tamarugo woodland in Chile. No other information.

Movements. Migratory. Following breeding (in Chile), migrates N to SW Peru, where apparently reported between about Apr and Nov. In Chile, makes post-breeding movement to higher elevations and into pre-*puna* shrub zones.

Status and Conservation. VULNERABLE. Restricted-range species: present in Peru-Chile Pacific slope EBA. Locally common breeder in Chile; locally fairly common non-breeding visitor in Peru, where seen with some regularity above Chiguata, on Arequipa–Puno Road. In 1993, estimated global population little more than 35,000 individuals, within breeding range of 108 km²; possibly increasing with expansion of suitable habitat. In Chile, largely restricted to two populations within Pampa del Tamarugal National Reserve, in Tarapacá; occurs, and probably breeds, also in tamarugo forest S of Arica in R Chaca (Vitor) valley, and possibly present farther upriver from there. May perhaps breed near Zapiga and in other large forested areas in Pampa del Tamarugal S of known range. Potential changes in forest management could severely affect entire population.

Bibliography. Anon. (2010a), Athanas (2010b), Butchart & Stattersfield (2004), Estades (1996), Estades & Lopez-Calleja (1995), Jaramillo (2003), Johnson & Goodall (1967), López-Calleja & Estades (1996), Mayr & Vuilleumier (1983), de la Peña & Rumboll (1998), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Schulenberg (1987), Schulenberg *et al.* (2007), Silva-Aranguiz (2010), Stattersfield & Capper (2000).

187. White-browed Conebill



Conirostrum ferrugineiventre

French: Conirostre à ventre roux **Spanish**: Conirrostro Cejiblanco
German: Weißbrauen-Spitzschnabel

Taxonomy. *Conirostrum ferrugineiventre* P. L. Sclater, 1855, Bolivia.

Genus has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Oreomanes* as sister-group. Has hybridized with *Oreomanes fraseri*. Monotypic.

Distribution. Highlands and tree-line on E slope of Andes in C & S Peru (S San Martín, Huánuco, Junín and Cuzco, probably also Puno) and tree-line on E slope of Bolivian Andes (in La Paz, Cochabamba and W Santa Cruz).

Descriptive notes. 12 cm; 11–12 g. Small grey-and-rufous conebill with prominent white eyebrow, and thin, sharply pointed bill. Has crown blackish, bordered by long white supercilium from base of upper mandible back to nape; lores and subocular area black (forming short, triangular mask), sometimes with a few thin whitish streaks; rear ear-coverts and side of neck blue-grey; entire upperparts and tail blue-grey; birds from N part of range (Huánuco, in Peru) have slightly darker crown, bluer back and buff-tinged supercilium; upperwing-coverts dusky-grey, edged slightly paler grey (edging not conspicuous), primary coverts black, flight-feathers and tertials dusky with blue-grey edgings (edges of primaries sometimes whitish); white throat and submoustachial line separated by narrow dark greyish malar stripe; underparts, including belly and undertail-coverts, rufous; iris dark brown; bill dusky; legs dusky grey. Sexes similar. Juvenile is similar to adult, but moustache and upperparts greyer, supercilium buffy white, pale shaft streaks on side of head, tertials distinctly edged whitish, and may show dusky speckling on back and breast; immature like juvenile, but lacks speckles on back and underparts. Voice. Infrequently heard song, mainly at dawn (in Peru), typically from exposed branch at top of shrub or tree, a jumble of high, thin, and wiry notes. Call a high, thin "tsit".

Habitat. Borders of humid and wet stunted forest (to c. 10 m), including *Polylepis*, and in shrubs and bushes on humid slopes up to tree-line; also shrubbery in lower zones of *páramo*, and occasionally in semi-humid *Polylepis* woodland. At 2500–4100 m in Peru; mostly 3000–3600 m and in vicinity of tree-line.

Food and Feeding. Small arthropods. Forages alone, in pairs, and sometimes with small mixed-species flocks containing New World warblers (Parulidae), *Diglossa* flowerpiercers and other tanagers; reported also as associating with *Oreomanes fraseri*. Observed mainly when gleaning for insects in leaves and on twigs in middle and upper parts of shrubs and small trees. Tends to forage within canopy crown, keeping mostly hidden from view, and often hangs downwards in thin outer foliage.

Breeding. No information.

Movements. Primarily resident. Periodic downslope movements may occur during periods of inclement weather.

Status and Conservation. Not globally threatened. Fairly common. Occurs in Manu National Park and possibly a few other high-elevation protected areas in Peru and Bolivia. Firewood-cutting, deforestation for human settlement, and disturbance of tree-line habitats may eventually exert an adverse impact on this species' overall distribution and abundance.

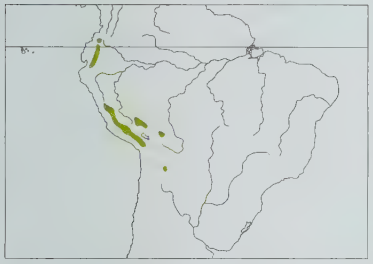
Bibliography. Clements & Shany (2001), Fjeldså & Krabbe (1990), McCarthy (2006), Mayer (2000), Ridgely & Tudor (1989, 2009), Schulenberg (1985), Schulenberg *et al.* (2007), Walker (2001), Zimmer (1942a).

PLATE 21 ➤

PLATE 21

inches 2
cm 5

Genus *OREOMANES*



P. L. Sclater, 1860

188. **Giant Conebill**

Oreomanes fraseri

French: Conirostre géant **German**: Riesenspitzschnabel **Spanish**: Conirrostro Gigante

Taxonomy. *Oreomanes fraseri* P. L. Sclater, 1860, Panza, 14,000 feet [c. 4265 m], Chimborazo, Ecuador.
Has sometimes been placed in Coerebidae or Parulidae, but molecular-genetic data indicate that it belongs in present family, with *Conirostrum* as its sister. Genus sometimes subsumed in latter; hybrid between this species and *Conirostrum ferrugineiventre* also suggests close relationship. Geographical variation minor, partly clinal, and with checkerboard pattern, in general bill length increasing from N to S, plumage becoming paler from N to S, and differences in facial plumage varying independently of geographical location (and often much variation within a single population); proposed races *binghami* (described from Cedrobamba Ruins, near Machu Picchu, at timber-line in SE Peru) and *sturninus* (from Finca Salo, at c. 3960 m in Potosí, in Bolivia) considered undiagnosable. Monotypic.
Distribution. Extreme S Colombia (volcanoes on border) S in high Andes to Ecuador (S to Azuay and N Loja), and NC Peru S to extreme N Chile (Tarapacá), Bolivia and NW Argentina.

Descriptive notes. 16·5 cm; 22–27 g. Large grey-and-rufous conebill having rather long straight, sharply pointed, conical bill. Has crown and upperparts grey, short rufous to dark chestnut supercilium; forehead and sometimes narrow supraloral line white, or forehead streaked/mottled with white; cheek and lower ear-coverts white (amount of white variable, in some areas extending over much of lower side of head); lores and chin black or mottled with black; lesser upperwing-coverts grey, rest of wing-coverts and flight-feathers dusky, edged grey, tertials dusky with narrow grey edges; throat and underparts entirely chestnut except for grey thighs; iris dark reddish-brown; bill dusky; legs dark grey. Sexes alike. Juvenile is tinged brownish above, has extensive brownish and dusky mottling on head and underparts; immature similar to adult, but paler below, and with white throat and much more extensive white on face, also may show dusky markings on throat (especially at side). Voice. Notably quiet, although occasionally gives weak, high "chip" note. Infrequently heard song, in Ecuador, a fairly musical twittering, e.g. "cheet, cheeveét, cheeveét". In Peru presumed dawn song a repetitive 2-note series interspersed with higher notes, "tew-tuséétu tew-tuséétu tsee tew tew-tuséétu..."; possible day song a high, squeaky and jerky warble.
Habitat. Found almost entirely in dry to humid, moss-covered *Polylepis* shrub, and taller canopied *Polylepis* woodland; sometimes visits *Puya* and *Gynoxys* adjacent to *Polylepis*, but otherwise not found outside pure or mixed stands of *Polylepis*. Recorded at elevations of 2700–4850 m, mainly at 3300–4500 m.
Food and Feeding. Diet poorly known; takes small arthropods, including beetles (Coleoptera), small larvae and spiders (Araneae). Single birds, pairs or families sometimes loosely associated with other species. Typically, forages in slow, quiet and inconspicuous manner, this aided by grey and rufous colours of plumage, which closely match the cinnamon colour of *Polylepis* bark and the interplay of light and shadows on interior branches. Searches mainly on trunks and medium-sized to large limbs in interior of *Polylepis* trees, where it probes beneath the thin peeling bark; may open bill under bark to separate the scaly layers; may remain for several minutes within a small tree, carefully working along and around trunk and limbs somewhat in manner of nuthatch (*Sitta*). Does not descend head first, but may cling upside-down or clamber along with legs widely spread. Reported also as gleaning aphids (Aphidoidea) and sugar secretions from beneath *Gynoxys* leaves, and may probe flowers of mistletoes (Loranthaceae) and *Puya*. After a foraging bout, apt to fly off some distance, sometimes even to a distant grove of *Polylepis*.
Breeding. Season mainly Sept–Dec, at beginning of rainy season, near Cochabamba, in Bolivia, where eight nests found; fledglings in Aug (Lima), Nov (Puno) and Dec (Cuzco) in Peru. In Bolivia, nest an open cup constructed mostly from material from *Polylepis* trees and mosses, averaged external width 20 cm, with thick rim 5·5 cm, located in tree (average 3·16 m in height), well camouflaged, in interior of *Polylepis* forest; mean clutch size 1·86 eggs. No further information available.
Movements. Apparently resident.
Status and Conservation. Not globally threatened. Currently considered Near-threatened. Rare to uncommon, very local and declining. Occurs in a few protected areas, among them Cajas National Park (Ecuador). Restricted to *Polylepis* woodland, a habitat which has been destroyed or extensively degraded by firewood-gathering and burning throughout much of Andes. This habitat is now highly fragmented, and the number of *Polylepis* woodland sites large enough to support this species are declining steadily. Some estimates suggest that as little as 10% of *Polylepis* woodland remains intact, and much of what survives may be too small or too heavily damaged to be utilized by present species. Human disturbance, especially burning and wood-cutting, are greatest ongoing threats.
Bibliography. Anon. Genus *XENODACNIS*

Cabanis, 1873

189. **Tit-like Dacnis**

Xenodacnis parina

French: Xénodacnis mésange **German**: Meisenpitpit **Spanish**: Dacnis Andino

Taxonomy. *Xenodacnis parina* Cabanis, 1873, Maraynioc, Peru.
Has sometimes been placed in family Coerebidae; recent molecular-genetic data, however, indicate that it belongs in present family and is closest to genus *Diglossa*, and also to *Haplospiza*, *Acanthidops* and *Catamenia*, the last three genera currently placed in Emberizidae. Races *petersi* and *bella* have been considered to represent a separate species, distinct from smaller S nominate race, although plumage differences from latter not very pronounced. Race *bella* closely resembles *petersi* and should perhaps be synonymized with it. Three subspecies currently recognized.
Subspecies and Distribution.
X. p. bella J. Bond & Meyer de Schauensee, 1939 – NC Peru (S Amazonas and La Libertad N of R Marañón).
X. p. petersi J. Bond & Meyer de Schauensee, 1939 – C Peru on W slope of Andes in Ancash, Huánuco (W of R Marañón) and Lima.
X. p. parina Cabanis, 1873 – S Peru on E slope of Andes in Junín, Ayacucho, Apurímac, and Cuzco, and the W slope in Arequipa.
Also, race uncertain, SC Ecuador (NW Azuay and NW Morona-Santiago); sightings and specimens believed probably referable to *bella*.

Descriptive notes. 11 cm, male 11–12 g, female 10–12 g (nominate); 13 cm, male 15·4–18·5 g, female 11·5–17·5 g (other races). Small, with short, thin bill. Male nominate race is essentially all dark blue with faint greyish tinge above and below, sometimes with indistinct thin silvery streaking on crown, back, rump and throat and central breast; lesser and median upperwing-coverts dark blue, greater coverts dusky, broadly edged and tinged medium blue, flight-feathers and tertials and tail dusky, edged medium blue; iris dark brown; bill blackish; legs dark grey. Female has crown and central nape blue, upperparts light brownish-olive, lower back more greyish with hint of blue wash, lesser upperwing-coverts blue, rest of coverts and flight-feathers dusky with little evident blue tinge; throat and underparts deep cinnamon-buff, fading to buff on belly. Immature and subadult are dingy greyish-brown with obscure blue tinge on wings, and slightly paler below. Races differ markedly in size (nominate notably smaller than others), rather less in plumage: *bella* male is very like nominate, all dark blue but lacking greyish tinge, and regularly with thin silvery streaking throughout, female with blue forehead, lores and ocular area (forming small blue mask across eye), otherwise greyish-brown above and with lesser and median wing-coverts medium blue, primary coverts dark blue, rest of wing feathers and tail dusky with inconspicuous brownish edges (or tail with tinge of blue), throat and breast cinnamon, becoming buff to whitish on belly (paler below than nominate); *petersi* male differs little from previous, although marginally larger and perhaps with slightly brighter streaking. Voice. Notably vocal, some calls, and especially the song, being surprisingly loud. Song, in Peru, a fast variable series of whistles, "zwit-zwit-zwit-zwit-zhweet-zhweet-zhweet..." and so on, the first series lower, the last higher; number of notes in series variable, sometimes only a series of "zwit" notes given, and sometimes female joins male in antiphonal duet in which she gives harsher or scratchy notes that continue after male finishes.
Habitat. At or above tree-line in stunted woodland, often in *Polylepis* groves where mixed with *Gynoxys* shrubs. *Gynoxys* may be a critical plant within territories; where *Gynoxys* is abundant, populations of this tanager are often very numerous. At c. 3700–4000 m in Ecuador; 3200–4600 m in Peru.
Food and Feeding. Tiny arthropods, including aphids (Aphidoidea) and sweet nectar-like secretions, both liquid or crystalline, deposited on leaves by aphids (or excreted by leaves themselves), also takes other, aphid-like insects; has been seen feeding at flowers and with nectar observed on feathers. Fourteen stomachs contained only insects, including caterpillars. Occurs in pairs and in small chattery groups, sometimes in remarkably high densities of a dozen or more per hectare in Peru, individuals aggressively attempting to defend tiny territories. Moves quickly from shrub to shrub, where it gleans tiny insects from undersides of leaves. Also forages often on *Gynoxys* shrubs.
Breeding. Juveniles observed in various stages of moult in Feb in Ancash, and fledglings seen in May in Ancash and in Jul on Ancash–Huánuco–Lima border; likely that more than one brood attempted per season when food abundant. Nest a tiny cup made form "wool" of *Gynoxys* shrub, located in tree (no height given, but presumed fairly low). No other information.
Movements. Resident. Concentrates locally in high numbers, but no long-distance or significant elevational movements reported.
Status and Conservation. Not globally threatened. Fairly common very locally in both Ecuador and Peru. Only known populations in Ecuador occur in or near El Cajas National Park and Sangay National Park; while sites within the parks are protected, others are not, and population of this species in Ecuador must be small. More widespread in Peru and may occur in a few protected areas, but its tree-line habitat, especially *Polylepis*, is now fragmented and under constant pressure from firewood-cutting, land clearance and fires associated with human activities. Given the small population and pressure on its habitat, this species may soon be listed as Near-threatened or perhaps even Vulnerable.

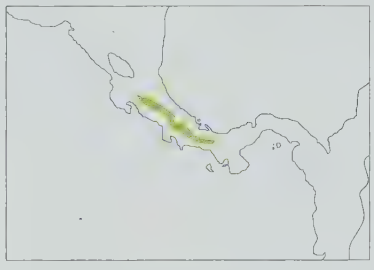
Genus *DIGLOSSA* Wagler, 1832

190. Cinnamon-bellied Flowerpiercer

Diglossa baritula

French: Percefleur cannelle **Spanish**: Pinchaflor Ventricanelo
German: Zimtbauch-Hakenschnabel
Other common names: Highland/Cinnamon Flowerpiercer, Highland Honeycreeper

Taxonomy. *Diglossa baritula* Wagler, 1832, Mexico.
Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. This species forms a superspecies, and formerly considered conspecific, with *D. plumbea* and *D. sittoides*, genetic data suggesting that the three form a monophyletic group. Three subspecies recognized.
Subspecies and Distribution.
D. b. baritula Wagler, 1832 – C Mexican highlands from Jalisco, Guanajuato, Hidalgo and Veracruz S to Isthmus of Tehuantepec in Oaxaca; also coastal chain in Guerrero and Oaxaca.
D. b. montana Dearborn, 1907 – highlands of S Mexico (Chiapas), Guatemala and El Salvador.
D. b. parva Griscom, 1932 – highlands of W & C Honduras and CN Nicaragua.



Descriptive notes. 11 cm; 6–15 g. Small flowerpiercer with slender and slightly recurved bill, lower mandible more obviously upturned than upper mandible, upper mandible with sharp hook at tip. Male nominate race has head and upperparts dusky blue-grey to dark plumbeous grey, more blackish on head; upperwing-coverts and flight-feathers narrowly edged dull blue; throat and entire underparts dull rufous; iris dark brown; bill blackish on tip and upper mandible, most of lower mandible pale grey to pinkish-horn; legs pinkish-grey. Female is dull greyish-olive above, including head; wings and tail darker, usually with narrow paler edging on wing-coverts, flight-feathers and, more broadly, tertials; throat and underparts greyish-olive, paler than above and tinged cinnamon, throat and breast faintly streaked with buff, belly cinnamon. Juvenile is much like female, but usually slightly darker, more brownish, above, and with single pale buff lower wingbar, flight-feathers edged olive, throat and chest light olive-grey with distinct yellowish tinge and blurry streaking, lower underparts light cinnamon; subadult male much like adult female, but with variable amount of olive on upperparts and throat, and breast and lower underparts often tinged with cinnamon. Race *parva* male differs from nominate in having throat dusky grey, underparts dull rufous; *montana* is similar to previous, but grey of throat extends somewhat onto chest, and birds from highlands S of Isthmus of Tehuantepec have undertail-coverts slightly tinged cinnamon. VOICE. Call, in Mexico, a high, thin, sharp "tsi" or "tsik" and a quite mellow trill, "truuuur". Song a high, thin slightly squeaky twittering warble, increasing in intensity and then fading, "ss-ssi-ssi-ssiiu-i-siin-i-siin-i", with variations.
Habitat. Favours bushy areas with flowering shrubs in overgrown clearings, pastures, gardens and borders of pine–oak (*Pinus–Quercus*), fir (*Abies*) and broadleaf evergreen forest in fairly dry to humid zones; often in flower gardens in settled areas. Mostly 1200–3350 m (tree-line) in Mexico and elsewhere; may wander lower seasonally.
Food and Feeding. Nectar, as well as some insects. Found singly, in pairs and in family units, infrequently as many as 10 individuals together. Like congeners, a hyperactive species that moves quickly, flitting from one flower blossom to the next, often remaining in relatively small area and tending to keep out of sight. Examines flowers at almost any height, from near ground to tops of foliage; pauses for scarcely a second at each flower, where it clings to flower stalks and uses lower mandible to puncture bases of corollas in order to reach nectar within. Also makes short aerial sallies of a few metres to chase down flying insects.
Breeding. Unusual biannual breeding cycle reported during four-year study in Mexico: breeding Jan–Apr dry season and Jul–Oct rainy season (latter coinciding with that of resident Trochilidae), but cycles skewed, c. 90% of females of present species breeding in rainy season and only 30% in dry season, whereas proportion of males in breeding condition about the same in each period (86% and 92%, respectively); also, some males underwent two complete moults annually (unlike females), though moulting of both sexes heavily concentrated during rainy season (when apparently more food resources available). Two nests described, each a deep open cup built from dead leaves, pine needles and fine rootlets, one 1·2 m above ground between two cypress saplings, the other 1·5 m up in shrub in bushy pasture. One nest held 2 eggs, bright blue, heavily spotted brown on large end; incubation by female alone; chicks fed by both adults, male reportedly feeding more than did female, apparently mostly with regurgitated insects. No other information.
Movements. Moves up and down mountain slopes seasonally to take advantage of seasonal flowering and shifting nectar abundance.
Status and Conservation. Not globally threatened. Fairly common to common. Because of its ability to utilize nectar sources in gardens and cultivated areas, this species faces no immediate threats.

191. Slaty Flowerpiercer

Diglossa plumbea

French: Percefleur ardoisé **German**: Einfarb-Hakenschnabel **Spanish**: Pinchaflor Plomizo
Other common names: Slaty Flowerpecker

Taxonomy. *Diglossa plumbea* Cabanis, 1861, Costa Rica.
Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Forms a superspecies, and formerly considered conspecific, with *D. baritula* and *D. sittoides*, genetic data suggesting that the three form a monophyletic group. Proposed race *veraguensis* (described from Cordillera de Veraguas, in SW Panama) is now considered to be inseparable from populations in rest of species' range. Monotypic.
Distribution. Highlands of Costa Rica (from C Guanacaste) S to W Panama (E to Veraguas).

Descriptive notes. 11 cm; 9·3–10·1 g. Small, plain grey or brown flowerpiercer with slender and slightly recurved bill, lower mandible more obviously upturned than upper mandible, upper mandible with sharp hook at tip. Male has crown and upperparts blackish-grey with faint bluish tinge, tail blackish-grey, lesser and median upperwing-coverts dusky grey, greater coverts and flight-feathers blackish with slightly paler edgings; throat and underparts dark slate-grey, slightly paler than upperparts, and palest on centre of belly; iris dark brown; bill black above, mostly pale flesh-grey below, with darker tip; legs pinkish-grey. Female is plain greyish-olive above, wing-coverts and flight-feathers darker and narrowly edged olive; throat and underparts light greyish-olive, paler than upperparts and with hint of buff streaking on throat and breast, belly whitish, undertail-coverts tinged cinnamon; much like female of *D. baritula*. Subadult male is very like female or slightly darker. VOICE. Both calls and song weak and not far-carrying. Call a high, thin, weak "tsip" or a piercing "tsweep"; several such notes run together in sharp twitter, especially in interactions. Song, in Costa Rica, a varied high, thin, rapidly delivered medley of slurred whistles, short warbles, chips and weak trills, "see-chew see-chew see-chew seer seer surrtseep, tsee tseew tsewery tseer tsewery sewy tsink-tsink-tsink", with tinkling quality. In Panama, song descriptions similar, songs lasting c. 2 seconds and often given from only a few metres up in small shrub.
Habitat. Bushy and overgrown clearings, dense vegetation along forest borders, hedgerows, flower gardens and cultivated areas around settlements; much less often in canopy of humid montane forest. At 2000–3000 m, seasonally down to 1200 m, in Costa Rica; mostly above 1500 m in Panama.
Food and Feeding. Nectar; also substantial quantities of insects. Occurs singly, in pairs, and occasionally in family groups that includes adult pair and an offspring. Very active; visits wide variety of flowers, both native and introduced species, and is especially fond of certain flowering shrubs and epiphytes. Feeds by hooking upper mandible over, or into, a flower corolla to hold it firm while it uses sharp and slightly upturned lower mandible to puncture base of corolla, and then extracts nectar with its brush-tipped tongue. Foraging movements accomplished with remarkable swiftness, each flower visit lasting little more than a second before the bird flits to another, nearby flower and repeats the process. Also gleans small insects from foliage or chases them in short, quick aerial sorties. Notably territorial; pairs or non-breeding singletons will vigorously defend favourite flower patches against conspecifics, and are, themselves, frequently attacked by hummingbirds (Trochilidae) attempting to use or defend same resources. Often avoid hummingbird attacks by retreating into dense foliage. Reported also as following regular foraging routes in the manner of some "trap-lining" hummingbirds.
Breeding. Following information mainly from studies in Costa Rica. Breeding period centred on second (or longer) rainy season, Aug–Dec, occasional activity extending to Feb and Mar. Nest apparently built entirely by female, male remaining out of sight; nest is a bulky and substantial cup of moss, shredded and decaying leaves and various coarse fibres, even pine needles, lined with finer rootlets, fibres and moss, placed 0·4–4 m up in spiny palm, thick shrub or dense clump of tall grass in pasture. Clutch 2 eggs, light blue, finely speckled with brown, especially in wreath around larger end; incubation period c. 14 days; chicks fed with regurgitated food by both adults, nestling period c. 16 days.
Movements. Largely resident. May wander or migrate seasonally to higher or lower elevations in response to changing abundances of nectar; during year-long study in Costa Rica, however, a pair remained on territory throughout, although flower utilization rates, as well as number of competitive interactions with hummingbirds, varied dramatically.
Status and Conservation. Not globally threatened. Restricted-range species: present in Costa Rica and Panama Highlands EBA. Fairly common to common. Occurs in a number of protected areas, among them Arenal, Poas, Volcán and Chirripó/La Amistad National Parks and Monteverde and Santa Elena Forest Reserves (Costa Rica) and La Amistad and Volcán Barú National Parks (Panama). Also found widely in settled areas. This species appears to be buffered from long-term risks by its ability to live in gardens and settled areas and to exploit many species of plant introduced by humans.
Bibliography. 192. Rusty Flowerpiercer

Diglossa sittoides

French: Percefleur rouilleux **Spanish**: Pinchaflor Ferrugíneo
German: Rostbauch-Hakenschnabel
Other common names: Rusty Flowerpecker

Taxonomy. *Serrirostrum sittoides* d'Orbigny and Lafresnaye, 1838, Valle Grande, Bolivia.
Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Forms a superspecies, and formerly considered conspecific, with *D. baritula* and *D. plumbea*, genetic data suggesting that the three form a monophyletic group. Considerable variation occurs within as well as between races; revision awaited. Six subspecies tentatively recognized.
Subspecies and Distribution.
D. s. hypervthra Cabanis, 1851 – N Colombia (Santa Marta Mts) and N Venezuela (cordillera from Carabobo E to Miranda).

D. s. coelestis Phelps, Sr & Phelps, Jr, 1953 – extreme W Venezuela in Perijá Mts.
D. s. mandeli Blake, 1940 – Mt Turumiquire, in extreme NE Venezuela (Sucre).
D. s. dorbignyi (Boissonneau, 1840) – Andes of Venezuela (Lara S to Táchira) and Colombia (E slope of W Andes and both slopes of C & E ranges).
D. s. decorata J. T. Zimmer, 1930 – Andes of Ecuador and Peru S on both slopes to Bolivia.
D. s. sittoides (d'Orbigny & Lafresnaye, 1838) – Bolivia and NW Argentina (S to vicinity of Tucumán).

Descriptive notes. 11 cm; 7–10·7 g. Small greyish-and-cinnamon flowerpiercer with slender and slightly recurved bill, upper mandible more obviously upturned than lower mandible, upper mandible with sharp hook at tip. Male nominate race is entirely plumbeous grey above, including upperwing-coverts, flight-feathers and tail; slightly darker across forehead, lores, and areas around and behind eye (effect of rather narrow dusky mask); tertials dusky, edged buff to bluish; throat and entire underparts pale cinnamon; iris reddish-brown; bill dusky above, mostly blue-grey below; legs dark grey. Female is medium olive-grey above, wing-coverts and flight-feathers pale-edged, sometimes with more prominent pale buff tips on greater coverts (forming weakly indicated wingbar); pale greyish-olive and largely unstreaked below. Juvenile is similar to female, but usually more obviously streaked and more olive-tinged; immature male variable, some essentially identical to female, others whiter on belly, or with cinnamon tinge on underparts, or with darker, more dusky breast and flanks. Races differ mainly in intensity of plumage colours of male and in intensity of yellow on underparts and extent of streaking of female: *mandeli* is darker above, especially on head, darker and richer below than others, male has crown almost black and obscure bluish tertial edges, female head almost blackish; *hyperythra* is somewhat intermediate, paler than previous but darker than other races, male with pale bluish edges of tertials; *decorata* male is slightly paler above than last and tertials have paler (buffish-white) edges, female brownish above and whitish below, with narrow but distinct streaking on throat, breast and sides, plain brownish flanks; *coelestis* is palest race; *dorbignyi* male has crown decidedly darker than back, female strongly tinged yellowish below and lightly streaked on breast. Voice. Call a sharp "cheek". Song, usually from conspicuous perch on shrub or bush (occasionally a little higher), apparently varies considerably in structure across wide range in Andes: in Peru, Bolivia and Argentina a very fast, metallic rattling "j-j-j-j-j-j-j-jzseeet", rising at end, c. 1 second in duration (though in Peru has been described also as variable in speed); in Colombia (Antioquia) a fast but much more complex song, rising and falling somewhat in pitch, e.g. "p'tzedle'de p'tzedle'de p'tzedle-de-te", the last 2 (or more) notes thin, rising and trailing off; in Ecuador described as variable, either a short thin twitter or a fast series of high-pitched notes followed by lower burry note.

Habitat. Favours shrubby areas, overgrown pastures, forest edges, light open woodland, scrub, bushy hedgerows, and especially flower gardens and shrubs in settled areas, where it utilizes both native and many introduced species as sources of nectar. Dry to humid zones, infrequent inside canopy of mature forest at c. 1500–3000 m; recorded at elevations of 600–3400 m (mostly 1500–2500 m) in Colombia and 1500–2800 m in Ecuador; 1200–3500 m, occasionally down to sea-level, in Peru.

Food and Feeding. Food items include nectar and many small insects. Stomach contents reveal mostly insect remains. Found singly and in pairs, less often in small family groups; may associate with mixed-species flocks along forest borders and in plantations with light woodland, but more often forages apart from flocks. Feeds from near ground to canopy of moderately high trees. Like its allies, a hyperactive species that darts quickly from one flower to the next in quick succession. Spends little more than a second at each flower, then quickly moves to another one nearby, hopping or flitting quickly and keeping mostly out of sight inside dense bushes or shrubs, its head or body appearing briefly beside a flower, then the bird abruptly disappearing. Often leans down to inspect a flower, or hook the flower with upper mandible before puncturing it with its sharp pointed bill. Using its brush-tipped tongue, it extracts nectar through the puncture hole in a movement so quick and deft that it is almost impossible to see. Frequently and sometimes persistently attacked by larger flowerpiercers and by hummingbirds (Trochilidae), to which it responds by quickly fleeing to dense cover, but will reappear as soon as attacks cease; at some nectar sources, will persist in feeding despite attacks from hummingbirds and other competitors. Gleans small insects from foliage or flowers or catches them in short aerial sallies.

Breeding. Fledglings reported in Sept–Feb in Bolivia; juveniles reported almost throughout year in Colombia and in Sept in NW Ecuador; a bird in breeding condition in Apr in Peru (Lima). Holds breeding territory. Builds a deep cup-nest similar to that of *D. plumbea*; clutch 2 eggs, grey to blue with weak greyish spotting, mostly around large end. Male may breed in subadult plumage. No other information.

Movements. Resident. Some seasonal elevational movements likely, but poorly documented.

Status and Conservation. Not globally threatened. Uncommon to fairly common throughout extensive Andean range. Occurs in numerous protected areas, among them Henri Pittier, Guaramacal and Sierra Nevada National Parks (Venezuela), Sierra Nevada de Santa Marta, Puracé and Farallones de Cali National Parks and Río Blanco de Manizales and Reinita Cielo Azul and Tambito Nature Reserves (Colombia), Mache Chindul and Cayambe-Coca Ecological Reserves and Sangay and Podocarpus National Parks (Ecuador), Tingo Maria and Manu National Parks (Peru), Madidi and Amboró National Parks (Bolivia) and Calilegua National Park (Argentina). This species occurs also in many settled areas and flower gardens in rural and urban areas, and is unlikely to face any serious near-term risks.

(2000), Balderrama (2009), Castelino (1999), Clements & Shany (2001), Donegan & Dávalos (1999), Fjeldså & Krabbe (1990), Hackett (1995), Hellmayr (1935), Hilty (1994, 2003), Hilty & Brown (1986), Isler & Isler (1999), Krabbe *et al.* (2001), Mauck & Burns (2009), Meyer de Schauensee (1970a), Miller (1963), Moynihan (1979), Narosky & Yzurieta (1987), Nehrkorn (1899), Ogilvie-Grant (1912), van Oosten (2008), Phelps & Phelps (1950, 1963), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schäfer & Phelps (1954), Schulenberg *et al.* (2007), Taczanowski (1884), Vuilleumier (1969b), Walker (2001), Wetmore *et al.* (1984), Zimmer (1942b).

193. Venezuelan Flowerpiercer

Diglossa venezuelensis

French: Percefleur du Venezuela **Spanish**: Pinchaflor Venezolano
German: Trauerhakenschnabel
Other common names: Venezuelan Flowerpecker

Taxonomy. *Diglossa venezuelensis* Chapman, 1925, Carapas, 5600 feet [c. 1710 m], Sucre, Venezuela.
Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Present species is closely allied to *D. albilatera*. Monotypic.

Distribution. NE Venezuela: Cordillera de Caripe, in N Sucre (from E slope of Cerro Peonía E to Cerro Turumiquire, on Monagas border); also slopes of Cerro Negro (on Sucre–Monagas border), and Cerro Humo (Peninsula de Paría).

Descriptive notes. 12·7 cm. Small flowerpiercer with slender and slightly recurved bill, lower mandible more obviously upturned than upper mandible, upper mandible with sharp hook at tip; resembles more widespread *D. albilatera*. Male has plumage entirely dull black, except for white pectoral tuft and white wing-linings (pectoral tuft almost always visible when bird flicks wings; white on underwing best seen as bird flies); iris dark brown; bill dark; legs grey. Distinguished from very similar *D. albilatera* by black (not slate-coloured) plumage, smaller pectoral tufts, and less white on underwing-coverts. Female has head dark yellowish-olive, upperparts dark brownish-olive, throat and upper chest dull yellowish-olive (paler than crown), this shading to plain dull greyish-olive to brownish-olive on rest of underparts, white pectoral tuft and white wing-linings as on male; much like female of *D. albilatera*, but slightly darker and with less white. Juvenile and subadult male look much like female. Voice. Song a complex but somewhat repetitive series of soft, low-pitched notes uttered rapidly, the entire series lasting up to c. 25 seconds, chattery and rising and falling in pitch several times; not unlike song of *D. major*, but softer and without latter's energy and speed; very unlike song of *D. albilatera*.

Habitat. Borders of humid montane forest, also young to older second growth and shrubby and bushy areas adjacent to forest. At 1525–2450 m in Cordillera de Caripe; 1675–1775 on Cerro Negro; sightings down to 885 m at Melanas, on Paría Peninsula.

Food and Feeding. Diet little known; takes both nectar and small insects. Found singly and in pairs that forage mostly independently of mixed-species flocks. Like congeners, a nervous and hyperactive bird that takes nectar by rapidly piercing bases of flower corollas at almost any height, from near ground to tops of shrubs and trees. Also seen and photographed while foraging low in *Heliconia* thickets.

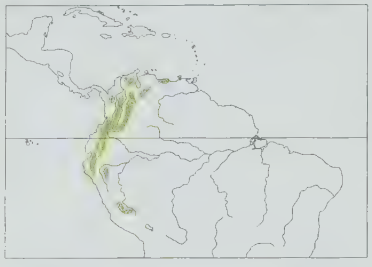
Breeding. No information.

Movements. Resident. Seasonal elevational movements in response to changing nectar resources likely, but undocumented; sightings at 885 m on Paría Peninsula probably refer to such movements.

Status and Conservation. ENDANGERED. Restricted-range species: present in Caripe-Paria Region EBA. Very local; declining. Known only from a small number of localities in extreme NE Venezuela. Known to occur in Paría Peninsula and El Guácharo National Parks. Areas where it could still occur include Cumbres de San Bonifacio, Serranía de Turumiquire and Cerro Humo. Widespread deforestation for agriculture and cattle pastures evident in Cordillera de Caripe, and extensive forest damage taking place even in El Guácharo National Park. Most of Cerro Negro now completely denuded or devoted to shade coffee plantations. In Serranía de Turumiquire, deforestation for coffee, bananas, mango and citrus is occurring, although considerable intact forest still present. Cerro Humo faces similar forest degradation and uncontrolled burning. Extent to which this species is able to survive in areas of regrowth vegetation or in coffee plantations, which increasingly threaten to overwhelm almost all of the native forest remaining in its range, is not known. Other members of its genus tend to thrive, or at least survive, in cultivated areas and gardens with flowers, even in settled areas, but that seems not to be the case with present species and an assessment of its habitat requirements is needed urgently. A fairly large number of specimens were taken from Cerro Turumiquire as recently as 1963, but the number of sightings since that time is small. A recent paved road from Güiria to tip of Paría Peninsula (at Macuro) will almost certainly lead to loss of habitat as human settlement follows. A proposed gas pipeline over Paría Peninsula, running from gas fields on N shore to cryogenics facilities on S shore, represents an additional serious threat.

Bibliography. Anon. (2010a), Boesman & Curson (1995), Butchart & Stattersfield (2004), Collar *et al.* (1992), Hilty (2003), Isler & Isler (1999), Meyer de Schauensee & Phelps (1978), Restall *et al.* (2006), Ridgely & Tudor (1989, 2009), Stattersfield & Capper (2000).

194. White-sided Flowerpiercer



Diglossa albilatera

French: Percefleur à flancs blancs **Spanish**: Pinchaflor Flanquiblanco
German: Schieferhakenschnabel
Other common names: White-sided Flowerpecker

Taxonomy. *Diglossa albi-latera* Lafresnaye, 1843, Santa Fé de Bogotá, Colombia.
Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Present species is closely allied to *D. venezuelensis*. Four subspecies recognized.

Subspecies and Distribution.
D. a. federalis Hellmayr, 1922 – coastal cordillera of N Venezuela (from Aragua E to Distrito Federal and Vargas, probably also adjacent Miranda).
D. a. albilatera Lafresnaye, 1843 – Sierra de Perijá (Colombia–Venezuela border), Andes of Venezuela (from Lara S to Táchira), and Colombia in Sierra Nevada de Santa Marta and all three ranges of Andes S to S Ecuador (except extreme SW) and probably to N Peru (Cajamarca).
D. a. schistacea Chapman, 1925 – extreme SW Ecuador and NW Peru W of R Marañón.
D. a. affinis J. T. Zimmer, 1942 – Peru from R Utcubamba watershed in Amazonas (E of R Marañón) and on W slope in Ayacucho S to NW Cuzco.

Descriptive notes. 12 cm; male 8·5–12·7 g, female 8–11·4 g (Colombia). Small flowerpiercer with thin, short and somewhat upturned bill, upper mandible with distinct hook at tip, lower mandible slender, sharply pointed and more obviously upturned. Male nominate race is dark slate-grey above and below, with elongated, partly concealed tufts of silky-white feathers on each side of body

(visible as flashes of white as bird flicks wings); underwing-coverts white; iris dark brown; bill entirely blackish, sometimes paler at base of lower mandible; legs grey. Female is plain olive-brown above, paler below, with obvious cinnamon tinge on most of underparts, but slightly more yellowish-buff on belly, and undertail-coverts tinged rufescent; no pale edges on wing feathers, or occasionally some pale edging on greater wing-coverts (forming one faint wingbar); underwing-coverts and elongated feathers of sides silky white, as on male. Juvenile is like female, but faintly scaled and with belly whitish; immature male like female, but duller, underparts broadly washed buff, and breast obscurely streaked darker. Race *federalis* male differs from nominate in decidedly paler and greyer plumage, female is paler overall, more olive-tinged above and much more yellowish buff below than nominate and with cinnamon wash paler and more confined to chest and sides; *schistacea* male is similar to nominate, but paler, bluish-slate, above and below and with bluish gloss to plumage; *affinis* male is much like previous, but has on average longer wing and tail, and plumage darker, especially on upperparts, and without bluish colour, female differs from nominate female in slightly larger size, more brownish (less olive) upperparts and warmer, less ochraceous throat and breast. Voice. Song in Venezuela 1–2 high shrill notes followed by lower-pitched rattle-trill of even pitch and strength, "swéé-ti ti'ti'ti'ti'ti'ti' ti'ti'ti'ti", entire song lasting just over 1 second; in N cordillera (Venezuela) typically a high, thin, tinny trill descending slightly, then a flat rattle, "ti ti ti ti ti ti ti ti ti ti ti ti ti ti te'te'te'te'te'te'te". When disturbed gives a flat buzzy trill, much faster than song and sometimes rising slightly in pitch. Elsewhere in range, song described as a fairly loud flat trill usually preceded by 2 faint notes.

Habitat. Exhibits fondness for flowering vines, and occurs in humid overgrown clearings, shrubby forest edges, stunted cloudforest, cultivated areas and highland gardens, even suburban areas. At c. 1600–2800 m, but most numerous in lower half of this elevational range, somewhat higher in S, where generally less numerous; recorded as low as 1200 m in N Colombia (Santa Marta Mts), and down to 1550 m in Ecuador; 1650–3000 m in Peru.

Food and Feeding. Nectar; probably also insects. Forages singly or in loose pair, or occasionally a family of three seen together; follows mixed-species flocks or, more often, forages independently of them. Restless and hyperactive, constantly flicking wings and exposing patch of white beneath each wing. Moves somewhat furtively along dense forest borders from below eye level to canopy, mostly in middle levels. Adept as staying out of sight inside dense shrubs, then popping into view briefly to pierce a flower corolla. Repeatedly appears briefly and then disappears inside dense shrubbery as it moves from one flower to the next, pausing for little more than a second at each to puncture the flower for nectar, or to revisit holes previously punched into flower corollas. In some areas visits nectar feeders.

Breeding. Fledglings reported in Nov and Apr, immatures in Jul and Dec and birds in breeding condition in Apr–Aug in Colombia; eggs in Mar and fledglings in Apr and Oct in Ecuador; and fledglings in Jul and immatures in Jul and Sept in Peru. One nest found in Ecuador, a compact open cup of moss, grass and rootlets, placed 0·8 m up in clump of dense small bamboo shoots; in Colombia, cup-nest of moss, lichens and fern fragments, up to c. 5 m above ground. In Ecuador, eggs blue or greenish-blue, thickly speckled with brown, especially around larger end; no information on clutch size. No other information.

Movements. Poorly documented. Presumed resident, but some seasonal wandering (or possibly regular migratory movements) to higher and lower elevations likely.

Status and Conservation. Not globally threatened. Fairly common. Widespread in more open, sunny, montane habitats where flowering shrubs and bushes present. Found in many protected areas, among them Henri Pittier, Macarao, Yacambú, Guaramacal and Sierra Nevada National Parks (Venezuela), Sierra Nevada de Santa Marta, Chingaza, Las Orquídeas, Farallones de Cali and Cueva de los Guácharos National Parks and Reinita Cielo Azul and Tambito Nature Reserves (Colombia) and Cotocachi-Cayapas Ecological Reserve and Sangay and Podocarpus National Parks (Ecuador). This species' ability to utilize bushy clearings and flower gardens in settled areas buffers it, in large measure, from near-term risks.

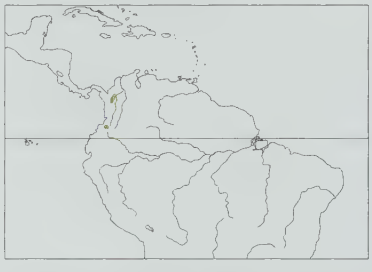
(2000), Burns & Racicot (2009), Donegan & Dávalos (1999), Fjeldså & Krabbe (1990), Greeney (1999), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Krabbe *et al.* (2001), Mauck & Burns (2009), Mazar Barnett *et al.* (2006), Moore *et al.* (1999), Moynihan (1979), Nehrkorn (1899), Ogilvie-Grant (1912), Restall *et al.* (2006), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schäfer & Phelps (1954), Schulenberg (2000b), Schulenberg *et al.* (2007), Sclater & Salvin (1879), Skutch (1954), Snow & Snow (1980), Strewe & Navarro (2004), Todd & Carriker (1922).

195. Chestnut-bellied Flowerpiercer

Diglossa gloriosissima

French: Percefleur à ventre marron **Spanish**: Pinchaflor Ventrirrufo
German: Maronenbauch-Hakenschnabel
Other common names: Chestnut-bellied Flowerpecker

Taxonomy. *Diglossa gloriosissima* Chapman, 1912, Andes, west of Popayán, 10,340 feet [c. 3150 m], Cauca, Colombia.



Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. This species forms a superspecies with *D. lafresnayii* and *D. mystacalis*, and all formerly considered conspecific; molecular-genetic data indicate that present species and *D. mystacalis* are more closely related to each other than either is to *D. lafresnayii*. Two subspecies recognized.

Subspecies and Distribution.

D. g. boylei G. R. Graves, 1990 – Nudo de Paramillo (in Municipio de Ituango) and Urrao (on Páramo Frontino), in N Antioquia (Colombia).

D. g. gloriosissima Chapman, 1912 – El Tambo, on Cerro Munchique (Cauca), in Colombia.

Also, in Antioquia, one individual near Jardín (33 km NW of Citará) and two additional specimens at Páramo de Citará, all three probably referable to race *boylei*.

Descriptive notes. 14 cm; two birds each 14 g. Medium-sized, chestnut-bellied flowerpiercer with bill somewhat upturned and strongly hooked at tip. Male nominate race is mainly lustrous black above and below, with lesser and median upperwing-coverts silvery-blue (forming small, triangular-shaped shoulder patch), uppertail-coverts lustrous black, suffused with slate-grey (usually concealed and barely discernible); middle of breast to belly and undertail-coverts rich rufous-chestnut, sides sometimes indistinctly mottled with black; iris dark brown; bill black except for pale blue-grey line at base of lower mandible; legs dark grey. Sexes similar. Juvenile has plumage pattern similar to that of adult, but much duller, head, throat and upperparts dingy dark brown (not black), duller paler rufous of lower underparts variably mixed with dark brown. Race *boylei* is similar to nominate, but rump and uppertail-coverts slightly more contrasting, dark grey to bluish-grey, and sides cleaner rufous-chestnut. Voice. Song notably slower and lower-pitched than that of most congeners, a leisurely to moderately brisk series of high, penetrating, semi-musical notes mixed with hard, slightly metallic ones, rising and falling in complex (patterned?) manner, e.g. "chut, chet-chet-chee-sa'wee, sa-wee-tu-tu-tslee-chet-tslee, chet, chet chee, chut, sa-wee...", may continue uninterrupted for nearly 30 seconds, then slow and, following a few hesitant random notes, song may start again; "chet-chet-chee" or similar 3-note phrase repeated frequently in song.

Habitat. Near tree-line in humid and wet montane scrub and elfin forest, and ranges only short distance above or below this tree-line ecotone; probably tolerates some amount of habitat degradation. At c. 3000–3800 m.

Food and Feeding. No information; probably similar to *D. lafresnayii*. At Páramo Frontino (race *boylei*) believed to compete with *D. brunneiventris*, the two species apparently holding mutually exclusive territories.

Breeding. No information.

Movements. No information.

Status and Conservation. ENDANGERED. Restricted-range species: present in Chocó EBA. Until recently known from three localities, two of them at N end of W Andes in Antioquia (Páramo Frontino and Cerro Paramillo) and a third at lower elevation and far to S in Cauca (Cerro Munchique). Recorded at Páramo Frontino in 1965, but thereafter went unreported for almost 40 years. In 2003, recorded (specimen) at an unpublished site near Jardín, in Antioquia, and in 2004 rediscovered at type locality (ten observed and three collected), as well as at a new locality, Farallones del Citará, 70 km to S; at last-named site, three were captured in nets and three others seen. Small number of records, at least of N population, doubtless reflects lack of fieldwork because of difficulty of reaching these remote mountain-top sites, and because of security problems, which have plagued the region. Rare, but found to be fairly common very locally at type locality (Páramo Frontino). Periodic fires in *páramo*, as well as cattle-rearing and other agricultural activities, including livestock grazing, are key threats; estimated that the species has already lost 17% of its habitat. On the positive side, both the N and the S populations lie partly within national reserves, Paramillo National Park (in N) and Munchique National Park (in S), although maintaining the integrity of the parks is an ongoing problem. Also on the positive side, although no estimates of total population available, recent fieldwork indicates that the species is relatively numerous within the pockets of habitat where it occurs. Its small natural range and naturally fragmented distribution place this species at risk. Human settlement and associated deforestation and burning near Cerro Paramillo, and a communications facility and military activity near top of Cerro Munchique, are considered threats. Burning of diverse *páramo* vegetation and its replacement with pasture grasses may also be a significant threat.

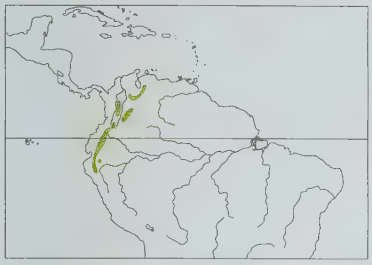
PLATE 22 ➤



196. **Glossy Flowerpiercer**

Diglossa lafresnayii

French: Percefleur de Lafresnaye **German**: Stahlhakenschnabel **Spanish**: Pinchaflor Satinado
Other common names: Glossy Flowerpecker

Taxonomy. *Uncirostrum La Fresnayii* Boissonneau, 1840, Santa Fé de Bogotá, Colombia.
Genus has sometimes been placed in Cœrebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. This species forms a superspecies with *D. gloriosissima* and *D. mystacalis*, and all formerly considered conspecific; molecular-genetic data indicate that *D. gloriosissima* and *D. mystacalis* are more closely related to each other than either is to present species. Monotypic.

Distribution. Andes of Venezuela (S from Trujillo) S to Colombia (Norte de Santander; isolated population in Cundinamarca, in E Andes; C range from Antioquia S to Quindío and Tolima, and in S from E Cauca and Huila) S through Ecuador to N Peru (Cajamarca).
Descriptive notes. 14·5 cm; 13·1–19 g. Fairly large, all-black flowerpiercer with decidedly upturned bill hooked at tip, lower mandible sharply pointed. Plumage is almost entirely glossy black above, with marginal coverts and lesser upperwing-coverts contrastingly pale blue-grey (forming small triangular patch on shoulder, sometimes partly hidden), forehead to supercilium more velvety-black; flight-feathers, tail and underparts more or less unglossed black, or some gloss on breast and sides; iris deep reddish-brown; bill black, basal half of lower mandible pale grey; legs dark grey. Differs from closely similar *D. humeralis* mainly in having larger blue-grey shoulder patch, also in larger size, larger and heavier bill, and glossy plumage. Sexes similar. Juvenile and immature are brownish-black, with shoulder patch faint. Voice. In Venezuela song an exuberant stream of rapid chattering and chipping notes, "chit'chat'chip'chat' chip'chip'cheet'chit..." and so on for up to a minute or more, colourless, rather directionless and rising and falling, with little evident pattern (some songs with galloping pattern); some appear to be sung more or less simultaneously as a duet (possibly antiphonal) by partners. Songs described from Peru seem to be similar, a variable series

of single and double notes, some thin, some louder, that stumble along for minutes. In E Andes of Colombia, song described as a series of thin high notes in groups of 3–4, at times the series very prolonged, "chip chip chiiu chip chip chiu" etc. or "chii chichi chiiu chii...", often given when perched in the open at end of small branch (after which it usually disappears inside vegetation). At dawn, often sings from favourite location at top of a shrub. Both sexes sing.

Habitat. Humid and shrubby montane thickets and stunted and mossy forest up to tree-line; also thrives in disturbed habitats such as overgrown pastures, hedgerows and flower gardens at lower elevations. At c. 2000–3750 m (tree-line), most records at c. 2700–3700 m. In E Andes of Colombia most numerous at high elevations in *subpáramo* and stunted vegetation, but at lower elevations, in settled areas, flower gardens and disturbed areas, greatly outnumbered by *D. humeralis*.

Food and Feeding. Nectar and insects. Regularly follows mixed-species flocks, but also often forages independently of them. Can be particularly furtive and secretive as it wiggles through dense shrubbery, popping into view momentarily, then disappearing almost immediately; although it sings in the open at dawn, it otherwise tends to remain out of sight during the day, and stays low when flying between shrubs or crossing open spaces. Regularly visits hummingbird feeders for nectar in Ecuador. Like other members of genus, actively punctures bases of flowers for nectar and often revisits punctured flowers; also forages for small insects, which it sometimes chases in short quick aerial sallies. Pair defends a common territory when breeding, but at other times of year holds individual territories, which it vigorously defends.

Breeding. In Colombia, fledgling in Mar, juvenile/immature in Jul and birds in breeding condition in Feb–Jul. Nest a cup built from moss and plant fibres, lined with finer plant material, overall more bulky than nest of *D. humeralis*; placed 1–2 m up in dense bush or clump of bamboo. No other information.

Movements. Apparently resident. Little definite information. Some seasonal movements to higher or lower elevations may occur when nectar resources low.

Status and Conservation. Not globally threatened. Fairly common over most of range; inconspicuous. Occurs in a number of protected areas, among them Sierra Nevada and Tamá National Parks (Venezuela), Tamá, Chingaza, Nevado de Tolima and Puracé National Parks (Colombia), Cotopaxi, Sangay and Podocarpus National Parks (Ecuador) and possibly Cordillera de Colán National Park (Peru). Important threats within its range include widespread burning, cattle grazing and wood-cutting in upper montane-*páramo* ecotone areas. Like many congeners, this species is buffered to some extent by its ability to utilize areas with human settlement and disturbance.

Bibliography. Álvarez-Rebolledo & Córdoba-Córdoba (2002), Anon. (2000), Burns (1997a), Burns *et al.* (2002, 2003), Clements & Shany (2001), Fjeldså & Krabbe (1990), Graves (1982a), Hellmayr (1935), Hilty (2003), Hilty & Brown (1986), del Hoyo (2005), Isler & Isler (1999), Koenen & Koenen (2000), Krabbe *et al.* (2001), Martin, P.R. *et al.* (2009), Mauck & Burns (2009), Meyer de Schauensee (1970a), Moynihan (1963b, 1979), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Vuilleumier & Ewert (1978).

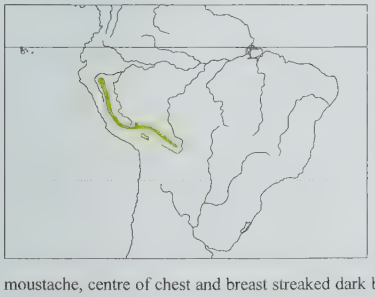
197. Moustached Flowerpiercer

Diglossa mystacalis

French: Percefleur moustachu **German**: Barthakenschnabel **Spanish**: Pinchaflor Bigotudo
Other common names: Moustached Flowerpecker

Taxonomy. *Diglossa mystacalis* Lafresnaye, 1846, yungas of La Paz, Bolivia.

Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. This species forms a superspecies with *D. gloriosissima* and *D. lafresnayii*, and all formerly considered conspecific; molecular-genetic data indicate that *D. gloriosissima* and present species are more closely related to each other than either is to *D. lafresnayii*. Four subspecies recognized.



Subspecies and Distribution.

D. m. unicincta Hellmayr, 1905 – N Peru on E Andean slope from S Amazonas and La Libertad S to Huánuco (W & N of R Huallaga), also locally on W slope of E cordillera in Marañón Valley.

D. m. pectoralis Cabanis, 1873 – C Peru on E Andean slope from C Huánuco (E of R Huallaga) S to Pasco and Junín.

D. m. albilinea Chapman, 1919 – SE Peru (Ayacucho, Cuzco and Puno).

D. m. mystacalis Lafresnaye, 1846 – Bolivia (La Paz, Cochabamba and W Santa Cruz).

Descriptive notes. 14·5 cm; 12–19·2 g, four birds 16–16·5 g (*albilinea*). Fairly large flowerpiercer with distinctive throat pattern; bill proportionately longer, straighter and less clearly hooked than that of smaller members of genus. Nominate race is mainly glossy black, with rufous moustache, small pale blue shoulder patch and rufous-tinged undertail-coverts; upperwing-coverts slightly glossed, flight-feathers and tail dull black to blackish; iris dark brown; bill black; legs dark grey. Sexes similar. Juvenile (race *unicincta*) is mainly dark brown above, with forecrown, side of head and upperwing-coverts dusky brown, throat dusky, with irregular white moustache, centre of chest and breast streaked dark brown, sides and flanks dark brown, central lower underparts and undertail-coverts buffy rufous, basal half of lower mandible dull pinkish-yellow; immature (all races) similar to adult, but duller; subadult somewhat streaky, with white on breast. Races differ mainly in pattern of markings on throat and chest: *albilinea* is similar to nominate, but with moustache white (sometimes stained buff distally) and rufous vent and undertail-coverts; *unicincta* has prominent white moustache extending as a broad rufous arc across chest, has vent and undertail-coverts strongly rufous; *pectoralis* is similar to last, but lower part of pectoral band white, and lacks pale shoulder patch. Voice. Song, heard mostly at dawn, typically from exposed position at top of shrub or low tree, a rather strong, vigorous, even strident series of rising and falling notes, 4–5 per second, lasting for a few seconds or up to several minutes and given at relatively even volume.

Habitat. Stunted, humid montane woodland, low cloudforest, elfin forest, and patches of woody shrubs and *Polylepis* in lower *páramo*; also drier scrubby woodland in S part of range. At c. 2400–3700 m (in Peru), and recorded to 4000 m, but most numerous near tree-line.

Food and Feeding. Unlike its smaller congeners, rather insectivorous; also takes nectar from wide variety of flowers. Usually singly and often with mixed-species flocks containing small tyrant-flycatchers (Tyrannidae), other tanagers and New World warblers (Parulidae). Forages at middle levels or higher by moving in and out of dense foliage, disappearing and then reappearing.

Breeding. Fledglings in Aug in N Peru (Amazonas) and juveniles and immatures seen throughout year in both Peru and Bolivia. No other information.

Movements. No information. Because of greater dependence on insects than are its smaller allies, may be less inclined to engage in seasonal movements.

Status and Conservation. Not globally threatened. Uncommon to fairly common. Occurs in a few protected areas, among them the Machu Picchu Historical Sanctuary, Manu National Park and probably Huascarán National Park (Peru) and Madidi National Park (Bolivia). This species' range includes extensive unprotected, tree-line habitat that is under constant pressure from firewood-cutting and burning, and is at risk locally.

Bibliography. Clements & Shany (2001), Fjeldså & Krabbe (1990), Graves (1982a), Hellmayr (1935), Isler & Isler (1999), Mauck & Burns (2009), Meyer de Schauensee (1970a), Moynihan (1979), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Schulenberg *et al.* (2007), Walker (2001), Weske (1972).

198. Merida Flowerpiercer

Diglossa gloriosa

French: Percefleur de Mérida **German**: Méridahakenschnabel **Spanish**: Pinchaflor de Mérida
Other common names: Merida Flowerpecker

Taxonomy. *Diglossa gloriosa* P. L. Sclater and Salvin, 1871, Paramo de la Culata, north of Mérida, Venezuela.

Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Present species forms a monophyletic group with *D. humeralis*, *D. brunneiventris* and *D. carbonaria*, and all were previously regarded as conspecific. Monotypic.

Distribution. Andes of Venezuela (Trujillo, Mérida, and Táchira N of the Táchira gap).

Descriptive notes. 13·5 cm; 11–11·5 g. Medium-sized chestnut-bellied flowerpiercer with slender and somewhat upturned bill with prominent hook at tip. Has head, throat, chest, side of neck and most of upperparts deep black (not glossy), bluish-grey rump and uppertail-coverts usually concealed; short and inconspicuous bluish-grey superciliary stripe, some individuals also with traces of rufous malar; marginal and lesser upperwing-coverts blue-grey, forming narrow triangular patch on shoulder; breast, belly and undertail-coverts rufous-chestnut, flanks grey (usually visible); iris dark brown; bill black, basal half of lower mandible pale grey; legs dark grey. Sexes similar. Juvenile is dingy greyish-brown above, somewhat mottled and streaked on back, dark brown median and greater upperwing-coverts with buff edges and tips, flight-feathers dusky brown, inner feathers and tertials edged buff, throat dingy brown, becoming paler and buffier on lower underparts and with throat and breast streaked dark brown; immature dusky brown above, sometimes with hint of pale malar and pale edging on wing-coverts, dark brown throat and chest streaked buff, rusty-buff lower underparts somewhat streaked dusky; older birds show more clear separation of dark throat, and variable amount of rufous appearing on lower underparts. Voice. Virtually nothing known. One vocalization a long trill.

Habitat. Dry and open or semi-open scrubby areas in highlands, including cultivated areas, flower gardens, hedgerows, stunted montane thickets and low, wooded borders, from well below tree-line to far above it in *páramo*; rare or absent in humid areas. At 2500–4150 m.

Food and Feeding. Nectar and insects. Occurs in pairs when breeding, but otherwise usually seen singly; occasionally associates with mixed-species flocks, but more often found alone. Nervous-acting and highly strung, but not so furtive as *D. lafresnayii* and usually easy to observe. Works rapidly and quickly through dense shrubbery and flowering bushes; keeps low when flying across openings, and often returns again and again to favourite patches of flowers. Pugnacious in defending joint feeding territory when breeding; at other times defends individual territory. Often harassed by hummingbirds (Trochilidae), especially larger species such as Golden Starfrontlet (*Coeligena eos*); eludes attacks by ducking head or retreating momentarily into dense shrubbery, or, in persistent attacks, by leaving the area. Behaviour much like that of *D. humeralis*, *D. brunneiventris* and *D. carbonaria*.

Breeding. One nest believed to have been of this species found in Apr; a deep cup of grass and moss placed atop a bank. No other information.

Movements. Resident. Given strongly seasonal nature of flowering in much of high Andes in Venezuela, some local seasonal movements in response to changing food abundances seem likely.

Status and Conservation. Not globally threatened. Restricted-range species: present in Cordillera de Mérida EBA. Locally common. Occurs in several protected areas, including Guaramacal, Sierra de la Culata, Páramos del Batallón y La Negra, Sierra Nevada and probably Dinira National Parks. Although total range occupied by this species is small, it is buffered against serious risk by its ability to utilize a variety of degraded or altered habitats in settled areas if flowers present. Particularly attracted to flower gardens in both rural and urban areas.

Bibliography. Fjeldså & Krabbe (1990), Graves (1982a, 1991), Hellmayr (1935), Hilty (2003), Isler & Isler (1999), Kjonaas & Rengifo (2006), Mauck & Burns (2009), Meyer de Schauensee (1970a), Meyer de Schauensee

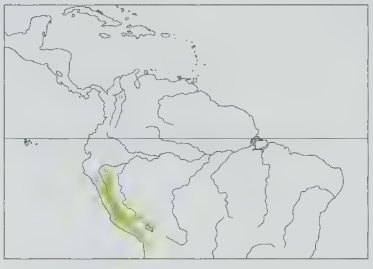
199. **Black Flowerpiercer**

Diglossa humeralis

French: Percefleur noir **German**: Schwarzbauch-Hakenschnabel **Spanish**: Pinchaflor Negro
Other common names: Black Flowerpecker; All-black Flowerpiercer/Flowerpecker (*aterrima*); Santa Marta Flowerpiercer (*nocticolor*)

Taxonomy. *Agrilorhinus humeralis* Fraser, 1840, Santa Fé de Bogotá, Colombia.
Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Present species forms a monophyletic group with *D. gloriosa*, *D. brunneiventris* and *D. carbonaria*, and all were previously regarded as conspecific. Three subspecies recognized.
Subspecies and Distribution.
D. h. nocticolor Bangs, 1898 – Santa Marta Mts, in N Colombia, and Perijá Mts, on Colombia–Venezuela border.
D. h. humeralis (Fraser, 1840) – SW Venezuela (S Táchira S of the Táchira gap) and adjacent E Andes of Colombia (from Norte de Santander S to Cundinamarca, probably to Nariño).
D. h. aterrima Lafresnaye, 1846 – Andes of Colombia (S from N Antioquia in C range, from Cerro Munchique, in Cauca, in W range), Ecuador and N Peru (S to Marañón Valley).



Descriptive notes. 13·7 cm; 9·6–14·3 g, male 12–15·4 g and female 12·4–13·6 g (Colombia). Medium-sized black flowerpiercer with slender and somewhat upturned bill with prominent hook at tip. Nominate race is almost entirely dull black above, rump more dark grey (visible only in hand), with small blue-grey shoulder patch (marginal coverts and lesser upperwing-coverts); some individuals have faint grey barring on uppertail-coverts and undertail-coverts, flanks and belly, and some have chestnut undertail-coverts and/or faintly indicated pale supercilium; iris reddish-brown; bill black, basal half of lower mandible pale grey; legs dark grey. Differs from extremely similar *D. lafresnayii* in slightly smaller size, smaller bill, and mainly matt black (not glossy) plumage with smaller blue-grey shoulder patch. Sexes similar. Immature is greyish-brown, indistinctly streaked dusky, underparts paler and more prominently streaked. Race *aterrima* has rump black, lacks blue shoulder patch, never has pale supercilium and/or chestnut undertail-coverts; *nocticolor* is very like previous, but rump dark grey. Voice. Song, from atop low shrub or bush, also from well up in tall tree, a jumbled stuttering and twittering, resembles that of *D. lafresnayii*, but faster, in Bogotá area (Colombia) sharp and rapid, 2–4 thin notes followed by one or two rapid trills, "tsi-tsi-tsrrr-sirrt-t" etc. or "psi-si-psit-tsrrrrrr" etc.; song sometimes a mix of fast, high-pitched and unmusical trills and short notes. Both sexes sing. Call a thin "sit" or "tsi", high-pitched and fine; occasionally a rough "friiiiiii".
Habitat. Humid montane regions. Occurs in stunted elfin forest, shrubby borders and sheltered wooded ravines at or near tree-line, occasionally in *Polylepis* and low shrubs well above tree-line, but more commonly in hedgerows, parks, flower gardens and other cultivated areas with shrubbery in settled areas at lower elevations, including large urban settings (e.g. Bogotá), where *D. lafresnayii* scarce. At 2175–3300 m, mostly above 2700 m, in Venezuela; elsewhere 1500–4000 m (mostly 2200–3400 m in Colombia, 2200–4000 m in Ecuador, 1850–3300 m in Peru).
Food and Feeding. Nectar, also insects. Behaviour generally similar to that of *D. lafresnayii*, but, unlike that species, infrequently with mixed-species flocks. Forms pairs briefly for breeding, but otherwise individuals aggressively defend solitary territories with flowers against both conspecifics and other nectar-feeders, including congeners, hummingbirds (Trochilidae) and *Conirostrum* conebills. Highly active when foraging, but keeps mostly inside dense shrubbery and out of sight, often for extended periods of time, and generally attempts to avoid competitive conflicts with hummingbirds by retreating inside dense shrubs. Takes nectar from flowers by puncturing base of corolla, as well as probing flowers directly from outside; takes insects from foliage and flowers, also in short quick aerial sallies.
Breeding. Juveniles and immatures reported virtually throughout year and birds in breeding condition in Feb–Sept in Colombia. Nest in Ecuador a cup made from rootlets and moss, suspended 0·8 m up from thorns of sword-like aloe leaf (*Aloe*); in Colombia well hidden 1–4 m up in bush, shrub or bamboo. Clutch in Ecuador 2 eggs, blue, speckled with red, in Colombia eggs clear blue or speckled brown. No other information.
Movements. Not well documented. Highly territorial; seasonal movements in response to changing resources may be mostly local.
Status and Conservation. Not globally threatened. Locally common. Can be found in numerous protected areas, among them Tamá National Park (Venezuela), Sierra Nevada de Santa Marta, Tamá, Chingaza, Los Nevados, Nevado de Huila and Puracé National Parks (Colombia), Cotopaxi, Cajas, Sangay and Podocarpus National Parks (Ecuador) and probably Cordillera de Colán National Park (Peru). Deforestation, burning and firewood-cutting are important threats to the natural habitat of this species, although it adapts well to settled areas wherever there are parks and gardens with flowers; unlikely to face serious risks in the near future.
Bibliography. Anon. (2000), Clements & Shany (2001), Fjeldså & Krabbe (1990), Goodfellow (1901), Graves (1982a, 1991), Hellmayr (1935), Hilty (1994, 2003), Hilty & Brown (1986), Isler & Isler (1999), King (1990), Koenen & Koenen (2000), Krabbe *et al.* (2001), Mauck & Burns (2009), McCarthy (2006), Moynihan (1963b, 1979), Phelps & Phelps (1950), Remsen *et al.* (2010), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Taczanowski (1884), Vuilleumier (1969b).

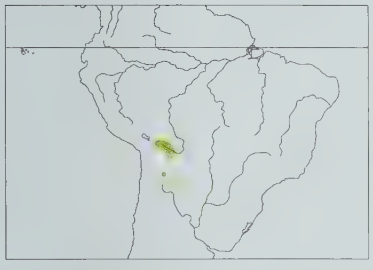
200. **Black-throated Flowerpiercer**

Diglossa brunneiventris

French: Percefleur à gorge noire **Spanish**: Pinchaflor Gorjinegro
German: Schwarzkehl-Hakenschnabel
Other common names: Black-throated Flowerpecker; Vuilleumier's Flowerpiercer (*vuilleumieri*)

Taxonomy. *Diglossa brunneiventris* Lafresnaye, 1846, Peru.
Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Present species forms a monophyletic group with *D. gloriosa*, *D. humeralis* and *D. carbonaria*, and all were previously regarded as conspecific; known to hybridize, to limited extent, with *D. carbonaria* in small area of range overlap in Bolivia (La Paz). Isolated N race *vuilleumieri*, two populations of which are separated by c. 1500 km from larger nominate race in S, occurs in very humid zones, whereas nominate mainly in dry to arid zones, and song of at least W population of *vuilleumieri* (on Páramo Frontino) differs markedly from that of nominate (though specimens of the two are so similar that many, if not most, are racially inseparable); further taxonomic investigation required. Two subspecies recognized.
Subspecies and Distribution.
D. b. vuilleumieri G. R. Graves, 1980 – Antioquia (N end of W Andes and N end of C Andes), in Colombia.
D. b. brunneiventris Lafresnaye, 1846 – N Peru from S Cajamarca (S of R Marañón) S on W Andean slope to extreme N Chile (Tarapacá) and S on E slope to W Bolivia (La Paz).

Descriptive notes. 14 cm; 9·8–15 g. Medium-sized chestnut-bellied flowerpiercer with slender and somewhat upturned bill with prominent hook at tip. Nominate race is mainly black above, including crown, side of head, most of upperparts, most of wing, and entire tail; rump and uppertail-coverts rather pale grey, marginal coverts and lesser upperwing-coverts pale bluish-grey (forming small triangular patch on shoulder, sometimes partly concealed by scapulars), variable number of scapulars sometimes pale grey; centre of throat black, bordered by prominent rufous submoustachial stripe, latter continuous with deep rufous underparts; sides and flanks light blue-grey, partly concealed by wing (but always visible), thigh black; iris dark reddish-brown; bill black, basal half of lower mandible pale grey; legs dusky grey. Sexes similar. Juvenile is dusky olivaceous brown above, usually with some very faint dusky streaking, has two cinnamon-coloured wingbars and wing edgings, narrow moustachial streak buff to greyish, throat and underparts buff; immature like juvenile, but wing-coverts and wing edgings dull greyish, underparts streaked dusky, some immatures (possibly subadults) cinnamon-rufous below with dusky streaks and spots. Race *vuilleumieri* is very like nominate, but slightly larger in body size, with slightly larger black throat patch. Voice. Both sexes sing. In Peru, song is a fast complex series of notes, duration 1·5–4 seconds, described as a rapid jumble of warbling notes. At dawn typically, perches in open in top of shrub or small tree for extended periods to sing; rarely, song given also in flight. Call a thin "zit" and various wheezy notes. Song of *vuilleumieri* (at N end of W Andes) distinctive, consisting of three parts, a short, very flat and loose, low-pitched rattle, blending into brief slightly rising, complex phrase, and terminating with a longer, slightly higher-pitched rattle, the three parts run together without a noticeable break, e.g. "tw'tw'tw'tw'st'sle't'te'te'te'te'te'te'te'te'te'te".
Habitat. Humid elfin forest and montane–*páramo* ecotone in Colombia (race *vuilleumieri*). In Peru, W Bolivia and N Chile found mainly in dry to arid scrub at high elevation, and also, in much smaller numbers, in semi-humid or humid regions; wooded borders, hedgerows, cultivated and agricultural areas, including rather severely degraded regions so long as some scrub vegetation remains; also bushy streamside and in *Polylepis* above tree-line. Most numerous in dry low-stature montane scrub, especially with *Brachyotum* (Melastomataceae), *Gynoxys* (Asteraceae), second growth, gardens and even exotic eucalypts (*Eucalyptus*). Apparently c. 2000–3900 m in Colombia; 2400–4300 m (occasionally down to 2000 m) in Peru.
Food and Feeding. Following information based on studies of nominate race; N race (*vuilleumieri*) very poorly known in life. Diet nectar and insects. In pairs when breeding, but otherwise holds individual territory, which vigorously defended against other small nectar-feeders. Occasionally forages through shrubby areas with small mixed-species parties containing *Conirostrum* species and other tanagers, New World warblers (Parulidae) and tyrant-flycatchers (Tyrannidae), but more often seen alone or in pairs. Forages at all heights, from near ground, occasionally even on ground, to tops of shrubs and small trees. Very active; flicks wings, twists and turns and works through dense vegetation or flies low between patches of scrub. Although adept at keeping out of sight, is much less furtive than some others of genus, e.g. *D. lafresnayii* and *D. humeralis*. May cling or hang downwards if necessary to reach flowers. Punctures tubular corollas of a wide variety of small flowers, moving rapidly from one to the next and pausing little more than a second at each; regularly revisits puncture holes for nectar. Also forages for insects on foliage and in flowers, and makes quick aerial sorties for flying insects. Also probes flowers directly through front of corolla (without piercing), and reported as being a legitimate pollinator of *Tristerix* mistletoe in Peru.
Breeding. Fledglings reported in Dec–Jun and juveniles and immatures throughout year in Peru. No other information.
Movements. Probably chiefly resident. Little precise information. Local movements in response to changing nectar abundance may occur; in W Peru reported as shifting habitats seasonally, but no quantitative details.
Status and Conservation. Not globally threatened. Nominate race common and widespread, especially in dry intermontane valleys in Peru; occurs in Manu National Park and probably Huascarán National Park, both in Peru. Status of Colombian race *vuilleumieri* unclear. The species' range also includes large areas of disturbed vegetation which is not protected, but which provides suitable habitat for this species.
Bibliography. Athanas (2010a, 2010b), Clements & Shany (2001), Fjeldså & Krabbe (1990), Graves (1980, 1982a, 1982b, 1991), Hellmayr (1935), Hilty & Brown (1986), Isler & Isler (1999), Jaramillo (2003), Koepcke (1970), Mauck & Burns (2009), Mayer (2000), McCarthy (2006), Meyer de Schauensee (1970a), Moynihan (1979), Phelps & Phelps (1950), Remsen *et al.* (2010), Restall *et al.* (2006), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schulenberg *et al.* (2007), Taczanowski (1884), Vuilleumier (1969b, 1984a), Walker (2001).



201. **Grey-bellied Flowerpiercer**

Diglossa carbonaria

French: Percefleur charbonnier **Spanish**: Pinchaflor Carbonero
German: Grauschulter-Hakenschnabel
Other common names: Grey-bellied Flowerpecker, Coal-black/Carbonated Flowerpiercer/Flowerpecker

Taxonomy. *Serrirostrum carbonaria* d'Orbigny and Lafresnaye, 1838, Sicasica, La Paz, Bolivia. Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Present species forms a monophyletic group with *D. gloriosa*, *D. humeralis* and *D. brunneiventris*, and all were previously regarded as conspecific; known to hybridize, to limited extent, with *D. brunneiventris* in small area of range overlap in Bolivia (La Paz). Monotypic.

Distribution. Bolivia from vicinity of La Paz (city of La Paz) SW along E ridge of Andes to departments of Santa Cruz and Chuquisaca, and N Argentina (N Jujuy).

Descriptive notes. 13 cm; 9–14·8 g. Medium-sized flowerpiercer with grey, black and rufous plumage, slender and somewhat upturned bill with prominent hook at tip. Has head, throat and most of upperparts black, dark grey rump contrasting only slightly with rest of upperparts (and often hidden); marginal and lesser upperwing-coverts light grey (forming small triangular patch on shoulder), variable number of scapulars sometimes pale grey, rest of upperwing black, tail black; breast, belly, sides and flanks grey, upper breast somewhat mottled and streaked with black, undertail-coverts rufous; throughout range, a few individuals have some plumage characteristics typical of *D. brunneiventris*, including rufous malar and rufous feathers on underparts; iris dark brown; bill black, basal half of lower mandible pale grey; legs dusky grey. Sexes similar. Juvenile is somewhat streaked, upperparts dark greyish-brown, underparts similar but paler and with obscure dusky to buff streaking, sides greyish-brown and somewhat streaked brown, belly buff, undertail-coverts dull rufous; immature dark brown above with hint of dark olive streaking, two faint wingbars, edges of inner flight-feathers and tertials buffy brown, grey below, becoming buff on belly, most of underside from throat to belly variably streaked dusky, overall much like immature of *D. brunneiventris*. VOICE. Song a rapid, complex jumble of high-pitched notes somewhat like song of *D. brunneiventris*, lasts c. 3 seconds and repeated every few seconds during peak bouts, e.g. "peeza-peeza-seetza'sizza-peeza'teez-teez'za-te-za-te-t-t", trailing off and ending inconclusively in a series of perceptibly slower, single notes.

Habitat. Dry montane scrub, patches of scrubby woodland at tree-line, and settled areas with hedgerows, gardens and brush; less often in light woodland in semi-humid and humid regions. At 2100–4300 m.

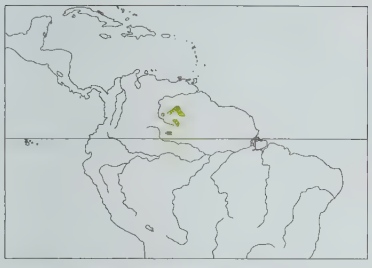
Food and Feeding. Nectar, also insects. Stomach contents largely insects. Occurs in pairs when breeding, mainly singly at other times. Territorial and aggressive in defending small patches of flowers. Highly active and nervous in behaviour, and may remain largely hidden, or appear only momentarily, as it works quickly through denser vegetation. Also takes many insects from foliage and in short aerial sallies. Behaviour generally similar to that of *D. brunneiventris*.

Breeding. Fledglings seen in Dec–Jul and juveniles and immatures in Mar–Jul and Dec. No other information.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Bolivian and Peruvian Upper Yungas EBA and High Andes of Bolivia and Argentina EBA. Generally common within limited range. Recent sight record of this species from extreme NW Argentina (near Jujuy) requires corroboration. Occurs in a few protected areas, including Tunari National Park and probably also in Madidi, Carrasco and Amboró National Parks. Within its range extensive habitat alteration has resulted from firewood-cutting, burning, grazing and agriculture, but the species adapts well to these altered environments and is unlikely to face any serious threats in the short term.

Bibliography. Cahill (2008), Fjeldså & Krabbe (1990), Graves (1980, 1982a, 1982b, 1991), Hellmayr (1935), Isler & Isler (1999), Kessler & Herzog (1998), Mayer (2000), McCarthy (2006), Meyer de Schauensee (1970a), Moynihan (1979), Phelps & Phelps (1950), Remsen *et al.* (2010), Ridgely & Tudor (1989, 2009), Sclater (1875), Vuilleumier (1969b, 1984a), Vuilleumier & Ewert (1978).



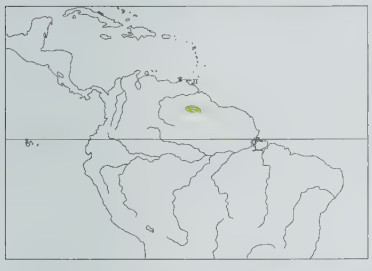
202. **Scaled Flowerpiercer**

Diglossa duidae

French: Percefleur des tépuis **Spanish**: Pinchaflor del Duida
German: Schuppenbrust-Hakenschnabel
Other common names: Scaled Flowerpecker

Taxonomy. *Diglossa duidae* Chapman, 1929, Mount Duida, 6600 feet [c.2010 m], Amazonas, Venezuela. Genus has sometimes been placed in Coerèbidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Race *georgebarrowcloughi* differs little from *hitchcocki* and perhaps better subsumed within latter; retained pending further study. Proposed race *parui* (described from Cerro Parú, in NC Amazonas) considered inseparable from nominate. Three subspecies currently recognized.

Subspecies and Distribution.
D. d. duidae Chapman, 1929 – isolated tepuis in Amazonas (including Cerro Parú, Cerro Huachamacari, Mt Duida and Cerro Marahuaca) and SW Bolívar (Meseta de Jaua and Cerro Sarisariñama), in S Venezuela.
D. d. hitchcocki Phelps, Sr & Phelps, Jr, 1948 – Cerro Sipapo, Cerro Guanay and Cerro Yavi (N Amazonas), in S Venezuela.
D. d. georgebarrowcloughi Dickerman, 1987 – Cerro de la Neblina, on S Venezuela–Brazil border.
Descriptive notes. 14 cm; male 11·9–18·5 g, female 12·9–16 g. All-dark flowerpiercer with upturned bill strongly hooked at tip of upper mandible. Nominate race is slaty black above, head darker, marginal and lesser upperwing-coverts broadly tipped paler blue-grey (forming small, inconspicuous, paler triangular shoulder patch), similar tips less developed on median coverts, greater coverts sometimes faintly tipped whitish (hint of pale wingbar), flight-feathers and tail dusky, with narrow slate-grey fringes; throat and chest slate-grey, gradually becoming slightly paler on lower underparts, feathers of lower breast and belly with pale grey subterminal crescents (imparting somewhat scaled appearance), undertail-coverts mixed grey and whitish; iris reddish-brown; bill black, basal portion of lower mandible greyish-horn; legs dusky grey. Sexes similar. Juvenile has crown blackish, upperparts and throat dull dusky grey (no bluish), median and greater upperwing-coverts



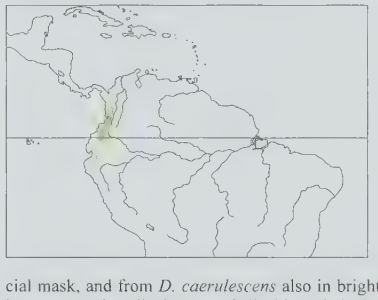
tipped whitish (forming fairly well-defined pale wingbars), breast and lower underparts medium grey, somewhat spotted with white; immature like juvenile, but darker above, whitish wingbar (usually only one) less distinct, and underparts darker and much like those of adult. Race *hitchcocki* is very like nominate, but glossier above, spots and scales of underparts visible from foreneck downwards, those of lower underparts slightly larger and brownish, and undertail-coverts scaled with white; *georgebarrowcloughi* is quite similar to nominate, but slightly larger, blacker with slight bluish gloss above, black of underparts more confined to throat, and more obviously scaled and spotted below. Voice. No information.
Habitat. Poorly known. Probably scrubby humid forest on rocky slopes and tops of tepuis, but habitat not well documented. Recorded at 1400–2600 m; lower-elevation records from Cerro Sipapo (1400–1800 m), highest ones from Cerro Marahuaca and Cerro de la Neblina.
Food and Feeding. No information. Presumably much as for *D. major*.
Breeding. No information.
Movements. Presumably resident.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Very poorly known. Probably common, as numerous specimens have been collected, from a number of different sites. Occurs on many tepuis in S Venezuela, almost all of which are remote and of difficult access, and have been visited only rarely by scientific expeditions. This species is perhaps the most poorly known of its genus, essentially unknown in life, and with no certain information on its status or any aspects of its natural history. Except for scattered Amerindian villages at bases of some tepuis, there is almost no human activity within the distributional range of this species, and no human intervention on the upper slopes where it lives. It is, thus, one of the few members of its genus which has had no exposure to human activity or habitat alteration, and it is unlikely that it will face any threats in the foreseeable future.
Bibliography. Dickerman (1987), Hilty (2003), Isler & Isler (1999), Mauck & Burns (2009), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1950), Restall *et al.* (2006), Ridgely & Tudor (1989, 2009), Souza (2002).

203. Greater Flowerpiercer

Diglossa major

French: Grand Percefleur **German**: Strichelhakenschnabel **Spanish**: Pinchaflor Grande
Other common names: Greater Flowerpecker, Great Flowerpiercer

Taxonomy. *D[iglossa] major* Cabanis, 1848, Cerro Roraima, 6000 feet [c. 1830 m], near border of Guyana and Venezuela.
Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. Four subspecies recognized.
Subspecies and Distribution.
D. m. gilliardi Chapman, 1939 – Auyán-tepui (SE Bolívar), in SE Venezuela.
D. m. disjuncta J. T. Zimmer & Phelps, Sr, 1944 – tepuis on W side of Gran Sabana (including Ptaritepui, Sororopán-tepui, Uaipán-tepui, Aprada-tepui, and Acopán-tepui), in SE Venezuela.
D. m. chimantae Phelps, Sr & Phelps, Jr, 1947 – Chimantá-tepui (SE Bolívar).
D. m. major Cabanis, 1848 – Cerro Roraima, including sites within Venezuela, Brazil and Guyana; also Cerro Cuquenán and Uei-tepui, in extreme SE Bolívar (Venezuela).
Also on Sierra de Lema (E Bolívar), race uncertain, presumably referable to nominate.



Descriptive notes. 17·3 cm; 17·5–25 g (*disjuncta*). The largest flowerpiercer, dark and rather long-tailed, with bill noticeably thick at base and strongly hooked. Nominate race has forehead, lores, periocular area and chin black (forming mask), fading to bluish-slate across ear-coverts, moustachial region spotted bluish-white (narrow moustachial stripe); otherwise slightly glossed bluish-slate above, rear crown to uppertail-coverts with inconspicuous silvery-blue shaft streaks; lesser and median upperwing-coverts dark bluish like body, and with a few pale shaft streaks, greater coverts and primary coverts dull black; flight-feathers and tail blackish, narrowly and obscurely edged whitish; throat and underparts paler slaty grey (minimal bluish tinge) with just a few indistinct pale shaft streaks, undertail-coverts ochre-rufous; iris brown to deep red-brown; bill pale blue-grey, blackish on culmen and tip; legs dusky black. Sexes similar. Immature is dusky brown above, grey-brown with dull whitish streaking below, white moustachial stripe freckled black, undertail-coverts chestnut. Race *gilliardi* is much like nominate, but darker, slightly glossed, with ear-coverts more extensively black, moustachial stripe only weakly defined, flight-feathers edged pale blue (not whitish), and underparts more slaty bluish (less grey) and with more obviously pale blue shaft streaks; *disjuncta* is similar to previous, but streaking obscure or largely lacking, underparts less blue, vent and undertail-coverts deep chestnut; *chimantae* only slightly darker than nominate, underparts plain slate-grey, vent and undertail-coverts deep chestnut. Voice. Unusual song, typically delivered from prominent high perch by single individual, or in complex duet, consists of rapid burst of high-pitched and variable notes more or less repeated over and over for 20–30 seconds, occasionally up to several minutes; in duets, one bird sings a series of harsh or flat, low-pitched notes, the other a repetition of high-pitched, tinkling notes all of which rise and fall in pitch and may vary also in volume. Song, whether delivered singly or as duet, is chattery, rather than musical, and like pulses or bursts of scratchy static that swell and then fade in volume as the bird turns its head.
Habitat. Borders and middle and upper levels of humid and wet montane forest, stunted cloudforest, dense, mossy second growth, and especially borders of melastome-dominated second growth on white sandy soil. At 1400–2850 m in Venezuela, but numerous only at high elevations, e.g. common to abundant above c. 2000 m on Cerro Roraima; elsewhere mainly above 1800 m, once as low as 1200 m on Guyana side of Cerro Roraima. On Sierra de Lema, highest elevations little more than 1500 m.
Food and Feeding. Nectar, also insects. Occurs singly, in pairs when breeding, and is usually independent of mixed-species flocks. Forages from eye level up to canopy, more often high. Active; frequently wing-flicks as it moves restlessly through foliage. Pierces bases of flower corollas, also probes directly into short flower corollas for nectar (and presumably insects); especially attracted to flowers of arboreal bromeliads.
Breeding. Nests attributed to this species described as open cup of grass and small sticks situated among rocks, usually under overhanging shelf and less than 0·4 m up; further verification desirable, as other members of genus typically build nests of moss, ferns and tiny rootlets. No other information.
Movements. Few data; altitudinal movement noted. Marked seasonal movements at lower elevations (i.e. on Sierra de Lema), but little information from higher elevations, where the species is much more numerous.
Status and Conservation. Not globally threatened. Restricted-range species: present in Tepuis EBA. Rare (at low elevations) to abundant (higher elevations). Common to abundant above c. 2000 m on Cerro Roraima; scarce and local on Sierra de Lema (one of the few accessible localities where the species is recorded), which rises to little more than 1500 m. Occurs in Canaima National Park (Venezuela) and Kaieteur National Park (Guyana). Although total range occupied by this species is small, it faces no real threats. Distribution is naturally fragmented, with various populations largely or entirely isolated from each other at present time. Few human settlements exist within its range. Unregulated mining for gold and diamonds, burning of grassland, road-building projects and long-distance power transmission lines are ongoing activities in the region, although few of these, at present, directly affect this species.
Bibliography. Braun *et al.* (2003), Chapman (1939), Gilliard (1941), Hilty (2003), Isler & Isler (1999), Lovette & Bermingham (2002), Mauck & Burns (2009), Meyer de Schauensee & Phelps (1978), Phelps (1938), Phelps & Phelps (1950), Restall *et al.* (2006), Ridgely & Tudor (1989, 2009), Souza (2002).

204. Indigo Flowerpiercer

Diglossa indigotica

French: Percefleur indigo **German**: Indigohakenschnabel **Spanish**: Pinchaflor Índigo
Other common names: Indigo Flowerpecker

Taxonomy. *Diglossa indigotica* P. L. Sclater, 1856, Ecuador.
Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. This species, along with *D. glauca*, *D. caerulescens* and *D. cyanea*, has sometimes been placed in separate genus, *Diglossopis*, on grounds of some important anatomical features (of corneous tongue, bony palate, maxillo-palatines and mandible, and structure of rhamphotheca), all of which may set them apart from present genus; these four species, with a proportionately smaller bill hook, may have evolved only once, while all other flowerpiercers (with larger hook) may have evolved multiple times; recent molecular-genetic data, however, indicate that these four "small-billed" species do not form a monophyletic group, and all flowerpiercers are best retained in a single genus. Monotypic.
Distribution. Pacific slope of W Andes from Risaralda (Cerro Tatamá), in Colombia, S to NW Ecuador (Pichincha).

Descriptive notes. 11 cm; 10·5–18 g. Very small, rather short-tailed, dark flowerpiercer with short bill upturned (especially lower mandible), upper mandible hooked at tip. Has lores, narrow ocular area and chin black, otherwise bright shining indigo-blue above and below; tail dusky, feathers edged bright blue; lesser upperwing-coverts indigo-blue, median and greater coverts dusky, heavily edged indigo-blue, flight-feathers blackish, narrowly edged bright blue, tertials more broadly edged turquoise-blue; iris fire-red; bill and legs black. Differs from similar *D. cyanea* in smaller size, shorter bill and lack of obvious dark facial mask, and from *D. caerulescens* also in brighter blue coloration. Sexes similar. Juvenile and immature undescribed. Voice. Call a high-pitched, thin note reminiscent of that of *D. caerulescens*. Unusual song (markedly dissimilar to those of congeners) a series of extremely high-pitched, penetrating and evenly spaced notes that gradually descend, e.g. "see'see'see'ee'ee'ee'ee'ti'ti'ti'ti 'ti'ti'ti' ti'te'te'te'ee'ee'ee'ee'eee, eee," c. 20–30 or more notes in 4·5–6·5 seconds, the notes with pulsating quality. Context of a thin, almost strained "squik, squik, squik, squik", at deliberate pace, is unknown.
Habitat. Humid and wet montane forest, especially moss-clad and bromeliad-laden cloudforest and along wet and mossy forest borders and tall second growth. At 700–2200 m in Colombia; the few records in Ecuador mostly at 1600–2000 m. Generally at lower elevations than most other members of genus within its range.
Food and Feeding. Nectar, berries and small arthropods. Occurs singly or in pairs, and persistently with mixed-species flocks containing *Tangara* and *Chlorochrysa* tanagers. Hyperactive, constantly fidgeting, wing-flicking and flitting along mossy branches and among tangles of vines, bromeliads and other epiphytes. Behaviour recalls that of a parulid warbler (e.g. *Dendroica*) more than a flowerpiercer. Has been observed to puncture small tubular flower corollas for nectar, but more often seen as it peers and gleans for small arthropod prey and berries on branches covered with epiphytes and moss.
Breeding. One bird carrying nesting material in Jun in Colombia (Valle). No other information.
Movements. No information. Some local movements possible; during intensive 15-month study in Anchicayá Valley (1050 m) in W Colombia, the species was observed in all months except Apr and Jul, but appeared to be much more numerous in some months than in others.
Status and Conservation. Not globally threatened. Restricted-range species: present in Chocó EBA. Fairly common very locally in Colombia; rare and local in Ecuador, with few verified records anywhere within presumed range in that country (old records from Nanegel and Canzacoto, in

On following pages: 205. Deep-blue Flowerpiercer (*Diglossa glauca*); 206. Bluish Flowerpiercer (*Diglossa caerulescens*); 207. Masked Flowerpiercer (*Diglossa cyanea*).

Pichincha, and one uncorroborated sight record in El Oro). Occurs in Farallones de Cali and Munchique National Parks, the protected watershed of upper R Anchicayá hydropower dam, Tambito Nature Reserve and probably also Tatamá National Park (Colombia); may occur also in one or more private reserves in extreme SW Colombia, e.g. Pangan Reserve and Río Nambí Community Nature Reserve. Much of the species' small range is rapidly being deforested or damaged through a combination of agriculture, mining, logging and increased human settlement. Reasons for its extreme scarcity in Ecuador, despite some apparently suitable habitat, are unknown. Should perhaps be listed as Near-threatened or even Vulnerable.

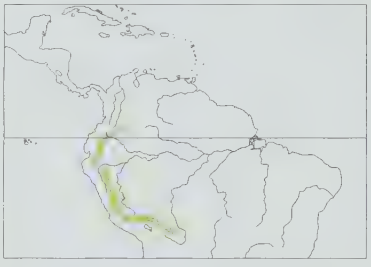
205. **Deep-blue Flowerpiercer**

Diglossa glauca

French: Percefleur glauque **German**: Ultramarin-Hakenschnabel **Spanish**: Pinchaflor Glauco
Other common names: Deep-blue Flowerpecker, Golden-eyed Flowerpiercer



Taxonomy. *Diglossa glauca* P. L. Sclater and Salvin, 1876, Nairapi, Bolivia.

Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. This species, along with *D. indogotica*, *D. caerulescens* and *D. cyanea*, has sometimes been placed in separate genus, *Diglossopis*, on grounds of some important anatomical features (of corneous tongue, bony palate, maxillo-palatines and mandible, and structure of rhamphotheca), all of which may set them apart from present genus; these four species, with a proportionately smaller bill hook, may have evolved only once, while all other flowerpiercers (with larger hook) may have evolved multiple times; recent molecular-genetic data, however, indicate that these four "small-billed" species do not form a monophyletic group, and all flowerpiercers are best retained in a single genus. Geographical variation of present species minimal, race *tyrianthina* differing only slightly from nominate; species perhaps better treated as monotypic. Two subspecies currently recognized.

Subspecies and Distribution.

D. g. tyrianthina Hellmayr, 1930 – S Colombia on E slope of E Andes (in W Caquetá, W Putumayo and E Nariño) and S on adjacent E slope in Ecuador to about Peru border and to extreme N Peru (Cordillera del Condor).

D. g. glauca P. L. Sclater & Salvin, 1876 – E slope in N Peru (S of R Marañón) S to Bolivia (to Cochabamba).

Descriptive notes. 11–12 cm; 9·5–13 g. Small golden-eyed flowerpiercer with short and somewhat upturned bill with prominent hook at tip of upper mandible. Male nominate race is mainly deep blue throughout, with very narrow black area on forehead, lores and chin; upperwing-coverts, flight-feathers and tail dusky, edged deep blue; iris brilliant golden-yellow; bill black; legs dusky. Female is similar to male, but slightly duller. Juvenile and immature undescribed. Race *tyrianthina* is very like nominate, but black more restricted to loral area. Voice. When foraging often gives high-pitched pure "keeeee", mechanical or amphibian-like, sometimes doubled, also "ti-ti-dweeeer", and sharp "psew". Song in Colombia described as high thin series of chips and squeaks, dropping, accelerating and very jumbled at end; in Peru as variable, very high and wheedling, with melancholy quality, less musical than songs of *D. cyanea*, more varied than song of *D. caerulescens*; may give a flat trill (much like that of *D. albilatera*). These descriptions, however, do not agree with several recent recordings of song made in Ecuador and Peru, which similar to song of *D. indigotica* but shorter, weaker and less penetrating, e.g. very high-pitched thin series of "ti" notes at moderate pace and descending slightly, "ti-ti-ti-ti-ti-ti-te-te-te-te". Possible that more than one song type is given. Call note a thin high "ti", often a few given as lead-in to last-mentioned song.

Habitat. Humid to wet, mossy forest (cloudforest) and along wet forest borders. At 1400–2300 m in Colombia, mainly 1000–1800 m in Ecuador, and 1000–2300 m in Peru; generally at lower elevations than most congeners within its range.

Food and Feeding. Diet little known; insects and berries, possibly also nectar. Single birds or pairs are persistent members of mixed-species flocks, especially those containing *Tangara* tanagers. Forages mainly for insects, especially in bromeliads and on mossy branches; often takes small berries. Although hooked bill is suitable for piercing flowers, this species, like *D. indigotica*, is not often seen at flowers.

Breeding. No information.

Movements. No relevant information.

Status and Conservation. Not globally threatened. Locally fairly common. Occupies a narrow band of cloudforest on E slope of Andes that is at risk from deforestation, settlement and other human activities. Occurs, or probably occurs, in a number of protected areas on E Andean slope, among them Cayambe-Coca and Antisana Ecological Reserves and Sangay and Podocarpus National Parks (Ecuador), Cordillera Azul, Tingo Maria and Manu National Parks (Peru) and probably Madidi National Park (Bolivia).

Bibliography. 206. **Bluish Flowerpiercer**

Diglossa caerulescens

French: Percefleur bleuté **German**: Silberhakenschnabel **Spanish**: Pinchaflor Azulado
Other common names: Bluish Flowerpecker

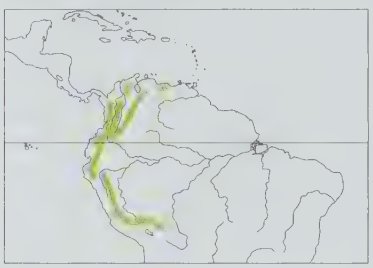
Taxonomy. *Diglossopis caerulescens* P. L. Sclater, 1856, Caracas, Venezuela.

Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. This species, along with *D. indogotica*, *D. glauca* and *D. cyanea*, has sometimes been placed in separate genus, *Diglossopis*, on grounds of some important anatomical features (of corneous tongue, bony palate, maxillo-palatines and mandible, and structure of rhamphotheca), all of which may set them apart from present genus; these four species, with a proportionately smaller bill hook, may have evolved only once, while all other flowerpiercers (with larger hook) may have evolved multiple times; recent molecular-genetic data, however, indicate that these four "small-billed" species do not form a monophyletic group, and all flowerpiercers are best retained in a single genus. Some races of present species weakly differentiated; *intermedia* differs only slightly from *saturata* (to N of it) and *pallida* (to S), being intermediate between the two, and may not merit recognition. A slightly paler specimen of *saturata* from El Chaco, on E slope in Ecuador, is perhaps intermediate between that race and *media*. Some authors have suggested that all specimens from C & W Andes of Colombia and adjacent NW Ecuador (currently placed in *saturata*) belong to an as yet unnamed race, and that specimens from most of Ecuadorian range of *media* (except SW Ecuador) represent an additional undescribed race; further study required. Seven subspecies tentatively recognized.

Subspecies and Distribution.

D. c. ginesi Phelps, Sr & Phelps, Jr, 1952 – upper R Negro region of Sierra de Perijá, in W Venezuela.

D. c. caerulescens (P. L. Sclater, 1856) – coastal cordillera of N Venezuela (Carabobo, Aragua, Vargas and Distrito Federal).



D. c. saturata (Todd, 1917) – Andes of Venezuela (from Trujillo S to Táchira), and all three ranges in Colombia and apparently Andes of N Ecuador (S to Pichincha on W slope; a specimen from El Chaco on E slope).

D. c. media J. Bond, 1955 – N portion of E slope of Andes in Ecuador (specimen from at least as far N as Sierra Azul, in Napo) S to E slope in N Peru (Cajamarca and N Amazonas).

D. c. intermedia Carriker, 1935 – Department of Cajamarca (Chira, Tambillo, Palto, Tabaconas, Levanto and Tamiapampa), in N Peru.

D. c. pallida (Berlepsch & Stolzmann, 1896) – N & C Peru (from S side of R Marañón S to La Libertad, Lima and Junín).

D. c. mentalis J. T. Zimmer, 1942 – E slope of Andes in S Peru S to Bolivia (La Paz).

Descriptive notes. 13·5 cm; 10·1–16 g. Relatively dull, bluish flowerpiercer with rather long and thin bill only slightly upturned and with proportionately smaller hook at tip than in any other member of genus. Male nominate race is mainly dull bluish-grey, with lowermost forehead, loral area and small area around eye blackish (forming small, rather weakly defined mask); upperwing-coverts dull blue, primary coverts and flight-feathers dusky, edged blue; throat and underparts slightly paler than upperparts, dull blue somewhat mixed with whitish feather edging, greyer on centre of belly; iris dark red to orange-red, red colour often inconspicuous; bill black; legs dark grey. Female is similar to male, but duller, with duller eyes. Juvenile is duller still, with faint streaking on lower parts, base of lower mandible yellow; immature resembles adult, but duller blue, mask obscure, and eyes brownish to reddish-brown. Races vary most obviously in tone of blue, also in size, nominate largest: *ginesi* differs from nominate in slightly paler and duller upperparts, smaller mask; *saturata* is decidedly darker and slightly more purplish above, and darker, more slaty blue, below; *media* is much like nominate (and previous), but slightly brighter blue above and not so purplish-tinged below, and has more whitish edging on lower underparts; *intermedia* is clearer and bluer above, close to *saturata*, with underparts almost exactly intermediate between latter and *pallida*, showing definite contrast between breast and belly, and with breast paler than that of *saturata*; *pallida* is dullest race, essentially grey below, with throat and upper breast only slightly darker (weak demarcation) than lower underparts; *mentalis* is darker than last, has upperparts with clearer bluish tinge, throat and breast darker greyish, point of chin with small blackish area spreading over anterior malar region. Voice. In Peru, song described as a variable, high, lisping, melancholy warble, descending in pitch; in Venezuela and Colombia a few slow, high notes, then an accelerating shower of chattery staccato notes (may vary geographically or possibly individually) that cascade from tree canopy, e.g. "eeeéét, esa-eet, eat-tsu-ti' tip-ta-leep' ta-lip, chlip, chee-ep, cheelip' iz si..." and so on, often descending somewhat in pitch and ending in fussy, tittering jumble varying from 2 seconds to long-sustained. Context of song variation unknown. In Venezuela and Colombia, often heard call a hard, metallic, "tiink", distinctive once learned.

Habitat. Humid montane forest, older second growth and forest borders; in S part of range (Peru) may favour scrubbier forest on nutrient-poor soils. At 1400–2100 m in N Venezuela, c. 1600–3200 m S in Andes (mainly 2100–2700 m in Colombia and Ecuador, although has been reported much lower and higher), 1300–3100 m in Peru.

Food and Feeding. Insects, also small berries (especially *Miconia*), and reported taking fruits of *Cavendishia bracteata* in Colombia and of *Rubus* in several places; also takes nectar. Forages singly and in pairs; most often seen when accompanying mixed-species flocks containing New World warblers (Parulidae), other flowerpiercers and other tanagers. Forages in middle levels and canopy of forest, where it feeds extensively on small berries and gleans insects from outer foliage and twigs. Infrequently punctures flowers for nectar (far less than do many smaller species) and, when taking nectar, most often probes flowers directly. Behaviour and feeding more like those of *D. cyanea* and of various parulid warblers and *Tangara* tanagers than those of other flowerpiercers; not so active and nervous as its smaller congeners, nor is it so furtive.

Breeding. Nest with eggs in Feb in Venezuela (Trujillo), juvenile/immature in Dec (Santander) and eight birds in breeding condition in Jun–Aug in Colombia, and fledgling reported in Feb in N (Amazonas) and juvenile/immature in Jun (N) and Aug (in S) in Peru; these records, collectively, suggest breeding from mid-dry season through first part of rainy season. Nest an open cup of dry grass and moss, placed in bush, Venezuela nest sited in deep pocket on steep mossy roadbank. No information on clutch size, nest in Venezuela held 2 eggs, eggs in Colombia pale greenish-blue, blotched and spotted reddish-brown, mainly at large end. No other information.

Movements. Mainly resident. Seasonal movements reported (without details) in N Venezuela; occasional records elsewhere at higher or lower elevations suggest limited seasonal movements, but documentation needed.

Status and Conservation. Not globally threatened. Common and relatively widespread; scarce or absent locally, e.g. in NW Ecuador. Occurs in numerous protected areas, including Henri Pittier and Sierra Nevada National Parks (Venezuela), Chingaza and Los Farallones National Parks and

Reinita Cielo Azul, Tambito and Río Blanco de Manizales Nature Reserves (Colombia), Manu National Park (Peru), and presumably other reserves on E slope in Ecuador, Peru and Bolivia. This species is often fairly numerous in older regrowth forest where there are fruiting trees (e.g. melastomes) with small berries, a habitat that should to some extent act as a buffer against risk.

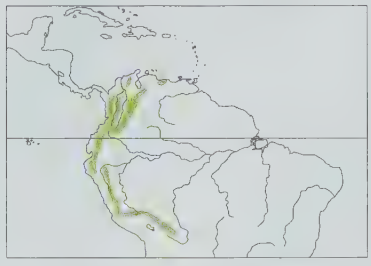
207. **Masked Flowerpiercer**

Diglossa cyanea

French: Percefleur masqué **German**: Maskenhakenschnabel **Spanish**: Pinchaflor Enmascarado
Other common names: Masked Flowerpecker



Taxonomy. *Uncirostrum cyaneum* Lafresnaye, 1840, Santa Fé de Bogotá, Colombia.

Genus has sometimes been placed in Coerebidae or Parulidae or even, because of an apparent close relationship to *Acanthidops*, in Emberizidae. Molecular phylogenies indicate that it is most closely related to *Xenodacnis* and to *Acanthidops*, *Haplospiza* and *Catamenia* (the last three genera currently placed in Emberizidae), and that all clearly belong in present family. Members of this clade may also be closely related to the *Oreomanes–Conirostrum* clade. This species, along with *D. indogotica*, *D. glauca* and *D. caerulescens*, has sometimes been placed in separate genus, *Diglossopis*, on grounds of some important anatomical features (of corneous tongue, bony palate, maxillo-palatines and mandible, and structure of rhamphotheca), all of which may set them apart from present genus; these four species, with a proportionately smaller bill hook, may have evolved only once, while all other flowerpiercers (with larger hook) may have evolved multiple times; recent molecular-genetic data, however, indicate that these four "small-billed" species do not form a monophyletic group, and all flowerpiercers are best retained in a single genus. Distributional limits of race *obscura* of present species uncertain; not yet recorded on Colombian side of Perijá Mts, but may extend S to meet nominate race near border of Venezuela with Colombia. Five subspecies recognized.

Subspecies and Distribution.

D. c. obscura Phelps, Sr & Phelps, Jr, 1952 – Sierra de Perijá, in W Venezuela.
D. c. tovarensis J. T. Zimmer & Phelps, Sr, 1952 – coastal cordillera of N Venezuela (in Aragua and Distrito Federal).
D. c. cyanea (Lafresnaye, 1840) – Andes of Venezuela (S from Trujillo) and all three ranges in Colombia and Andes of Ecuador (except far SW).
D. c. dispar J. T. Zimmer, 1942 – Andes of SW Ecuador and NW Peru.
D. c. melanopis Tschudi, 1844 – Andes of Peru (except NW) S to Andes in Bolivia (to Santa Cruz).

Descriptive notes. 15 cm; 12–22·5 g. Large, rich blue flowerpiercer with red eyes and large black mask, rather long and thin bill only slightly upturned and with relatively small hook at tip of upper mandible. Nominate race is rich, shining dark blue, with conspicuous black mask across forehead and extending back around and below eye to ear-coverts and forwards to chin; lesser upperwing-coverts blue (generally hidden), rest of wing-coverts, flight-feathers, tertials and tail black, broadly edged dark blue; iris bright red; bill black; legs dusky. Female is similar to male, but slightly duller. Juvenile and immature are much duller and greyish, especially below, where almost entirely dull dark grey, black mask faintly indicated, with iris dark, base of bill pale; subadult has dark red iris. Races differ mainly in intensity of blue colour: *obscura* differs from nominate in overall darker blue

colour; *tovarensis* is rather like nominate, but brighter and paler blue, especially on forecrown, with black mask more contrasting; *dispar* differs from nominate in that blue colour has more of a greenish tinge (less violaceous tinge); *melanops* is slightly larger than others, and generally darker and duller than nominate, with blue of outer margins of tertials less sharply outlined. VOICE. In N Venezuela, song (race *tovarensis*) given all year, a high, wiry series of 2–3 thin "zeet" notes, then a rapid, increasingly complex series of tinkling and twittering notes, descending somewhat in pitch and often ending in 2 thin but distinct "zeet" or "seet" notes; each bird may sing slightly different song, or several different songs, but the 2–3 introductory notes distinctive and constant (and seem to be lacking in other members of genus in Venezuela). In S songs seem less distinctive, in Ecuador described as a series of thin notes followed by a twitter, and in Peru as a variable high, lisping, melancholy warble, more melodic than song of *D. caerulescens*. Song variation seems sufficiently marked to warrant further study. Sings from partly concealed perch near top of bush or tree, perhaps less often from exposed perch.

Habitat. Humid montane forest (cloudforest) and forest borders and in smaller numbers to tree-line, where occurs in elfin forest and low shrubs. Recorded at 1450–3600 m, mainly c. 1800–3300 m.

Food and Feeding. Small fruits and berries (especially species of Melastomataceae), also some insects; more frugivorous than any other member of genus. Seen singly, in pairs, and regularly also in varyingly sized flocks of its own, and in all cases often accompanies mixed-species flocks in forest canopy or middle level or along edges of forest. Most often seen as it moves quickly along mossy branches, twigs, vines and in foliage, where it searches for small food items. Has been seen to pierce small fruits for juice, and frequently makes short sallies to air for flying insects. Only rarely punctures or visits flowers, then usually probing them directly.

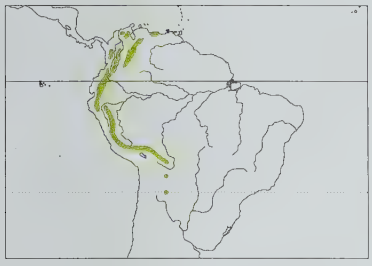
Breeding. Fledglings in Dec, Mar and Apr in Venezuela and Colombia and in Mar, May, Jul and Dec in Peru and Bolivia, immatures reported virtually throughout year, and nine birds in breeding condition Jun–Sept in Colombia; may breed twice each year, even while in moult, in Venezuela and Colombia. Open cup-nest of moss, grass and feathers, generally placed in bush; nest and eggs from Antioquia (Colombia) much like those of *D. caerulescens*, but nest feather-lined, and eggs slightly larger. No other information.

Movements. Poorly documented. In some areas undertakes seasonal or periodic movements, mostly between higher and lower elevations; at such times single-species groups of 20–30 individuals may move together, e.g. c. 25 birds seen while streaming upslope (moving upwards from c. 1450 m) in state of Barinas, Venezuela, in Jun (early rainy season); similar groups reported farther S in Andes.

Status and Conservation. Not globally threatened. Fairly common to common; widespread. Occurs in many parks and reserves, among them Henri Pittier, Sierra Nevada and Tamá National Parks (Venezuela), Chingaza, Las Orquídeas, El Cocuy, Los Nevados, Nevado del Huila, Cueva de los Guácharos and Puracé National Parks (Colombia), Sangay and Podocarpus National Parks (Ecuador), Cordillera de Colán, Tingo María and Manu National Parks (Peru) and Madidi National Park (Bolivia). This species also occurs in many unprotected areas of montane forest, some of which are at risk, others at little risk in immediate term.

Bibliography. Anon. (2000), Bardeleben & Gray (2005), Bock (1985), Donegan & Dávalos (1999), Fjeldså & Krabbe (1990), Hellmayr (1935), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Koenen & Koenen (2000), Krabbe *et al.* (2001), Mauck & Burns (2009), Moore *et al.* (1999), Remsen, Cadena *et al.* (2010), Remsen, Traylor & Parkes (1987), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman, Donegan & Caro (2008), Salaman, Donegan & Cuervo (1999), Schulenberg (2000b), Schulenberg *et al.* (2007), Sclater & Salvin (1879), Sibley & Monroe (1990), Vuilleumier (1969), Walker (2001).

Genus *CATAMBLYRHYNCHUS* Lafresnaye, 1842



208. **Plushcap**

Catamblyrhynchus diadema

French: Tête-de-peluche couronné **German**: Plüschkopftangare **Spanish**: Tangara Peluda
Other common names: Plush-capped Finch

Taxonomy. *Catamblyrhynchus diadema* Lafresnaye, 1842, "Bogotá".
Relationships uncertain. Genus has been placed variously in a separate monotypic family, Catamblyrhynchidae, and in a separate subfamily, Catamblyrhynchinae, within Emberizidae; molecular-genetic data support its inclusion in present family. Three subspecies recognized.

Subspecies and Distribution.
C. d. diadema Lafresnaye, 1842 – W Venezuela (Sierra de Perijá, and Andes S from Trujillo) and Colombia (Santa Marta Mts, and Andes generally) S to S Ecuador.
C. d. federalis Phelps, Sr & Phelps, Jr, 1953 – coastal cordillera (Aragua, Vargas and Distrito Federal, probably also Miranda), in N Venezuela.
C. d. citrinifrons Berlepsch & Stolzmann, 1896 – Andes of Peru S on W slope to Lambayeque, and throughout E slope S to Bolivia (La Paz, Cochabamba and W Santa Cruz) and to NW Argentina (Jujuy).
Descriptive notes. 14 cm; 16 g, male average 14·9 g and female average 13·4 g (Bolivia). Distinctive species, adult with yellow forehead and chestnut underparts, with stubby bill thick and swollen. Nominate race has forehead and forecrown golden-yellow, feathers short, extremely dense and somewhat stiff and plushy (hence vernacular name), hindcrown and nape blackish; dusky lores, diffuse ocular area; entire upperparts, including scapulars and uppertail-coverts, bluish-grey; upperwing-coverts bluish-grey, primary coverts, flight-feathers and tail dusky, tinged brownish and edged dull bluish-grey; tail, strongly graduated, feathers pointed, with outer web very narrow;

side of head dusky chestnut, becoming rich chestnut on throat and underparts to undertail-coverts; iris dark brown; bill black; legs greyish horn, tinged brown. Sexes similar. Juvenile is very dull, forehead and forecrown dark grey, feathers slightly stiffened, upperparts dull greyish-olive, paler and tinged rufescent below; immature similar to juvenile, but hint of yellow on forecrown, especially on base of feathers, and plumage somewhat brighter. Race *federalis* closely resembles nominate, but slightly brighter overall, except for paler chestnut undertail-coverts, and golden area on forehead smaller and duller; *citrinifrons* has less yellow on head (yellow confined to forehead), the feathers not stiff and plush-like, and forehead bordered behind by narrow line of chestnut, underparts slightly paler than nominate, juvenile forehead and forecrown paler grey than nominate. Voice. Not often heard. Gives soft, high "chip" notes when foraging. In Peru, song a jerky, disjointed series of high-pitched, unmusical chips and twitters, "tseep-tseu-teep-ti-tsip-tseep...", duration 15–60 seconds, reminiscent of song of several *Hemispingus* tanagers. Call (Peru) a high "pseep" and "ti-ti-ti".

Habitat. Wet montane forest, dense forest borders, second growth, and elfin forest at or near tree-line; in all habitats mainly where *Chusquea* bamboo present. From c. 1800 m to 3500 m across broad Andean range (occasionally somewhat lower or higher), lowest elevations in coastal cordillera of N Venezuela, where occurs at c. 1800–2300 m; elsewhere in Venezuela 2300–2900 m, and from Colombia S to Bolivia generally c. 2000–3500 m.

Food and Feeding. Food apparently mostly small insects and other arthropods, perhaps some plant material, taken around the leafy bamboo internodes. Rather quiet and inconspicuous. Typically seen singly, or as loosely associated pair, or occasionally in family group of three individuals, travelling with mixed-species flocks containing small frugivores and insectivores; infrequently seen away from flocks with which it forages. Forages mainly in lower half of forest (c. 1–6 m up), where it keeps on the move, seldom remaining in view for more than a short time. Forages primarily in dense *Chusquea* bamboo, hopping actively up curving stems, often twisting or peering to the side as it examines leafy stem bases emerging from cane internodes; adept at hanging upside-down. Has been observed apparently to "bite" or squeeze stems of younger *Chusquea* bamboo as it hops up these canes, although food items that it seeks while doing this not known.

Breeding. Juvenile with adults in late Dec and immatures seen in early Feb in N Venezuela; fledglings reported in Oct in Colombia (Quindío), Jun in SE Ecuador and Jun–Aug at several localities in Peru, and juveniles/immatures reported May–Dec from S Colombia S to Bolivia; also, birds in breeding condition Jun–Jul in N Colombia; records suggest breeding mainly in wet season. No other information.

Movements. None reported. Apparently resident.

Status and Conservation. Not globally threatened. Uncommon to locally fairly common. Home range or foraging range may be fairly large, corresponding to area used by mixed-species flock which it follows, or sometimes larger. Occurs in numerous protected areas, among them Henri Pittier, Sierra Nevada and Tamá National Parks (Venezuela), Chingaza and Puracé National Parks and Tambito Nature Reserve (Colombia), Sangay and Podocarpus National Parks (Ecuador), Tingo María and Manu National Parks (Peru), and Madidi National Park (Bolivia). The species occurs also in many unprotected areas, some of which probably at little near-term risk, but logging, human settlement, and deforestation for agriculture and cattle pasture have greatly reduced and fragmented the area of habitat available to it. In particular, race *federalis*, confined to narrow spine of N cordillera in Venezuela, may be at risk because of the small amount of suitable bamboo habitat remaining.

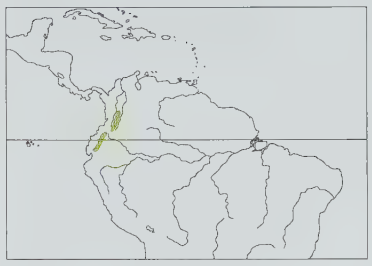
Bibliography. Anon. (2000), Bledsoe (1988), Di Giacomo *et al.* (1997), Donegan & Dávalos (1999), Echeverry-Galvis & Córdoba-Córdoba (2007), Fjeldså & Krabbe (1990), Hellmayr (1938), Hilty (2003), Hilty & Brown (1986), Hilty *et al.* (1979), Krabbe, Flórez *et al.* (2006), Krabbe, Moore *et al.* (2001), Meyer de Schauensee (1970a), Moore *et al.* (1999), Narosky & Di Giacomo (1993), Phelps & Phelps (1950), Restall *et al.* (2006), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schäfer & Phelps (1954), Schulenberg *et al.* (2007), Walker (2001), Yuri & Mindell (2002).

Genus *UROTHRAUPIS*

Taczanowski & Berlepsch, 1885

209. **Black-backed Bush-tanager**

Urothraupis stolzmanni



French: Urotangara de Stolzmann **German**: Stolzmanntangare **Spanish**: Tangara de Stolzmann
Other common names: Black-backed Finch/Brushfinch

Taxonomy. *Urothraupis stolzmanni* Taczanowski and Berlepsch, 1885, Hacienda San Rafael, 9000 feet [c. 2740 m], Volcán Tungurahua, Ecuador.

Relationships uncertain; considered by some authors to be most closely allied to *Chlorospingus*, but regarded by some others as belonging in family Emberizidae and possibly closest to *Atlapetes*; molecular-genetic data indicate that it probably belongs in present family. Monotypic.

Distribution. Colombia in C Andes (Caldas and Cauca, and from Nariño) S to SC Ecuador (Tungurahua).

Descriptive notes. 15 cm; 19–27 g (Ecuador). Rather short-billed species with slightly graduated tail. Has crown and side of head to well below eye black, upperparts to uppertail-coverts and tail dull black; upperwing-coverts blackish, vaguely tinged brown and faintly edged brown-grey, edging more conspicuous and palest on outer primaries, often also on tertials; throat white, often somewhat puffed and sharply contrasting with dark side of head; chest whitish, mottled and flecked with grey, gradually becoming grey on lower breast and belly; flanks and undertail-coverts darker sooty-grey; iris dark brown; bill blackish; legs dark grey. Sexes similar. Juvenile undescribed. Voice. During foraging, high-pitched, soft "tsit", "see", "sic" and "tic" notes, singly or occasionally a note doubled, or in brief, thin trill. (These call notes differ little, if at all, from those given by many other high-elevation associates, e.g. *Iridosornis* and *Hemispingus*.) No song recorded.

Habitat. Dense wet forest, wooded borders, and stunted woodland up to tree-line, especially where many dense bushes and shrubs present. In Ecuador mainly near tree-line and, on E side of Andes, in patches of *Polylepis*-dominated woodland. Recorded mostly at c. 3000–3600 m (rarely as low as 2750 m) in Colombia and c. 3200–4000 m in Ecuador.

Food and Feeding. Diet little known; apparently a mixture of insects and small berries and fruits. Occurs in groups of 3–6 individuals, occasionally up to nine, either alone or with mixed-species flocks containing New World warblers (Parulidae), other tanagers and emberizids. Although it forages in dense foliage, it regularly searches near tips of branches, where more easily seen. Forages actively, perch-gleaning, or stretching to peer above and below leaves; also works foliage and dense vegetation in manner of a tit (Paridae), gleaning, probing and occasionally hanging briefly near branch tip.

Breeding. No information.

Movements. Resident.

Status and Conservation. Not globally threatened. Restricted-range species: present in Central Andean Páramo EBA. Uncommon and local. Occurs in Puracé National Park, in Colombia; perhaps also in parts of Llanganates, Cajas and Sangay National Parks, in Ecuador. Within this species' range, extensive deforestation and firewood-cutting of tree-line vegetation has greatly reduced amount of habitat available. Distribution now spotty and local in both Colombia and Ecuador.

Bibliography. Bledsoe (1988), Chapman (1917, 1926), Dunning (1982), Fjeldså & Krabbe (1990), Hilty & Brown (1986), Isler & Isler (1999), Krabbe *et al.* (2001), Meyer de Schauensee (1951, 1952b, 1964, 1966, 1970a), Ridgely & Greenfield (2001a, 2001b), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Sibley & Ahlquist (1990), Spencer (2008b), Strewe & Kreft (1999).

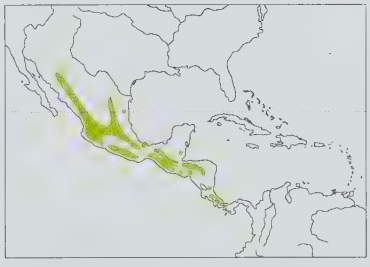
Genus *EUPHONIA* Desmarest, 1806

210. **Blue-hooded Euphonia**

Euphonia elegantissima

French: Organiste à capuchon **German**: Blaukappenorganist **Spanish**: Eufonia Elegante
Other common names: Elegant/Blue-rumped Euphonia

Taxonomy. *Pipra elegantissima* Bonaparte, 1838, Mexico.



Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Present species forms a monophyletic species group with *E. cyanocephala* and *E. musica*, and all formerly considered conspecific; widely separated geographically, the three do not differ greatly in voice or behaviour, although males differ somewhat in plumage, females less so. Race *vincens* poorly differentiated, and perhaps better subsumed in nominate. Three subspecies tentatively recognized.

Subspecies and Distribution.

E. e. rileyi (van Rossem, 1942) – NW Mexico (SE Sonora and NE Sinaloa).

E. e. elegantissima (Bonaparte, 1838) – W & C Mexico (from S Sinaloa, Guanajuato and S Tamaulipas) S, mainly in mountains, to Belize, C & S Guatemala, Honduras, El Salvador and CN Nicaragua.

E. e. vincens E. J. O. Hartert, 1913 – SW Nicaragua and mountains of Costa Rica and W Panama (E to Veraguas).

Descriptive notes. 10 cm; 13–17 g. Small-billed euphonia, male with orange-rufous underparts. Male nominate race has rufous forehead bordered behind by pencil-thin line of black; crown and nape bright turquoise-blue, the blue extending down side of neck behind ear-coverts; side of head and throat black; upperparts, including upperwing-coverts, flight-feathers and tail, glossy purplish-black; underparts tawny-orange, darkest on chest; underwing-coverts white; iris dark brown; bill blackish, greyish base of lower mandible; legs dusky grey. Female has forehead rufous, bright sky-blue crown and nape, blue curling down onto side of neck behind ear-coverts (as on male), side of head olive; upperparts bright olive-green; upperwing-coverts mostly olive-green, flight-feathers dusky, edged olive-green; tail dull dark olive-green; throat washed cinnamon, becoming yellowish-olive on breast and sides and greenish-yellow on centre of belly and undertail-coverts. Juvenile is like female, male with cinnamon-tinged chin and contrasting blue-black flight-feathers; immature male much like adult female, but slightly duller, and with blue restricted to crown (not reaching nape). Race *rileyi* male more steely-blue above, with duller hood, female greyer above and generally duller (less green and yellow) than nominate; *vincens* male has crown distinctly lighter blue than nominate, female intermediate between those of other races. Voice. Song a long, fast jumble of little trills, bubbly notes, whistles and chips in rambling fashion. Calls include variety of reedy and tinkling notes, some sharp, some soft and mellow; frequently a soft plaintive "pee".

Habitat. In Mexico occurs in open pine–oak (*Pinus–Quercus*) woodland, oak scrub, borders of broadleaf evergreen forest, and plantations, also scattered trees in clearings near forest and in all areas often in trees with mistletoe (Loranthaceae). In Costa Rica and W Panama mainly in humid

On following pages: 211. Golden-rumped Euphonia (*Euphonia cyanocephala*); 212. Antillean Euphonia (*Euphonia musica*); 213. Jamaican Euphonia (*Euphonia jamaica*); 214. Plumbeous Euphonia (*Euphonia plumbea*).

montane forest and along forested borders and second growth. Mainly at 1000–2500 m, in Mexico regularly down to 500 m, lower in non-breeding period, and in Costa Rica post-breeders regularly to as low as 750 m on Caribbean slope; locally from almost sea-level to 3050 m in Panama, but most numerous c. 1050–1500 m.

Food and Feeding. Feeds almost entirely on small soft berries, principally of mistletoe; exocarp sometimes removed before eating. Pairs or small groups, occasionally up to c. 9–10 individuals, spend long periods of time in or near clumps of mistletoe, and may fly off long distances in search of other trees with suitable clumps of mistletoe. Reported roosting associations of up to 50 or more individuals sleeping in close proximity in dense foliage, dispersing at dawn.

Breeding. Insufficient data on season. Rounded or globular nest with side entrance, finely woven with slender rootlets and dry grass stems, lined with finer grass; up to 18 m above ground in niche on high bank or in moss, *Tillandsia*, or epiphytes on trunk, limb or branch fork. Clutch 3 eggs, creamy white, thickly or sparsely dotted brownish or purplish, especially at larger end. No other information.

Movements. Birds from N part of range in Mexico may migrate S during coldest months; also descends to lower levels in non-breeding period. In Costa Rica regularly makes post-breeding descent on Caribbean slope, and in Panama post-breeding downslope movements into lowlands reported.

Status and Conservation. Not globally threatened. Fairly common over most of range. Survives in variety of semi-open or disturbed montane habitats, and also occurs in a number of protected areas, including Sierra de Manantlán Biosphere Reserve and Volcán Nevado de Colima and Cañon del Sumidero National Parks, among others, Mexico, Cerro El Baúl and Los Aposentos (near Chimaltenango), in Guatemala, and Celaque National Park, in Honduras. The species' range contains much suitable habitat which is unprotected, but with little short-term risk of development.

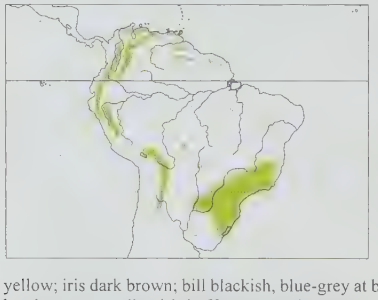
Bibliography. Anon. (1998), Baepler (1962), Binford (1968, 1989), Blake (1956), Carriker (1910), Davis (1972), Dickey & van Rossem (1938), Edwards (1972), Garrigues & Dean (2007), Howell & Webb (1995), Isler & Isler (1999), Land (1970), Monroe (1968), Ogilvie-Grant (1912), Rand & Traylor (1954), Ridgely & Gwynne (1989), Robins & Heed (1951), van Rossem (1945), Schaldach (1963), Slud (1964), Stiles & Skutch (1989), Wetmore *et al.* (1984).

211. Golden-rumped Euphonia

Euphonia cyanocephala

French: Organiste doré **German**: Goldbürzelorganist **Spanish**: Eufonia Culidorada

Taxonomy. *Pipra cyanocephala* Vieillot, 1819, Trinidad.



Species sometimes referred to by name *E. aureata*, but present name has priority. Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Present species forms a monophyletic species group with *E. elegantissima* and *E. musica*, and all formerly considered conspecific; widely separated geographically, the three do not differ greatly in voice or behaviour, although males differ somewhat in plumage, females less so. Taxonomic status of population of present species in SE Brazil, Paraguay and NE Argentina seems worthy of investigation because of its extreme isolation. On the other hand, proposed race *intermedia* (described from NE Colombia) is difficult to diagnose; measurements overlap with those of nominate, and no certain colour differences separate it from latter, into which it is therefore subsumed. Three subspecies recognized.

Subspecies and Distribution.

E. c. pelzelni P. L. Sclater, 1886 – S Colombia and W Ecuador (S to Chimborazo).

E. c. insignis P. L. Sclater & Salvin, 1877 – E slope of Andes in Ecuador (Azuay and Loja).

E. c. cyanocephala (Vieillot, 1819) – Sierra de Perijá (Colombia–Venezuela border) and Venezuela (Andes, coastal cordilleras, and locally SE Bolívar) E locally through C Guyana, Suriname and French Guiana; Trinidad; and Andes of Colombia (except S), probably E slope in Ecuador, entire E slope in Peru S to Bolivia (also extreme E Santa Cruz) and NW Argentina (S to Tucumán; sight records to Córdoba–San Luís border; isolated record N of Buenos Aires); also NC & SC Brazil (isolated records in Pará and W Mato Grosso); also SE Brazil (Bahia, S Goiás and S Mato Grosso S to Rio Grande do Sul), SE Paraguay and NE Argentina (W to E Chaco).

Descriptive notes. 11 cm; 15–16 g. Small euphonia with blue cap and golden rump. Male nominate race has forehead and face (from top of eye) extending back across ear-coverts and down to throat black; crown and nape bright turquoise-blue, the blue curling down from nape onto side of neck behind ear-coverts; mantle and back black with purplish to dark blue gloss, lower back and rump golden-yellow to orange-yellow, uppertail-coverts blue-black; upperwing-coverts and tertials dusky black with dark bluish tinge, flight-feathers dark brown to dusky with dull yellowish-olive margins and outer webs; underparts deep yellow; iris dark brown; bill blackish, blue-grey at base; legs dusky grey. Female has basal forehead band tawny to yellowish-buff, crown and nape turquoise-blue (as on male); otherwise mostly olive-green above, paler and brighter on rump; flight-feathers and tail dark fuscous, edged olive-green; side of head and ear-coverts olive-green, like back, chin to lower breast yellow-olive, turning more yellowish (olive-yellow) on belly and undertail-coverts. Juvenile is much like female, but duller, juvenile male with narrow basal forehead band dull orangish, and crown olive, strongly tinged blue and vaguely scaled greyish, juvenile female with forehead band yellowish. Race *pelzelni* is very slightly larger than nominate, male rump and underparts paler; *insignis* male differs in having forehead band orange-yellow with narrow black line behind, female has slightly greener back than nominate. Voice. Song in Venezuela and Colombia, lasting up to c. 10 seconds (occasionally to 30 seconds), a very fast, complex stream of twittery and squeaky notes mixed with low-pitched "chup" notes. Call a soft whistled "cheeer", slightly descending, much like call of *Chlorophonia cyanea*, but lower-pitched, and this note sometimes repeated several times in succession; in SE Brazil call described as a slow series of 3–4 whistles, song a fast, varied warble. In all areas, fast and complex song is often mixed with call notes.

Habitat. Forest borders, second-growth woodland, disturbed or partially open areas, and shady coffee plantations, mainly in mountains. Occurs in both humid and fairly dry regions, but generally not inside forest. In N Andean portion of range (Venezuela, Colombia) mainly 600–2500 m, occasionally or seasonally down to sea-level, and locally up to 3250 m in SW Colombia; mostly 1200–2700 m in Ecuador, with scattered records down to 700 m and as high as 3000 m; recorded at 500–2800 m in Peru and at similar elevations in Bolivia and N Argentina; in SE Venezuela and across C Guianan region mainly 500–1500 m; in SE Brazil and adjacent areas mainly lowlands and lower montane elevations.

Food and Feeding. Almost entirely frugivorous, apparently also some insects. One stomach contained only fruit pulp. Seeds pass rapidly through gut; mistletoe seeds (Loranthaceae) typically voided as long sticky, tapioca-like strings, which readily adhere to twigs and branches. Pairs or groups of 3–8 individuals spend much of their time in large clumps of fruiting mistletoe in canopy of trees, where rather quiet (or give soft calls) and keep mostly to themselves; occasionally joined by other euphonias in mistletoe, and only infrequently or incidentally associate with mixed-species flocks. After feeding in a tree, may fly off considerable distance to another site. Occasionally seen while apparently searching for insects in canopy foliage.

Breeding. Nests in Jan and Feb in Venezuela (Aragua and Trujillo); and two nests in Apr and May and 13 birds in breeding condition Dec–May in Colombia. Nest a globular dome of grass and moss, with side entrance, concealed on bank of road cutting or 4–8 m up on epiphyte-laden trunk or branch of small to large tree, most often at forest edge. Clutch 2 eggs, cream, marked light reddish-brown and black, mostly at larger end. No other information.

Movements. Believed to wander locally when not breeding. Possible seasonal movements to lower elevation, but not yet well documented.

Status and Conservation. Not globally threatened. Uncommon to fairly common; local. Occurs over a wide range of elevations and habitats, including many non-forest, forest-edge and human-altered habitats; found also in many protected areas. Because of severe deforestation in Atlantic coastal region of SE Brazil, and in NE Argentina, populations in this region are much more dependent upon existing reserves and parks, e.g. Itatiaia National Park, than elsewhere in its range.

212. Antillean Euphonia

Euphonia musica

French: Organiste louis-d'or **German**: Antillenorganist **Spanish**: Eufonia Antillana
Other common names: Blue-crowned Euphonia

Taxonomy. *Pipra musica* J. F. Gmelin, 1789, Santo Domingo, Dominican Republic.

Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Present species forms a monophyletic species group with *E. elegantissima* and *E. cyanocephala*, and all formerly considered conspecific; widely separated geographically, the three do not differ greatly in voice or behaviour, although males differ somewhat in plumage, females less so. Three subspecies recognized.

Subspecies and Distribution.

E. m. musica (J. F. Gmelin, 1789) – Hispaniola and Gonâve I.

E. m. sclateri (P. L. Sclater, 1854) – Puerto Rico.

E. m. flavifrons (Sparrman, 1789) – Lesser Antilles on Barbuda, Antigua, Guadeloupe, La Désirade, Dominica, Martinique, St Lucia, St Vincent, and Grenada.

Descriptive notes. 10 cm; 12·4–16 g, eight birds from Guadeloupe 13·4–18·5 g. Small euphonia with short thick bill. Male nominate race has lores, side of head including ear-coverts, and chin and throat blackish-violet, small forehead band tawny-yellow, crown and nape lustrous sky-blue, blue of nape extending down behind rear ear-coverts; mantle and back black, glossed dark blue, rump and uppertail-coverts rich tawny-yellow; upperwing-coverts, flight-feathers and tail dull black, wing-coverts glossed dark blue, flight-feathers edged slightly paler blue; underparts, including undertail-coverts, rich tawny-yellow; iris dark brown; bill black, base of lower mandible blue-grey; legs dark grey. Female has yellow forehead, dull bluish crown and nape, olive upperparts; yellowish throat becoming dull olive-yellow on breast and rest of underparts. Juvenile resembles female, typically somewhat duller. Race *sclateri* male differs from nominate in having forehead patch slightly deeper yellow, rump bright yellow, and entire underside, including throat, paler yellow (no black on throat); *flavifrons* male is hen-plumaged, thus resembles female of nominate, mainly olive above with blue crown and nape, small yellow forehead patch and throat, olive-yellow below, slightly paler and yellower on throat and belly. Voice. Song a trilling, tinkling "tuc-tuc-tuc...", punctuated with sharp whistles, often in long rambling discourse for up to 20 minutes with little or no pause. Calls during foraging include a plaintive whistle, i.e. "whee", a scolding "chit-it", a hard metallic "chi-chink", and softer "tuc-tuc". Both sexes commonly give a sharp whistle followed by several rapid double notes (forming a chatter), especially when they fly.

Habitat. Occurs in dry to humid and wet forest and along borders and disturbed areas, wherever mistletoe (Loranthaceae) present. Recorded at all elevations from lowlands to high mountains throughout range; believed to breed mainly at higher elevations, and apparently primarily a wanderer or seasonal non-breeding visitor to lower elevations.

Food and Feeding. Small fruits, e.g. on St Vincent reported as eating buds of silk-cotton tree (*Bombax*); believed to eat catkins of *Cecropia* in Puerto Rico. Contents of 51 stomachs were vegetable matter, including seeds of several species of mistletoe. Occurs in pairs when breeding, but at other times in small groups of up to a dozen individuals during day; reported as roosting in groups of up to dozens during non-breeding season. Moves actively in treetops, remaining especially in dense foliage and in mistletoe clumps.

Breeding. Season Jan–Jul. Nest a grassy domed structure with side entrance, usually well concealed in moss and epiphytes in tree; on St Vincent, nest made from moss and rootlets, inner cup of dried grass and shredded plant material, placed 9 m up and attached to vine growing against trunk of forest palm; one nest in Puerto Rico was in thick shoots of a mango tree (*Mangifera*). Clutch 4 eggs, white, spotted with mauve. No other information.

Movements. Chiefly resident. Seasonal elevational movements between highlands and lowlands reported, as yet not well documented. Some intra-island movement recorded; race *flavifrons* a vagrant on St Barthélemy, St Christopher, Montserrat and the Grenadines.

Status and Conservation. Not globally threatened. Restricted-range species: present in Hispaniola EBA, Puerto Rico and the Virgin Islands EBA and Lesser Antilles EBA. Common in most of Hispaniola, including Gonâve I, and Puerto Rico; uncommon in Lesser Antilles. Population in Haiti threatened as a result of extensive deforestation. Lesser Antilles race (*flavifrons*) believed to

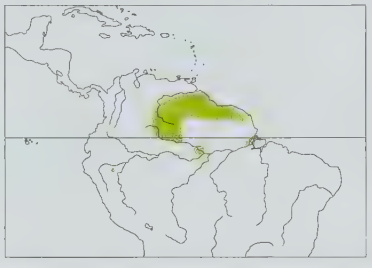
be extinct on Saba, from where no recent records, and perhaps generally in decline over much of range, e.g. few or no recent records from St Vincent.
Bibliography. Anon. (1998), Biaggi (1970), Bond (1928a, 1928b, 1961, 1982), Bowdish (1903), Clark (1905), Diamond (1973), Dod (1978), Leck (1972a), Olson & Angle (1977), Pérez-Rivera (1992a, 1992b), Raffaele (1983), Raffaele *et al.* (1998), Reynard (1982), Wetmore (1927), Wetmore & Swales (1931).

213. **Jamaican Euphonia**

Euphonia jamaica

French: Organiste de Jamaïque **German**: Gimpelorganist **Spanish**: Eufonia Jamaicana

Taxonomy. *Fringilla jamaica* Linnaeus, 1766, Jamaica.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Monotypic.
Distribution. Jamaica.



Descriptive notes. 11 cm; c. 17 g. Small, plain greyish euphonia with notably short, thick bill. Male is mainly bluish-grey (can look rather bluish in good light), narrow area at bend of wing yellow (usually hidden), upperwing-coverts, flight-feathers and tail dusky, tinged or glossed bluish; throat and underparts grey, slightly paler than upperparts, and becoming yellow on centre of lower breast and belly and buffy yellow on undertail-coverts; iris dark brown; bill pale bluish-grey, with black culmen, cutting edges and tip; legs dusky grey. Female is "bicoloured", with grey foreparts and olive rear parts; back, rump and tail olive; flight-feathers dusky, glossed green, outer primaries edged yellow, tertials mainly dull olive-green; head and underparts grey, head slightly darker, throat whitish, paler than head and chest, and belly and undertail-coverts tinged buff, flanks tinged olive. Immature is similar to female, but slightly duller. Voice. Song a sweet, musical "chur-chur-chur-chur-chur-chwit", last note rising, or sometimes last note omitted. Also variety of other notes, some chuckling, some mewing, some harsh or chattery, and others squeaky like those of a hummingbird (Trochilidae).
Habitat. Woodland, borders, open or shrubby areas with trees, gardens and orchards; most common in open second growth in hilly lowlands. From sea-level to c. 2250 m (Blue Mountain Peak).
Food and Feeding. Mostly small fruits and berries, especially mistletoe berries (Loranthaceae), last-mentioned forming a major part of diet; reported also as taking fruit of figs (*Ficus*), *Cecropia*, *Dunalia*, guava (*Psidium*), and fruit of cho-cho vines (*Sechium*). May forage in small flocks, or gather with other birds at feeding sites, where it sometimes acts aggressively; seasonally, gathers in small groups to roost. Forages in canopy and upper levels of trees; active, sometimes takes fruits in acrobatic manner.
Breeding. Reported season Feb–May. Nest built by both sexes, a domed structure with side entrance, made from mixture of grass, stems and vegetable down, much like that of other members of genus, often concealed in Spanish moss (*Tillandsia*) and at almost any height. Clutch 3–4 eggs, white, marked with lavender, purplish-red or reddish-brown, especially at large end. No other information.
Movements. Resident. Reported to undertake seasonal movements around the island.
Status and Conservation. Not globally threatened. Restricted-range species: present in Jamaica EBA. Common and widespread. No population trends available, but seems to be at little short-term risk. Probably occurs in most of Jamaica's numerous forest reserves (many of which are quite small). An important disperser of mistletoe seeds. Because it is so heavily frugivorous, this species may, especially when in flocks, damage cultivated fruit crops in gardens and orchards.
Bibliography. Bond (1961), Cruz (1974, 1981), Danforth (1928), Field (1894), Gosse (1847), Isler & Isler (1999), Jeffrey-Smith (1956), March (1863), Ogilvie-Grant (1912), Raffaele *et al.* (1998), Taylor (1955).

214. **Plumbeous Euphonia**

Euphonia plumbea

French: Organiste plombé **German**: Grauorganist **Spanish**: Eufonia Plúmbea

Taxonomy. *Euphonia plumbea* du Bus de Gisignies, 1855, la Nouvelle-Grenade; error = Guyana.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Monotypic.
Distribution. E Colombia (Serranía Chiribiquete E to Vichada and Guainía), N Brazil (upper R Negro), and Venezuela S of R Orinoco E to French Guiana; small isolated populations in NE Peru (San Martín; possibly also N Loreto) and N Brazil in Amazonas (W of lower R Negro) and S Amapá.

Descriptive notes. 9 cm; 8·7–9·5 g. Small, plain euphonia lacking yellow forehead; bill short and stubby. Male has entire head down to throat and upper chest and entire upperparts glossy dark grey, sharply separated from bright yellow breast and lower underparts; upperwing-coverts and flight-feathers dusky, broadly edged olivaceous grey, tail dusky, washed olivaceous grey; sides and flanks somewhat mottled with grey, underwing-coverts white; iris dark brown; bill blackish, becoming grey at base; legs dark grey. Female is patterned like male, but duller, mainly yellowish-grey above, rump and uppertail-coverts paler and more yellowish, crown and nape grey; upperwing-coverts, flight-feathers and tail dark olive; throat and chest pale grey with faint yellow tinge, lower underparts olive-yellow, undertail-coverts pale olive, washed with yellow. Immature is much like female. Voice. Often heard calls include a single clear whistled "wheet", or doubled "dee-dee" and "dee, dee-dee", the two last-mentioned much like the "beem-beem" calls of many other members of genus. Songs and calls may be intermixed. Song, infrequently heard, a rather squeaky, jumbled "o'fiddle-de-wéét!" in S Venezuela (Amazonas); in a variation, described as "wéét sweet-a-swee-swee", first note whistled, rest rapid and jumbled.
Habitat. Occupies open scrubby woodland, savanna-forest borders, bushes and scattered trees in savanna, and scrubby vegetation around large rock outcrops, mainly in regions with white-sand soil. Primarily found in lowlands, up to 1000 m in SE Venezuela; elsewhere at similar elevations, and up to 1500 m.
Food and Feeding. Feeds mainly on small fruits and berries; unlike some congeners, seems not to show any particular affinity for mistletoe berries (Loranthaceae), which are scarce in this species' habitat. Most often seen in pairs or in families of 3–4 individuals; sometimes spends considerable time in a tree and then flies off swiftly to another tree, often some distance away.
Breeding. Apparently no information available.
Movements. Resident. Believed to wander rather widely seasonally, hence can be erratic and unpredictable in occurrence; no evidence of elevational movements.
Status and Conservation. Not globally threatened. Uncommon to fairly common; widely, if rather sparsely, distributed across white-sand regions of Roraiman and Guianan areas. Occurs in several large protected areas, including Canaima, Duida-Marahuaca, Jaua-Sarisariñama and Serranía de la Neblina National Parks (Venezuela), Kaieteur National Park (Guyana), Sipaliwini Nature Reserve (Suriname) and probably also Pico da Neblina National Park (NW Brazil). The species' range also includes extensive intact habitat which is unprotected, but with little short-term risk of development. Prominent among these unprotected areas are Kanuku Mts, in Guyana, and the extensive white-sand soil belt running through NC Suriname.

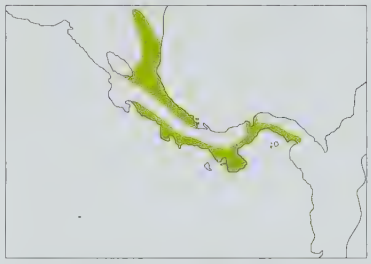
cm 5

215. Scrub Euphonia

Euphonia affinis

French: Organiste de brousse **German**: Buschorganist **Spanish**: Eufonia Matorralera
Other common names: Lesson's/Black-throated Euphonia; Pale-vented/Godman's Euphonia (*godmani*)

Taxonomy. *Tanagra* [*Euphonia*] *affinis* Lesson, 1842, Realjo, Nicaragua.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. May form a monophyletic species group with *E. luteicapilla*, *E. chlorotica* and *E. trinitatis*. Three subspecies recognized.
Subspecies and Distribution.
E. a. olmecorum Dickerman, 1981– Gulf slope of Mexico from S Tamaulipas and E San Luis Potosí S to N Chiapas.
E. a. godmani Brewster, 1889 – Pacific slope of Mexico from SE Sonora S to C Guerrero.
E. a. affinis (Lesson, 1842) – Yucatán Peninsula and Cozumel I S through Belize and Guatemala to N Honduras; Pacific slope of Mexico from W Oaxaca S along coast to NW Costa Rica (Guanacaste).



Descriptive notes. 9 cm; 8·5–12·8 g. Small, short-tailed euphonia with black-and-yellow pattern typical of many in genus; bill short and stubby. Male nominate race has forehead to eye bright yellow (appearing as small, relatively restricted patch), rest of head and down to foreneck glossy blue-black with purplish sheen; upperparts glossy blue-black, median and greater upperwing-coverts, flight-feathers and tertials blackish, somewhat glossed dark blue; breast, belly and undertail-coverts bright yellow, underwing-coverts white; tail blackish, inner webs of outer two tail feathers white (from below, showing as large oval-shaped patch on each side of tail); iris dark brown; bill blue-grey with blackish tip; legs dark grey. Female has forehead olive-yellow, becoming greyish on rest of crown and nape; upperparts olive, grey tinge on back; side of head and most of underparts olive-yellow, turning to yellow on belly and undertail-coverts. Juvenile is much like female, but male head olive and may show blue-black flight-feathers; immature male like adult female, but head olive; subadult male olive like female, typically acquires black on face and head after c. 1 year, thereafter may show variable amount of black mottling mixed with olive on back and underparts; male may require 2 years to gain adult plumage. Race *godmani* differs from nominate in having white (not yellow) undertail-coverts, female slightly paler overall, with centre of belly and undertail-coverts white, flanks yellowish, undertail with more white than in nominate; *olmecorum* male is very like male of nominate, female differs from nominate in being overall paler. Voice. Call of 1–3 pure thin whistles, "dee-dee-dee", sometimes followed by 2 or 3 more on same or slightly lower pitch; also gives shorter "whit-it-it-it" and longer "wheeee". Song, less often heard, a weak twittering and chirping medley, e.g. "wheetidy-titity-witity-titity". In Mexico slight vocal differences between nominate race and *godmani* have been noted, calls of latter being brighter and less plaintive.
Habitat. Variety of semi-open, drier or lightly wooded areas, including dry forest, forest borders, second growth, scrub, cultivated areas, and pastures with scattered trees, as well as humid forest borders, riverine forest, gardens and clearings; not found inside moist or humid forest. Reported from sea-level to 2250 m, mostly below 1000 m.
Food and Feeding. Primarily frugivorous, taking berries of mistletoe (Loranthaceae) and many other small fruits, including figs (*Ficus*), *Muntingia* (Elaeocarpaceae) and *Neea* (Nyctaginaceae); reported as feeding also on variety of cultivated fruits, such as oranges and bananas, when these opened by larger birds. Also some insects, and noted once with a large grasshopper (Caelifera). Ten stomachs all contained vegetable matter, mostly of mistletoe berries. Occurs in pairs and small groups, frequently in association with *E. hirundinacea*. Forages for insects by examining undersides of thin twigs, sometimes wagging its half-spread tail from side to side as it moves.
Breeding. Nest with eggs in May in Mexico; breeding reported in dry season, Nov–Apr, in Costa Rica. Covered, football-shaped nest with side entrance, made from grass stems, leaf petioles, bits of leaves, bark and fine rootlets, lined with fungal fibres, 3·5–8 m up on horizontal branch, in fork of sapling, or wedged in fork beneath large dead leaf of *Cecropia*. Clutch in Costa Rica 2–3 eggs, white to buffy white with reddish-brown spots or paler blotches, forming wreath or cap; eggs in Mexico nest reportedly pale greenish-blue. No other information.
Movements. Resident. Some local wandering likely during post-breeding period.
Status and Conservation. Not globally threatened. Widespread and fairly numerous throughout its mainly lowland range. Status in El Salvador, which is almost entirely deforested, is uncertain, although this species should formerly have occurred across at least W third of country. Can be expected to occur in numerous protected areas, especially in Mexico, N Guatemala, Belize and W Nicaragua. The species thrives also in drier settled or disturbed areas, so long as there are scattered trees and woodlots. Appears to be at little risk in the short term, although may be declining locally where destruction of tropical dry forest is extensive.
Bibliography. Andrle (1967), Brush (2009), Davis, L.I. (1972), Davis, J. (1960a), Dickerman (1981b), Dickey & van Rossem (1938), Edwards (1972), Eisenmann (1955), Garrigues & Dean (2007), Howell & Webb (1995), Klaas (1968), Land (1970), Ogilvie-Grant (1912), Paynter (1955), Rand & Traylor (1954), Rowley (1966), Russell (1964), Salvin & Godman (1883), Skutch (1980b), Slud (1964), Smithe (1966), Stiles & Skutch (1989), Sutton (1951a, 1951b), Wetmore (1944).

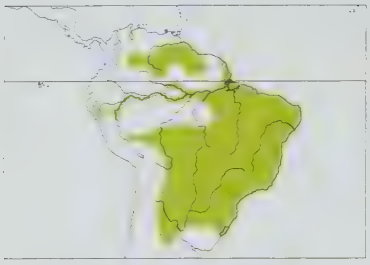
216. Yellow-crowned Euphonia

Euphonia luteicapilla

French: Organiste à calotte jaune **Spanish**: Eufonia Coronigualda
German: Gelbscheitelorganist

Taxonomy. *Phonasca luteicapilla* Cabanis, 1861, Costa Rica.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. May form a monophyletic species group with *E. affinis*, *E. chlorotica* and *E. trinitatis*. Monotypic.
Distribution. Caribbean lowlands from E Nicaragua S to NW Panama (Bocas del Toro, and around Canal Zone) and Pacific slope from NW Costa Rica (Guanacaste) S to E Panama (C Darién).

Descriptive notes. 9 cm; 11·4–14·5 g. Small, short-tailed euphonia with short stubby bill. Male has forehead and mid-crown to well behind eye yellow, forming large contrasting yellow crown patch; rest of head down to foreneck and entire upperparts glossy blue-black, upperwing-coverts, flight-feathers and tail blue-black (like back); breast to undertail-coverts entirely bright yellow, underwing-coverts white; iris dark brown; bill blue-grey with blackish tip; legs dark grey. Female is olive above, with yellowish tinge on forehead, plain olive-yellow below, slightly paler in centre, becoming duller on belly and undertail-coverts. Immature is like female; subadult male may have forecrown mottled olive, some black on face and throat, and has throat and chest yellowish, rest of underparts olive. Voice. Call a series of 2–3 clear high whistled notes that may be given at varying speed, "bee-bee-bee", or in longer series, e.g. "beebee, peepeepee", second part slightly lower in pitch. Staccato "tsit" notes in flight or as contact among members of foraging group. Song a short, dry sputtering series of notes, e.g. "pit ditrééa-twiddledee bee bee"; described also as a short wiry "chut-tsip ts'tsew tsiuweer" or similar phrase.
Habitat. In dry to humid regions, mainly in semi-open areas with scattered trees, pastures, cultivated areas, old clearings, and second growth. Occurs in humid areas mainly in Nicaragua and Costa Rica, where predominantly along forest borders and semi-open areas with scattered trees (not inside tall humid forest). In Panama found in dry and scrubby areas, dry wooded borders, or areas with extensive clearings and scattered trees; scarce in heavily forested areas. Lowlands and foothills to c. 900 m; rarely to 1600 m in Panama.
Food and Feeding. Mistletoe berries (Loranthaceae) and some other small fruits; probably some insects. Found singly, in pairs, and in groups of three or four individuals that may roam about over rather large areas; may gather with other species at fruiting trees. Generally stays high in trees, where it has been reported as examining small bare twigs for insects.
Breeding. Season mostly Feb–May (extreme dates Jan–Jul) in Costa Rica, and breeding reported in Mar in Panama; sometimes two broods in Costa Rica. Nest constructed by both sexes, in Costa Rica a small globular structure with narrow rounded side entrance, made from fine rootlets, petioles, dead leaves, moss and grass stems, lined with finer grasses and animal hair or other soft material, placed in cranny in stump, fence post or similar, or among orchids or epiphytes, or in cluster of twigs, 1–30 m (usually c. 2–3 m) above ground. Clutch 3 eggs, occasionally 2–4, white, heavily mottled with brown; incubation by female, period 13–14 days; chicks fed by both adults, by regurgitation, nestling period notably long, 22–24 days. Male may breed when still in subadult plumage.
Movements. Resident. Some seasonal elevational movement reported in Costa Rica.
Status and Conservation. Not globally threatened. Fairly common. Thrives in variety of drier semi-open areas, including areas partly opened up by human activities. Occurs also in numerous protected areas, including e.g. Santa Rosa, Palo Verde Carara, Manuel Antonio and Tortuguero National Parks (Costa Rica) and Chiriquí, Sarigua and Metropolitan National Parks (Panama). Found also in many unprotected areas, including e.g. rural Monteverde (Costa Rica), that are of little risk of development.
Bibliography. Carriker (1910), Davis (1972), Eisenmann (1955), Hartman (1955), Isler & Isler (1999), Ridgely & Gwynne (1989), Ross & Whitney (1995), Skutch (1954), Slud (1964), Stiles & Skutch (1989), Strauch (1977), Wetmore *et al.* (1984).



217. Purple-throated Euphonia

Euphonia chlorotica

French: Organiste chlorotique **German**: Purpurkehlorganist **Spanish**: Eufonia Golipúrpura

Taxonomy. *Tanagra chlorotica* Linnaeus, 1766, Cayenne, French Guiana.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. May form a monophyletic species group with *E. affinis*, *E. luteicapilla* and *E. trinitatis*; has in the past been regarded as conspecific with last-mentioned, but differs in habitat and in female plumage. Geographical distribution of some races poorly defined, and ranges listed below somewhat tentative; further study required. Five subspecies recognized.
Subspecies and Distribution.
E. c. cynophora (Oberholser, 1918) – W & S Venezuela (S Táchira, and E to Amazonas and Bolívar E to R Caura and R Cuyuní) S to E Colombia (Meta), probably also N Brazil (N Roraima).
E. c. chlorotica (Linnaeus, 1766) – the Guianas and NC & E Brazil (E & S Amapá, and S of R Amazon from R Tapajós E through N Mato Grosso, Goiás and Minas Gerais to Bahia and Espírito Santo).
E. c. amazonica Parkes, 1969 – both banks of R Amazon E from SE Colombia and extreme NE Peru to NC Brazil (R Tapajós, at Santarem).
E. c. taczanowskii P. L. Sclater, 1886 – lowlands in N Peru (vicinity of R Marañón, both E & W of river) and extreme SE Peru and N Bolivia.
E. c. serrirostris d'Orbigny & Lafresnaye, 1837 – SE Bolivia and S Brazil (from S Mato Grosso, S Goiás and Rio de Janeiro) S to Paraguay, N Uruguay, and N & C Argentina (S to Buenos Aires).
Descriptive notes. 9–10 cm; 8–14·3 g. Small euphonia with short, thick bill. Male nominate race has bright yellow forehead and forecrown extending to just above rear of eye; rest of head and entire upperparts, including upperwing-coverts, glossy blue-black with (in good light) distinct purplish to slightly violet tinge; uppertail blackish, flight-feathers black with dark blue edges and dark blue tinge; chin to foreneck glossy blue-black, underparts bright yellow; underwing-coverts white, basal half of inner web of flight-feathers white, undertail duller than upper surface and with inner web of 2–3 outer pairs of feathers white (forming large white oval on each side of undertail); iris dark brown; bill blue-grey with blackish tip; legs dark grey. Female is olive with faint greyish tinge above, yellower on base of forehead, lores dusky; throat and underparts olive-yellow, central lower breast to belly whitish, with pale ash-grey on central belly. Immature male is like female, but mostly olive-yellow below; subadult male acquires black first on face, sometimes also black mottling on throat and underparts. Races differ rather little: *cynophora* male is strongly glossed violet above and

On following pages: 218. Trinidad Euphonia (*Euphonia trinitatis*); 219. Velvet-fronted Euphonia (*Euphonia concinna*); 220. Orange-crowned Euphonia (*Euphonia saturata*); 221. Finsch's Euphonia (*Euphonia finschi*).

on bib, has yellow of crown slightly more extensive than on nominate, underparts slightly deeper yellow, female with uniform olive-yellow underparts: *taczanowskii* male is slightly more purple above, forecrown paler yellow and ending above eye, underparts paler yellow; *amazonica* is similar to previous, but wing shorter and bill shorter, narrower and more slender, female also more greenish-yellow on forehead, lores and flanks and with yellow of forehead much less sharply demarcated; *serrirostris* is much like nominate, but yellow crown patch of male ends above (not behind) eye. Voice. Typical call a high, clear, whistled "teee, deee", this often lengthened to 3–4 notes, e.g. "teee, deee, deee", or occasionally only a single "teee", notes all on same pitch or first note slightly lower than the rest; essentially identical to calls of *E. trinitatis*. When excited, gives 1–4 rising, whistled "wheet!" notes. Infrequently heard song a jumbled series of squeaks, harsh notes and whistles. Harsh rattle also reported.

Habitat. In Amazon Basin occurs primarily along forest borders, and in river-edge and young river-island vegetation, as well as clearings with scattered tall trees; infrequently in canopy of forest. Elsewhere, in dry to humid regions in open woodland, gallery forest, forest borders, mangroves, second growth, scrub woodland, trees in pastures, in parks and gardens, and *caatinga* and *chaco* scrub. In all areas found primarily outside of forest or along forest borders, not inside forest. In E Brazil in thin, low woodland, *cerrado*, *caatinga* and palm groves, and in SE Brazil reported also from montane forest. Lowlands to c. 900 m in S Venezuela and to c. 500 m in E Colombia; c. 650–1100 m in Ecuador; to 1400 m in E Peru and 2000 m in Bolivia; in Brazil primarily in lowlands, but at higher elevations in SE coastal mountains.

Food and Feeding. Mistletoe berries (Loranthaceae), also wide variety of other small fruits, including those of figs (*Ficus*) and *Rhipsalis* (Cactaceae); some insects. Contents of ten stomachs were vegetable matter, including both fruits and seeds. Most often occurs in pairs or small family parties, less often in groups; regularly associates with other euphonias, especially in Amazonian region, and also often with mixed-species flocks. Generally forages high in tall trees, but may descend somewhat lower along forest borders. Like many congeners, feeds heavily on mistletoe berries, often spending long periods of time in mistletoe clumps high in canopy. Also examines tree branches for insects. In some areas believed to wander over wide areas.

Breeding. A nest in Paraguay was a globular domed structure with small circular side entrance, much like that of others of genus, mainly of fibres and dry leaves, lined with finer fibres, placed high up among four vertical twigs in crown of tall tree. In captivity, eggs greyish-white, marked with reddish-brown and grey, incubation by female, period c. 15 days, both adults feed chicks, by regurgitation. No other information.

Movements. Resident. Some seasonal movements in and out of dry Andean valleys (Peru) and in and out of Espírito Santo (E Brazil) reported; some seasonal wandering likely in all areas.

Status and Conservation. Not globally threatened. Widespread and fairly common to locally common. Found in wide variety of forest-edge and semi-open habitats. Occurs in many parks and reserves, and also in many unprotected areas that appear to be at little risk.

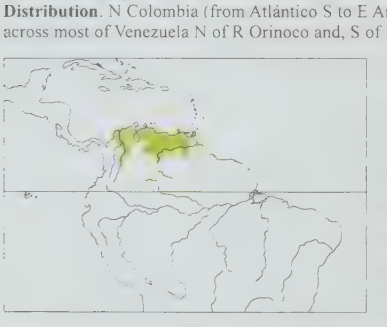
218. Trinidad Euphonia



Euphonia trinitatis

French: Organiste de Trinidad **German**: Trinidadorganist **Spanish**: Eufonia de Trinidad

Taxonomy. *Euphonia trinitatis* Strickland, 1851, Trinidad.

Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. May form a monophyletic species group with *E. affinis*, *E. luteicapilla* and *E. chlorotica*; has in the past been regarded as conspecific with last-mentioned, but differs in habitat and in female plumage. Monotypic.

Distribution. N Colombia (from Atlántico S to E Antioquia and middle Magdalena Valley) and E across most of Venezuela N of R Orinoco and, S of it, locally in NC Bolívar; also Trinidad.

Descriptive notes. 10 cm; 8·8–14 g. Small euphonia with short stubby bill. Male is glossy dark steel-blue above, with bright yellow crown extending from bill to well behind eye; bib glossy blue-black, underparts bright yellow; white underwing-coverts and white on basal half of almost all flight-feathers; basal half of outer 2–3 tail feathers with white inner webs (forming two large white ovals on undertail); iris dark brown; bill pale bluish-grey with blackish culmen and tip; legs dark grey. Distinguished with difficulty from extremely similar *E. chlorotica* by yellow forecrown patch marginally more extensive posteriorly and, in good light, dark steel-blue upperparts without distinct purple tinge. Female is olive above, dull yellowish below, with pale ash-grey median underparts; differs from *E. chlorotica* in greyish (rather than olive-yellow) central underparts, but further study needed. Immature is mainly olive above and paler olive-yellow below; subadult male shows variable amount of black mottling on throat and head. Voice. Vocal, but can be difficult to locate. Often heard call a clear, whistled "teee, deee" on even pitch, or "duuu-dee" with first note slightly lower; call sometimes of 3–4 notes; sometimes gives single "teee" or the call note lengthened, e.g. "teeeee", or any combination of the above up to c. 4 notes in a series. Song a short jumble of musical and scratchy unmusical notes, mostly unaccented. Calls and songs often alternated. All vocalizations virtually identical to those of *E. chlorotica*, also quite similar to those of many other congeners.

Habitat. Dry to moist forest, gallery forest, light woodland, forest borders, scrubby or wasteland areas, and pastures and cultivated areas with scattered trees and tree-lined borders, also residential areas (cf. more forest-based *E. chlorotica*). Sea-level to c. 600 m; locally (or seasonally) to 1100 m in Colombia and to 1450 m in N Venezuela.

Food and Feeding. Small fruits and berries, especially mistletoe berries (Loranthaceae), also insects. Occurs in pairs and in small groups of 3–6 individuals, occasionally as many as ten, and may roost in gatherings of a dozen or more; groups of varying composition, sometimes mostly males, sometimes mostly female-plumaged birds; infrequently associates with mixed-species flocks (few form in areas that it inhabits), but readily joins other species to mob small owls (Strigidae), snakes and other predators. Forages from middle levels to canopy, and often perches quite high when calling. Wanders widely, taking many small fruits and berries. Gleans insects from high, bare twigs, spider webs, etc.

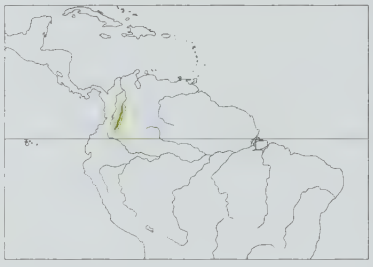
Breeding. Breeding reported in Apr in Colombia and Venezuela and Feb–Apr in Trinidad. Nest built by both sexes, a globular covered structure with small, circular side entrance, made mostly from grass, usually located in cluster of small twigs 1·4–12 m up near end of branch in tree. Clutch 3–4 eggs, pale cream or white, marked with shades of brown; incubation by female, chicks fed by both sexes; no information on duration of incubation and nestling periods.

Movements. Resident.

Status and Conservation. Not globally threatened. Fairly common to common virtually throughout its range. Occurs in a number of reserves and protected areas, including Guatopo, Henri Pittier, San Esteban, Morrocoy and Terepaima National Parks (Venezuela) and Serranía de Macuira, Morichales de Paz de Ariporo and El Tuparro National Parks (Colombia). This species utilizes a wide variety of dry semi-open habitats that, although unprotected, are at little risk.

Bibliography. Allen (1905), Belcher & Smooker (1937), Cherrie (1916), Darlington (1931), ffrench (1991), Friedmann & Smith (1950), Hellmayr (1935, 1936), Hilty (2003), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1966, 1970a), Meyer de Schauensee & Phelps (1978), Restall *et al.* (2006), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008), Schäfer & Phelps (1954), Snow & Snow (1971), Thomas (1982), Zimmer (1943a).

219. Velvet-fronted Euphonia



Euphonia concinna

French: Organiste du Magdalena **German**: Samtstirnorganist **Spanish**: Eufonia del Magdalena

Taxonomy. *Euphonia concinna* P. L. Sclater, 1855, "Bogotá".

Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Monotypic.

Distribution. WC Colombia, in upper Magdalena Valley from N Tolima (Honda) and adjacent Cundinamarca S to SW Huila (La Plata); recent record from middle Cauca Valley.

Descriptive notes. 9 cm; 9–12 g. Small euphonia with small, stubby bill. Male has small yellow forecrown patch extending rearwards just to eye, bordered in front by narrow band of black over bill (difficult to see in field); otherwise head to foreneck and upperparts, including upperwing-coverts, blue-black with purplish gloss; tail blue-black, flight-feathers black, usually small white spot at base of outer primaries (amount of white variable, sometimes absent); breast and lower underparts rich ochraceous to cinnamon-yellow; iris dark brown; bill pale bluish-grey with blackish culmen and tip; legs dark grey. Differs from similar *E. chlorotica* and *E. trinitatis* in having narrow black band across base of forehead and only small yellow patch on forecrown, also darker undertail with no white patches. Female has inconspicuous olive-yellow anterior superciliary stripe, with most of crown, ear-coverts and nape light olive-grey, becoming olive on rest of upperparts; uniformly dull yellowish, tinged olive, below. Immature apparently undescribed. Voice. Frequently heard call, by either sex, a clear high "dee-dee" or "tee dee-dee", much like that of many others of genus. Song, by male (possibly also female) a slightly gravelly and varied series of phrases, e.g. "p'wheeet-wheeet...pa'weet, whe'e'e't, whe'e'e't...pa'weet, p'bzrrrr, bzrrrr...", the "wheeet" notes rising in pitch, sometimes slightly burry; "bzrrrr" notes buzzy or rattling.

Habitat. Found in dry open and semi-open woodland, ranchland with scattered trees, fence rows with trees, and light woodland along streams. At 200–1000 m, and recorded locally to 1800 m in W Cundinamarca; principally in dry lower-elevation sites.

Food and Feeding. Small fruits and berries, especially mistletoe berries (Loranthaceae); probably some insects, too. Occurs in pairs or small family parties, most often seen apart from other species; less frequently loosely associated with a few other species. Like congeners, stays well up in trees and often feeds on mistletoe berries. Can be remarkably confiding and easy to see.

Breeding. Three birds in breeding condition in Jan–Apr in upper Magdalena Valley. No other information.

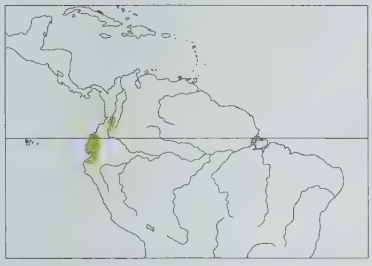
Movements. Resident. Limited observations suggest that pairs or families are sedentary, and not so apt to wander as do some other members of genus (e.g. *E. trinitatis*) that occur in dry semi-open areas.

Status and Conservation. Not globally threatened. Restricted-range species: present in Colombian Inter-Andean Valleys EBA. Fairly common very locally. Recent record from middle Cauca Valley needs confirmation; possibly relates to an escaped cagebird. There are no parks or reserves within this species' range, which does, however, include extensive scrub, ranchland, riverine woodland and dry semi-open areas which are at little risk of development and are apparently suitable for the requirements this species.

Bibliography. Hilty (2009a), Hilty & Brown (1986), Isler & Isler (1999), Meyer de Schauensee (1964, 1966, 1970a), Miller (1947), Olivares (1969), Restall *et al.* (2006), Ridgely & Tudor (1989, 2009), Salaman *et al.* (2008).

220. Orange-crowned Euphonia

Euphonia saturata



French: Organiste à calotte d'or **Spanish**: Eufonia Coroninaranja
German: Orangescheitelorganist

Taxonomy. *Phonasca saturata* Cabanis, 1861, "Bogotá".

Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Monotypic.

Distribution. Colombia on both slopes of W Andes (in Valle, probably also Cauca), and W Ecuador S to extreme NW Peru (Tumbes).

Descriptive notes. 10 cm. Small, relatively dark euphonia with rather short and thick bill. Male has entire crown (back almost to nape) deep orange-yellow; rest of head to foreneck and upperparts, including upperwing-coverts and flight-feathers, glossy blue-black with purplish tinge; uppertail

blue-black; breast and lower underparts, including undertail-coverts, deep orange ochraceous; undertail plain dark grey; iris dark brown; bill blackish, base of lower mandible pale grey; legs dark grey. Differs from similar *E. xanthogaster* in lack of white on underside of tail. Female is entirely dark olive above, dull olive-yellow below, slightly paler and more yellowish on throat and especially on belly and undertail-coverts, with sides and flanks tinged olive; undertail-coverts with faint olive tinge. Juvenile undescribed. Voice. Song a leisurely series of "tsit" notes, nasal "tcheeur" notes, and fast "tididit" phrases. Call a high, clear whistled "pee-deet", much like that of *E. trinitatis* and many other members of genus.

Habitat. Occurs in wide variety of semi-open areas with scattered trees, parks, tree-lined streamsides, woodlots, in dry valleys with deciduous forest, and locally along semi-humid and wet forest borders and humid clearings with trees. May be found with greater frequency in drier habitats in S Ecuador. Generally at 700–1300 m. locally up to c. 1800 m, in Colombia; from near sea-level to locally as high as 1500 m in Ecuador.

Food and Feeding. Few data available on diet; probably feeds mainly on small berries and fruits. Usually singly or in pairs that stay well up in trees in rather open areas; has been found with mixed tanager–honeycreeper flocks at c. 900 m on steep forested slopes in SW Colombia. Arboreal; behaviour much like that of other members of genus.

Breeding. Nest-building in Apr in S Colombia (Pialapi Valley, 1790 m, in SW Nariño: nest built by female, globular, with side entrance, made from grass, rootlets, bamboo leaves and moss, placed in epiphytes close to trunk at edge of pre-montane forest. No other information.

Movements. Little information. Recorded only Feb–Mar (single adult males) in Anchicayá Valley (at 1050 m), in W Colombia, suggesting seasonal or post-breeding dispersal.

Status and Conservation. Not globally threatened. Uncommon and local both in SW Colombia and in W Ecuador. May occur in a few protected areas, e.g. Farallones de Cali National Park and El Pangan Reserve, in W Colombia. The species' range includes a variety of habitats, some intact, some heavily intervened, in both Colombia and Ecuador; its utilization of wooded borders and semi-open areas should provide a buffer and a measure of protection against short-term risk.

Bibliography. 221. Finsch's Euphonia

Euphonia finschi

French: Organiste de Finsch **German**: Finschorganist **Spanish**: Eufonia de Finsch

Taxonomy. *Euphonia finschi* P. L. Sclater and Salvin, 1877, Demerara, Guyana.

Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Monotypic.

Distribution. Venezuela (near Santa Elena de Uairén and specimen from near Cerro Roraima, both in extreme SE Bolívar), adjacent N Brazil (NE Roraima) and E across C Guyana, W & N Suriname and N French Guiana.

Descriptive notes. 9 cm; 10–11 g. Small euphonia with bill relatively short and thin for genus. Male has small dark yellow forecrown patch extending to rear of eye; rest of head to foreneck and upperparts, including upperwing-coverts and flight-feathers, glossy purplish-black, inner webs of flight-feathers white at base (forming small spot or patch not always visible when bird at rest; conspicuous white band in flight); uppertail dark steel-blue; breast and all of lower underparts deep tawny-orange, lower breast and sides tinged reddish-brown (burnt orange); undertail plain slate-grey; iris brown; bill pale blue-grey with blackish tip; legs and feet dark grey. Female is olive above, slightly yellowish on forecrown, with faint dusky area through eye; olive-yellow below, becoming plain dull yellow on centre of belly; no white in tail and no white band in wing. Juvenile apparently undescribed. Voice. Call a clear, whistled "dee-dee", this varied to "dee-dee-dee", or even to 4 notes, and overall much like that of *E. chlorotica* and *E. trinitatis*, but given a bit more slowly. Also a clear "beeee".

Habitat. Found primarily along gallery-forest borders, bushy savanna with scattered trees and, in Suriname, also along borders of humid forest in sandy-soil regions. In all areas seems strongly associated with sandy-soil savanna where patches of woodland and scattered trees present. To 1200 m in SE Venezuela, and presumably at similar elevations in adjacent Guyana; recorded at up to c. 400 m in Suriname and French Guiana.

Food and Feeding. Small fruits and berries, e.g. mistletoe berries (Loranthaceae); probably some insects. Pairs or small groups (possibly families), often consisting of several female-plumaged birds and an adult male, wander along gallery-forest borders and call and chatter from treetops, or fly off swiftly in bounding flight to visit distant fruiting trees and shrubs. One or several often perch together on high, bare twigs and call. In savannas of N Suriname has been seen to feed at berry-laden shrubs in association with *E. minuta*, *E. plumbea* and *E. chrysopasta*; in Sipaliwini Savanna of S Suriname has been found with *E. minuta*.

Breeding. Male with greatly enlarged gonads in mid-Apr in Suriname. No other information.

Movements. Resident. Any movements likely confined to short-distance seasonal wandering; has been found only irregularly at a site near Santa Elena de Uairén, in extreme SE Venezuela, suggesting some seasonal movement.

Status and Conservation. Not globally threatened. Generally uncommon and perhaps also very local throughout its range; can be difficult to find and seems nowhere very numerous. Occurs in a few protected areas, most notably the Central Suriname Nature Reserve (World Heritage Site). There appear to be few threats to the habitat occupied by this species, and it is likely, also, to survive in partly disturbed areas.

222. Violaceous Euphonia

Euphonia violacea

French: Organiste teité **German**: Veilchenorganist **Spanish**: Eufonia Violácea

Taxonomy. *Fringilla violacea* Linnaeus, 1758, Suriname.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Race *rodwayi* weakly differentiated, and perhaps better subsumed in nominate. Three subspecies recognized.
Subspecies and Distribution.
E. v. rodwayi (T. E. Penard, 1919) – E & S Venezuela and Trinidad.
E. v. violacea (Linnaeus, 1758) – the Guianas, and N Brazil (N of R Amazon E of R Jamundá; S of Amazon from R Madeira E to Maranhão).
E. v. aurantiicollis A. Bertoni, 1901 – E Brazil (Piauí S to Goiás, Minas Gerais and Rio de Janeiro, then W to W Paraná and S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

Descriptive notes. 10 cm; 12·5–17 g. Rather small euphonia with bill relatively heavy for the genus. Male nominate race has orange-yellow forecrown patch extending just to front edge of eye; rest of crown, side of head, nape and upperparts blue-black, highly glossed purplish; uppertail blue-black; upperwing-coverts glossy blue-black, flight-feathers dusky, tinged blue-black; throat and breast orange-yellow, fading into rich yellow of rest of underparts; underwing-coverts and basal half of inner webs of all except outer 2–3 flight-feathers white (usually concealed, sometimes visible in flight); underside of tail dull dark grey, inner webs of outer two or three feather pairs white (forming two large white oval patches on underside of tail); iris dark brown; bill blackish, basal two-thirds of lower mandible blue-grey; legs dark grey. Female has forehead yellowish, turning olive on crown and rest of upperparts, including upperwing-coverts; flight-feathers dusky, tinged olive; underparts bright olive-yellow, belly and undertail-coverts yellow; essentially identical to female of *E. laniirostris*. Immature is like female; subadult male olive above, forecrown yellowish, mottled olive, sides of head black, forming mask, throat yellow and median underparts yellow, sides, flanks and lower underparts olive. Race *aurantiicollis* differs from nominate in larger size, male with yellow on forehead broader, crown and nape frequently more strongly glossed with violaceous; *rodwayi* male differs little from nominate, but very slightly larger (some individuals almost as large as *aurantiicollis*). Voice. Songs incorporate mimicked notes and phrases of many other birds, including both oscine and non-oscine species, which are typically not separated from other phrases in song. Song elements vary widely in pitch, and quality of mimicked phrases also varies, some individuals giving long series of remarkably accurate imitations, others less so. Calls include variety of whistles and short trills, some musical, others unmusical, raspy or metallic. Songs incorporate many of the same whistles and trills in long rambling diatribes that also contain short rattles and various other notes.
Habitat. Humid forest, forest borders, second-growth woodland, shrubby clearings with taller trees, orchards, parks, and trees around buildings; in Brazil and elsewhere seems to require forest or some woodland within its territory. Lowlands, to as high as 1100 m in SE Venezuela.
Food and Feeding. Fruits; also, reported as taking nectar from *Psittacanthus* mistletoe (Loranthaceae) in Brazil, and *Allophyllus edulis* (Sapindaceae) fruit in Paraguay. In Suriname reported as eating berries of mistletoe (including *Phithirusa*), *Rhipsalis*, *Ficus* and *Trema*. In Trinidad study, of 206 observations of foraging, almost all (97%) involved fruit; of these, 62% were small berries of epiphytes and parasites, including a bromeliad, *Aechmaea mudicaulis* (18%), *Rhipsalis* (16%) and mistletoe (14%). Contents of stomachs entirely seeds and fruit. Found singly, in pairs and in small groups, alone or sometimes with other birds at fruiting trees or when mobbing small owls (Strigidae) and other predators. Forages from shrub level to treetops, mostly in upper levels and canopy of trees, and regularly perches in open atop large trees to call or rest. In Trinidad median foraging height was c. 6 m. Takes fruit by hovering or by hanging downwards, as well as perching upright. Berries swallowed whole, mashed to remove skin, or pieces pecked from larger fruits, such as catkins of *Piper* and *Cecropia*.
Breeding. Breeding reported Jan–Aug (mostly May–Jul) in Trinidad, Nov–Apr in Suriname and Oct in Brazil. Nest built by both sexes, a globular structure with small circular entrance on side, made from dead leaves, grass, rootlets, moss, etc., lined with ferns and grass, typically well hidden among epiphytes, in vines on tree trunk, occasionally in niche in roadside bank; sometimes appropriates unused nest of other species, e.g. Rusty-margined Flycatcher (*Myiozetetes cayanensis*). Clutch 3–5 eggs, dull white to pinkish-white with light to dark reddish spots, mostly at larger end; incubation by females alone, no information on duration; both adults feed young, nestling period unusually long for a small passerine, c. 21 days.
Movements. Resident. May wander seasonally in search of fruit.
Status and Conservation. Not globally threatened. Fairly common to common, and widespread. Occurs in a number of protected areas, ranging from Canaima National Park (Venezuela), Kaieteur National Park (Guyana) and Brownsberg, Voltzberg and Sipaliwini Nature Parks (Suriname) S to Iguazú National Park (Argentina) and Itatiaia and Tijuca National Parks (SE Brazil). The species' range also contains vast areas of suitable habitat which is unprotected (especially across E Amazonia), but unlikely to suffer any serious near-term damage.

223. Thick-billed Euphonia

Euphonia laniirostris

French: Organiste à bec épais **German**: Dickschnabelorganist **Spanish**: Eufonia Piquigruesa

Other common names: Black-tailed Euphonia (*melanura*)

Taxonomy. *E.*[*uphonia*] *laniirostris* d'Orbigny and Lafresnaye, 1837, Yuracares, Bolivia.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Race *zopholega* doubtfully distinct from nominate. Five subspecies currently recognized.
Subspecies and Distribution.
E. l. crassirostris P. L. Sclater, 1857 – Pacific slope of Costa Rica (from Guanacaste) S to Panama (both slopes from Coclé E through Darién) and N Colombia (S on Pacific coast to C Chocó, throughout Cauca Valley and Magdalena Valley; also in Arauca and Boyacá), and across N & W Venezuela (E to W Sucre, and S in *llanos* almost to R Orinoco).
E. l. hypoxantha Berlepsch & Taczanowski, 1884 – Pacific coast of Ecuador S to NW Peru (S Cajamarca).
E. l. melanura P. L. Sclater, 1851 – E Colombia (from Meta and Vichada) S through E Ecuador and E Peru (S to San Martín and N Ucayali), and C Brazil (Acre and generally E across Amazon Basin S of R Amazon to W Pará).
E. l. zopholega (Oberholser, 1918) – EC Peru (Junín and Cuzco).
E. l. laniirostris d'Orbigny & Lafresnaye, 1837 – SE Peru and N Bolivia E to C Brazil (SE Amazonas and C Mato Grosso).

Descriptive notes. 10 cm; 13–16·5 g. Rather small euphonia with relatively thick bill deeper than that of most congeners. Male nominate race has yellow forehead to mid-crown (a little past eye); side of head, rear crown, nape and upperparts glossy blue-black; uppertail dark blue; upperwing-coverts and flight-feathers dusky, tinged dark blue; throat and entire underparts bright yellow; undertail dark grey, inner webs of outer 2–3 feather pairs mostly white (forming two large white ovals on undersurface of tail); iris dark brown; bill blackish, base of lower mandible blue-grey; legs dark grey. Female is yellowish olive-green above, greenish-yellow below, paler on undertail-coverts. Immature is similar to female; subadult male (second full year) is olive above, forecrown yellow with olive mottling, variable amount of black on side of head (usually forming mask), throat and chest yellow, sides, flanks and lower underparts mostly olive. Race *crassirostris* male is similar to nominate, but yellow of crown extends farther backwards, especially in centre; *hypoxantha* male differs in having whole crown lemon-yellow, and underparts lighter and brighter yellow; *melanura* male has crown like nominate, but underparts darker, orange-yellow, and undertail entirely dark grey (no white), female similar to nominate, but darker below; *zopholega* male is similar to nominate, but white ovals on undertail smaller. Voice. A good mimic of other birds' vocalizations, especially of alarm and contact calls. Song a long rambling series of original notes and mimicked notes of other birds. Both sexes, but especially males, give wide variety of calls, including loud, sharp, whistled "preet!", harsh, buzzy rattles, "tz'i'i'i'i't", and many semi-musical notes and phrases.
Habitat. Occurs in a wide variety of partly open habitats, including woodlots, clearings with trees, forest borders, gallery forest, second-growth woodland, plantations, cultivated areas, and trees around habitations in relatively dry to humid regions. Within Amazonian portion of range found mainly along forest borders of floodplain-forest or *várzea* forest, along river edges, in various age stages of river-island vegetation, and in trees in clearings and second growth. Lowlands up to 1200 m in Panama; to 1900 m in Venezuela; to c. 2200 m (most records below 1100 m; rarely to 2400 m) in Colombia, to c. 1500 m and on W slope locally to 1800 m in Ecuador; to 2000 m in Urubamba Valley, in Peru.
Food and Feeding. Small fruits and berries. Mistletoe (Loranthaceae) comprises a large proportion of diet, but also eats berries of melastomes, figs (*Ficus*) etc.; in Colombia recorded as eating fruits of *Aiphanes* (a spiny palm) and *Sapium* (Euphorbiaceae). Contents of five stomachs were vegetable matter, including fruit and seeds. Found mostly in pairs or small groups that forage and wander alone or sometimes associate with mixed-species flocks along wooded borders; also sometimes with other members of genus, especially around mistletoe. Like many euphonias, may rest or call from high or semi-open perch. Forages mostly in higher part of trees; occasionally drops low along shrubby borders.
Breeding. Breeding reported in Mar–Sept in Panama, and season probably similar in Costa Rica; Dec and Jan and birds in breeding condition in Apr–Jul in Colombia; nest-building observed in early Mar in SW Ecuador (at Tambo Negro, in Loja); two, rarely three, broods in a year reported. Nests of some pairs visited by possible helpers, but feeding of nestlings by latter not verified. Nest built by both sexes, but female may reweave much of her mate's contribution; a globular structure with small circular entrance on side, sometimes also with small porch or overhang, composed of fine twigs, fibres and leaves, lined with dry grass, usually built on or within 3 m of ground, occasionally much higher (to 15 m in Venezuela), generally well hidden in cavity in trunk, post, on epiphyte-covered or vine-covered limb, or branch fork; nest occasionally reused (such reused nests found to be lined with strips of dried *Heliconia* or banana leaves); reported also as appropriating nest of Great Kiskadee (*Pitangus sulphuratus*) built c. 6 m up and atop nest of a thornbird (*Phacellodomus*). Clutch 2–5 eggs, white or pinkish-white, speckled and marked with brown, especially at large end; at two nests, incubation period 14–16 days, chicks fed by both parents, nestling period 18–21 days. Male may breed in subadult plumage, when in second full year.
Movements. Resident.
Status and Conservation. Not globally threatened. Fairly common to common, and widespread, especially E of Andes. Occurs in numerous protected areas from Panama S to Bolivia, and thrives in variety of habitats, including second growth, wooded borders and disturbed and settled areas. Although vast majority of habitat where it occurs is unprotected, this species appears to be at little risk in the near term.

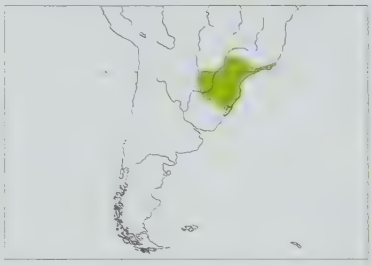
224. Yellow-throated Euphonia

Euphonia hirundinacea

French: Organiste à gorge jaune **German**: Schwalbenorganist **Spanish**: Eufonia Gorjiamarilla
Other common names: Bonaparte's Euphonia

Taxonomy. *Euphonia hirundinacea* Bonaparte, 1838, Guatemala.
Recent molecular-genetic analysis indicates that genus belongs in family Fringillidae. Three further proposed Mexican races, *suttoni* (described from Rio Sabinas, near Gómez Farías, in SW Tamaulipas), *russelli* (from 2 km NE of Felipe Carrillo Puerto, in Quintana Roo) and *caribbaea* (from Monte Bello, N of Palomares, in Oaxaca), all now subsumed into nominate. Two subspecies recognized.
Subspecies and Distribution.
E. h. hirundinacea Bonaparte, 1838 – E & SE Mexico (from San Luis Potosí, S Tamaulipas, Puebla, N Oaxaca, Chiapas and Yucatán Peninsula) S through Belize, Guatemala, Honduras, El Salvador and E Nicaragua.
E. h. gnatho (Cabanis, 1861) – NW Nicaragua and Costa Rica (in Guanacaste, and C valley and Caribbean slope) S to W Panama (W Chiriquí).



Descriptive notes. 10 cm; 11·6–17·8 g. Small euphonia with small yellow forecrown. Male nominate race has small bright yellow patch on forehead extending back to eye; rest of head and upperparts, including upperwing-coverts, glossy blue-black, uppertail blue-black; flight-feathers dusky, edged and tinged blue-black; throat and entire underparts bright yellow; underwing-coverts white; undertail dark dull grey, inner webs of outer 2–3 feather pairs mostly white (forming large, white, oval-shaped area on each side of undersurface); iris dark brown; bill blue-grey with blackish tip; legs dark grey. Female has top and side of head and upperparts olive; throat, centre of breast and lower underparts whitish to greyish-white, sides, flanks and undertail-coverts yellowish-olive. Juvenile male is much like female; immature male (especially older subadult) also resembles female, but generally with black mask or with black on crown and head (similar to that of adult male), or with crown mixed black and olive, otherwise like female, underparts yellow to yellowish, washed olive on sides. Race *gnatho* differs from nominate in having larger, more swollen bill, male with gloss more bottle-green (less bluish), female with more yellowish underparts. Voice. Song of male includes high shrill and squeaky notes often rapidly alternated in choppy pattern of 2–4 notes, some notes clear and bell-like, others plaintive; some songs reportedly included mimicked notes of other birds, but with repertoire much smaller than that of *E. violacea* (also a vocal mimic). Calls include rolling "cheek-chereeg", scratchy, unmusical "chee-cheet", metallic "weet", and bright "chi-chi-chit" or "ji-ji-jit"; also "sseeu" or "speeu"; also a variety of other sharp and liquid notes. Female gives thin, dry notes, some high-pitched, some trilled.
Habitat. Found in dry to humid regions, mainly along forest borders, second growth, shady plantations, and riverine forest; generally scarce or absent in regions of extensive humid forest including pine (*Pinus*) forest. Lowlands to c. 2100 m, mainly to c. 1500 m, in Mexico; primarily in plateau and hill country in El Salvador and C Costa Rica; presumed to occur in foothills between c. 900 m and 1200 m in W Panama.
Food and Feeding. Fruits and berries; probably also insects. Feeds heavily on mistletoe berries (Loranthaceae), and locally feeds heavily on figs (*Ficus*). Stomach contents have consisted of mistletoe berries. Nestling diet mostly fruit. Berries swallowed whole or mashed. Pairs or small groups reported as wandering over rather large areas when foraging; in Mexico often with *E. affinis*. Appears to search for insects by working along small branches, in foliage and at heads of palms, and investigates moss clumps and epiphytes.
Breeding. Breeding reported in May and Aug in Mexico, Jun in Belize, Mar–May in Guatemala, and mainly Apr–Jul at in Costa Rica (Monteverde). Nest a ball with side entrance, made from grass, fine tendrils and other vegetation, placed at variable height, from eye level to 15 m up, in niche in streambank, in roadside bank, on tree trunk, branches or palm frond, within epiphytes or in clump of moss. Clutch c. 5 eggs, white, lightly spotted brownish at larger end; incubation by female, period c. 16 days; chicks fed by both parents, by regurgitation, adults visit nest infrequently to feed young, usually arrive together, accompany one another to nest entrance in what may be distraction display; nestling period at least 17 days.
Movements. Resident over most of range; some local seasonal movements in response to food abundance likely. In Mexico, considered probably only non-breeding visitor, Oct to early May, on Pacific slope of Isthmus of Tehuantepec, in Oaxaca.
